Table of Contents

C. elegans DEVELOPMENT, CELL BIOLOGY AND GENE EXPRESSION MEETING

Plenary and Platform Session Abstracts

C. elegans Development, Cell Biology And Gene Expression Meeting

SCHEDULE AT-A-GLANCE

Wednesday, July 13		
2:00pm-9:30pm	Speaker Ready Room Open	Hall of Cities - Anaheim
7:00pm-9:00pm	Scientific Session: Plenary Session 1: Germline Dynamics	Grand Ballroom 8A
9:00pm-11:00pm	Opening Mixer with Exhibits	Cypress Ballroom
Thursday, July 14		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities -Anaheim
7:45am-10:00am	Genetics and Determinants of Health Joint Plenary Session	Palms Ballroom
8:00am-4:00pm	Exhibits Open	Cypress Ballroom
9:00am-8:00pm	Demo Room: MOD (FlyBase, MGI, SGD, WormBase, Zfin) Demo Room Open	Palms Ballroom Canary 3-4
10:30am-12:30pm	Scientific Session: Genomics, Gene Regulation and Technology	Grand Ballroom 8A
12:30pm-1:30pm	Mentoring Roundtables #1	North Tower - Harbor Beach
12:30pm-1:30pm	Speaking Up for Genetics and Model Organism Research	Crystal Ballroom H
1:30pm-3:30pm	Poster Presentations 1:30pm-2:30pm: Even-numbered posters 2:30pm-3:30pm: Odd-numbered posters t	Cypress Ballroom
1:30pm-3:30pm	GeneticsCareers Center and Job Fair	Cypress Ballroom 1C
4:00pm-6:00pm	Scientific Session: Intracellular Organelles, Trafficking, and the Cytoskeleton	Grand Ballroom 8A
4:00pm-6:00pm	Plenary Session and Workshop for Undergraduate Researchers	North Tower - Sawgrass
7:45pm-9:45pm	Scientific Session: Plenary Session 2: Systems Biology	Grand Ballroom 8A
10:00pm-11:30pm	*Science Cafe Event	Palms Ballroom Sabal
Friday, July 15		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities - Anaheim
8:00am-9:30am	Scientific Session: Aging and Cell Death	Grand Ballroom 8A
8:00am-4:30pm	Exhibits Open	Cypress Ballroom
9:00am-8:00pm	Demo Room: MOD (FlyBase, MGI, SGD, WormBase, Zfin) Demo Room Open	Palms Ballroom Canary 3-4
10:00am-11:00am	Scientific Session: Cell Cycle, Cell Division, Cytokinesis	Grand Ballroom 8A
11:00am-12:00pm	Scientific Session: Cell Polarity and Cell Fate	Grand Ballroom 8A
12:00pm-1:30pm	*Editor's Panel Discussion and Roundtable	North Tower - Harbor Beach
1:30pm-3:30pm	Poster Presentations 1:30pm-2:10pm: "A" poster authors present 2:10pm-2:50pm: "B" poster authors present 2:50pm-3:30pm: "C" poster authors present	Cypress Ballroom
1:30pm-3:30pm	GeneticsCareers Center	Cypress Ballroom 1C

** Ticketed Event*

#TAGC16

Friday, July 15 (continued)		
2:00pm-2:45pm	GeneticsCareers Workshop - Nailing the Job Talk	Cypress Ballroom 1B
4:00pm-6:00pm	Scientific Session: Cell Patterning and Morphogenesis	Grand Ballroom 8A
6:00pm-7:30pm	*Women in Genetics Panel and Networking	North Tower - Harbor Beach
7:30pm-9:30pm	Development and Evolution Joint Plenary Session	Palms Ballroom
Saturday, July 16		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities - Anaheim
8:00am-10:00am	Workshops: See topics and descriptions under the Workshop Section	Multiple locations
8:00am-12:00pm	Exhibits Open	Cypress Ballroom
8:00am-9:00am	Trainee Bootcamp Workshops: Session 1	North Tower
9:00am-10:00am	Trainee Bootcamp Workshops: Session 2	North Tower
10:00am-12:00pm	Poster Presentations 10:00am-11:00am Odd-numbered posters 11:00am-12:00pm Even-numbered posters	Cypress Ballroom *(Posters must be removed by 1pm)*
10:00am-12:00pm	GeneticsCareers Center	Cypress Ballroom 1C
10:30am-11:15am	GeneticsCareers Workshop	Cypress Ballroom 1B
12:15pm-1:45pm	*Mentoring Roundtables #2	North Tower - Harbor Beach
1:45pm-3:45pm	Scientific Session: Meiosis, Germ Line Development, and Sex Determination	Grand Ballroom 8A
4:00pm-6:00pm	Scientific Session: RNAi, microRNAs, and Developmental Timing	Grand Ballroom 8A
4:00pm-6:00pm	Workshop: You Can Publish That, Too - Publishing Education Resources	North Tower Bahamas
7:30pm-9:30pm	Scientific Session: Plenary Session 3: Development and Disease	Grand Ballroom 8A
Sunday, July 17		
10:30am-12:30pm	Technology and its Application Joint Plenary Session	Palms Ballroom

** Ticketed Event*

W397 Domestication of *C. elegans* Sperm. *Michael Miller*. Univ Alabama at Birmingham, Birmingham, AL.
no abstract submitted

W398 Visualization and quantification of the transcriptional response to GLP-1/Notch signaling in the germline stem cell niche. *Judith Kimble*[1,2], ChangHwan Lee[1,2], Erika Sorensen[1,2]. 1) Univ. Wisconsin, Madison, WI; 2) HHMI.

Notch signaling regulates stem cells, proliferation and differentiation throughout the animal kingdom. In the *C. elegans* gonad, the somatic distal tip cell (DTC) niche uses GLP-1/Notch signaling to maintain germline stem cells (GSCs), which generate, maintain and regenerate the germline tissue. We recently identified the *sygl-1* gene as a direct downstream target of GLP-1/Notch transcriptional activation and key GSC regulator (1). Here we use single molecule fluorescence *in situ* hybridization (2) to visualize *sygl-1* transcripts in germ cells of the progenitor zone, the region harboring GSCs. Using exon- and intron-specific probes, we distinguish active transcription sites (ATS) in nuclei and mature transcripts in the cytoplasm. With a custom MATLAB code, we record number, intensity and spatial coordinates of both ATS and mRNAs. This approach provides a direct and quantitative readout of the endogenous transcriptional response to GLP-1/Notch. In wild-type germlines, *sygl-1* ATS occur stochastically, with little correlation between intensities in a nucleus or with cell cycle stage. Yet the response is patterned: ATS are restricted to the distal ~1/3 of the progenitor zone, and within that region, the percent nuclei with *sygl-1* ATS is graded, from 65% at the distal end to <5% 30 µm or 7 germ cell diameters from the distal end. The *sygl-1* transcriptional response is gone in *glp-1* null mutants, expanded in *glp-1* gain of function mutants, abolished within 30 minutes after shifting *glp-1(ts)* to restrictive temperature and less robust than wild-type in *glp-1(ts)* mutants at permissive temperature. Comparison of readouts in wild-type and *glp-1(ts)* at permissive temperature reveals how the response varies as a function of signaling strength: weaker signaling leads to fewer ATS-positive nuclei, lower ATS signal intensity and shorter ATS extent from the DTC. To learn how the graded ATS spatial pattern is generated, we used *glp-1(ts)* to turn off GLP-1/Notch and abolish ATS and then turn it back on to monitor how fast the ATS signals reform. Their pattern was fully regenerated within an hour, too fast for the main patterning mechanism to be signal decay as germ cells move proximally within the niche. We suggest instead that the strength of GLP-1/Notch signaling is graded in the distal progenitor zone. The major conclusions are that the transcriptional response to Notch signaling is stochastic and that signaling strength determines probability and intensity of transcriptional firing. This high resolution view of the Notch transcriptional response in stem cells will serve as a paradigm for analyzing the readout of signaling more generally.

W399 Dynein subunit DLC-1 promotes localization and function of stem cell regulator FBF-2 in *C. elegans*. *X. Wang*[1], M. Ellenbecker[1], J. Olson[1], J. Bailey[1], D. Rasoloson[2], E. Voronina[1]. 1) University of Montana, Missoula, MT; 2) Johns Hopkins University School of Medicine/HHMI, Baltimore, MD.

PUF family RNA-binding proteins are conserved eukaryotic mRNA regulators. FBF-1 and FBF-2, two PUF family proteins in *C. elegans*, are translational repressors required for maintenance of germline stem cells (Crittenden et al., 2002). FBF-1 and FBF-2 are very similar to each other but employ different mechanisms to silence target mRNAs. FBF-2 function depends on its localization to P granules, RNA granules of germ cells (Voronina et al., 2012). In this study, we found that dynein light chain DLC-1 is required for FBF-2 recruitment to P granules. To understand the role of cofactors in FBF-2 function, we characterized FBF-2 interactome by mass-spectroscopy. By genetic interaction assay, *dlc-1* was identified as a component of FBF-2 RNP specifically contributing to FBF-2-mediated regulation. One known role of DLC-1 is aiding assembly of the dynein motor complex involved in trafficking of organelles, proteins and mRNAs. Knock-down of *dlc-1* by RNAi leads to dispersion of FBF-2 from P granules and decreased FBF-2 regulatory activity. However, FBF-2 localization and activity are not affected by depletion of dynein motor subunit, suggesting DLC-1 cooperates with FBF-2 in dynein-independent manner. In the in vitro pulldown assay, DLC-1 interacts with FBF-2, but not FBF-1. Typically, LC8 associates with its partner proteins through the KXTQT or GIQVD recognition sequence. However, FBF-2 does not contain canonical LC8 recognition sites. To investigate how FBF-2 interacts with DLC-1, we are determining the structure of DLC-1 bound to one of the DLC-1-binding regions of FBF-2. Preliminary data suggests that FBF-2 peptide binds the same site on DLC-1 as DLC-1's conventional partners. To test whether FBF-2 localization depends on direct interaction with DLC-1 in vivo, we generated FBF-2 mutant transgene with mutations of DLC-1 binding sites. The FBF-2 mutant dispersed away from P granules, suggesting that direct interaction with DLC-1 is required for FBF-2 perinuclear localization in vivo. In vitro RNA binding assay suggested that FBF-2 mutant binds target RNA with same affinity as wildtype FBF-2.

LC8 light chains are now recognized as regulatory hub proteins essential for diverse protein networks. Our finding of cooperation between FBF-2 and DLC-1 introduces the idea that DLC-1 homologs directly impact regulatory networks affecting germline stem cell maintenance. This insight will advance understanding of regulatory mechanisms of germline stem cell maintenance in other organisms, including humans.

W400 After extrusion, the second polar body is internalized via receptor-mediated phagocytosis in *C. elegans* embryos. *A. M. Wehman*, G. Fazeli, B. Karmann, E. Schruf. Uni Würzburg, Würzburg, Bayern, DE.

Polar bodies are commonly used for preimplantation genetic diagnosis in human embryos. During egg development, polar bodies are extruded to expel the extra DNA made during Meiosis and to form a haploid oocyte. In contrast to the well-studied mechanisms of polar body extrusion, their fate after extrusion is unknown in any system.

We studied the fate of polar bodies using time-lapse imaging of fluorescent reporter strains and a panel of *C. elegans* mutants. We found that the first polar body becomes trapped between eggshell layers and persists until hatching. In contrast, the second polar body is internalized in a stereotyped manner by one of the anterior AB daughter cells around the 4-cell stage. Prior to internalization, actin and the phagocytic receptor CED-1 are enriched around the second polar body, consistent with formation of a phagocytic cup. CED-1 persists around the phagosome after internalization and is required for polar body internalization. Other CED-10-dependent engulfment pathway proteins, such as CED-2, are also

required, indicating that the polar body is internalized via receptor-mediated phagocytosis.

As part of a candidate screen, we also discovered that the second polar body was rarely internalized in PI3K-deficient *vps-34* mutants or in *rab-5* RNAi-treated embryos. The phagocytic receptor CED-1 is known to be localized to the plasma membrane via retromer-mediated recycling, which has been shown to require PI3K function. Furthermore, PI3K localization is known to depend on the small GTPase Rab5. Therefore, we examined CED-1 localization and discovered that CED-1 is no longer found around the second polar body in *vps-34* mutants and in *rab-5*-depleted embryos, explaining the observed defects in polar body internalization.

Thus, embryos internalize the second polar body via receptor-mediated phagocytosis, showing that the polar body signals to neighboring cells. This observation raises the possibility that polar bodies have a function after extrusion, which could indicate that polar body removal for genetic testing may not be non-invasive.

W401 X-specific targeting of the *C. elegans* dosage compensation complex. *Sevinc Ercan*, Sarah Albritton, Anna-Lena Kranz, Lara Winterkorn. New York University, New York, NY.

Sequence-specific transcription factors (TFs) bind to a small fraction of their sequence motifs in the genome. TF cooperativity and chromatin structure influence TF specificity. Here, we studied the factors that lead to X-chromosome specific targeting of a specialized condensin complex that constitutes the core of the *C. elegans* dosage compensation complex (DCC). Based on the ChIP-seq analysis of DCC recruiters, genomic distribution of the DCC recruitment DNA sequence motif, histone modifications and histone occupancy, we found that the DCC recruiter SDC-2 is required to open chromatin to allow DCC binding to clusters of motifs on the X chromosome. Thus, DNA sequence motif clustering and chromatin explain part of the specificity of DCC binding. However, motif and chromatin do not explain why some DCC recruitment sites with fewer motifs on the X are bound, and why some strong motif clusters on autosomes are not bound. To address this, we inserted different recruitment sites on the autosomes and tested their ability to recruit. Our results suggest a model in which long-distance cooperation between recruitment sites increase X-specificity of DCC recruitment. Extending this observation to other systems would imply a function for three-dimensional conformation of chromosomes in regulating specificity of protein targeting.

W402 Properties and activities of enhancers and promoters. *Chiara Cerrato*, Carson Woodbury, Eva Zeiser, Julie Ahringer. The Gurdon Institute, University of Cambridge, Cambridge, UK.

Gene expression is controlled through regulatory elements such as promoters and enhancers. Enhancers and other regulatory regions are usually bound by sequence-specific transcription factors that activate or repress transcription from promoters. The interactions, activities, and regulatory events that occur at and between enhancers and promoters are poorly understood.

We previously mapped the genome-wide landscape of RNA Polymerase II transcription initiation and elongation in *C. elegans* (Chen et al 2013). We identified ~75,000 sites of transcription initiation across the genome, most of which are bidirectional. In addition to transcription initiation sites at promoters, we also observed widespread bidirectional transcription initiation at enhancers. This pattern, which is also seen at mammalian enhancer regions, indicates a surprising similarity between enhancers and promoters.

We have been conducting transgenic assays to investigate and compare the activities of enhancers and promoters. We will present the results of these experiments, including findings showing that most tested core promoters contain extensive spatial and temporal information and that ~50% of tested enhancers can act as protein coding promoters, usually driving a subset of the associated gene's expression pattern.

W403 Quantitative analysis of context-dependent regulation by the Wnt pathway at single cell resolution. *J. I. Murray*, A. L. Zacharias, T. D. Lavon, E. Preston. University of Pennsylvania, Philadelphia, PA.

Signaling pathways achieve specificity in target gene activation through the dependence on additional inputs, commonly referred to as "context", such cell-specific transcription factors and appropriate chromatin states. To evaluate whether quantitative differences in activity of the Wnt pathway could also contribute to context-specific regulation, we measured the nuclear localization of the Wnt signaling pathway effectors, TCF and β-catenin, in all cells throughout development in *C. elegans* embryos. We found that the effect of Wnt compounds over successive exposures: we observed significantly increased nuclear localization of TCF and β-catenin in Wnt-signaled cells whose parents had also received a Wnt signal. This trans-generational "memory" of Wnt signaling influences target gene regulation suggesting that the level of signaling pathway activity can act an additional form of context.

To better understand how context information is encoded in Wnt target enhancers, we are investigating the dependence of enhancer activity on the organization and affinity of binding sites for TCF and other co-regulatory, cell-specific transcription factors. We identified 20 novel targets of the Wnt signaling pathway in *C. elegans* embryonic development, each expressed in a different subset of Wnt-signaled cells. We used modENCODE data and sequence conservation to identify 88 putative Wnt target enhancers and created a pipeline to test their activity in embryos. We image transgenic worms carrying fluorescent enhancer reporter constructs and a ubiquitously expressed GFP-histone at ~1 minute temporal resolution. Image analysis software identifies the nuclei and measures the reporter intensity, generating quantitative expression data for each individual cell at each timepoint from a single-celled zygote to a 600-cell elongating embryo, which we then compare with the expression of reporters driven by the full locus. Combining motif analysis of these enhancers with expression of candidate regulators from the EPIC database predicts specific regulators of each context-dependent enhancer, which we are currently testing experimentally.

W404 ShootingStar: Real-Time Tracking and Optical Manipulation of Single Cells in Development. *P. Shah*, A. Santella, Z. Bao. Memorial Sloan Kettering Cancer Center, New York, NY.

While *in toto* imaging and image analysis methods have advanced the study of multicellular phenomena in development at single-cell resolution, little progress has been made in the design of tools to perturb complex tissues with comparable spatial and temporal resolution.

Mutagenesis and RNAi are powerful tools for dissecting the genetic basis of developmental phenomena, yet neither offers the specificity or the temporal control required for dissecting the roles played by individual cells in coordinating developmental processes. Classical single cell perturbation techniques such as laser cell ablation and newer technologies built around photoactivatable reagents offer significant promise in filling this need. Their use to-date, however, remains limited by the challenge of reliably identifying target cells.

We have developed a platform for the real-time segmentation and tracking of single cells in 3D tissues to enable reproducible single cell perturbations at high throughput and without a need for cell-specific markers. ShootingStar can currently maintain real-time throughput on desktop hardware for C. *elegans* datasets until the onset of twitching and for D. *rerio* and D. *melanogaster* embryos containing on the order of thousands of cells. We have benchmarked this platform by the successive and parallel ablations of neural progenitors and neuronal support cells in the embryo of C. *elegans*. Specifically, we have performed parallel ablations of all 6 GLR cells to probe their role in nerve ring positioning. Ablated embryos exhibit no gross defects in nerve ring morphology or positioning but hatch late with the nerve ring exhibiting a strong anterior shift and evidence of defasciculation (N=3). While anatomical evidence has suggested that the GLR's play a role in nerve ring assembly, our observations instead suggest a role in maintaining nerve ring positioning during elongation and pharyngeal morphogenesis. While our applications to-date have focused on laser cell ablation, the architecture of ShootingStar allows for a diverse set of perturbations such as single-cell heatshock or the use of photoconvertible fluorophores to selectively label single cells on-demand. Current efforts are directed towards demonstrating these applications as well as the parallelization of cell tracking to enable real-time lineage tracing later in development for larger model organisms. The long-term goal of our work is to establish ShootingStar as a generalized platform for the study of single cell behaviors in complex multicellular environments *in vitro* and *in vivo*.

W405 Tissue-specific analysis of nuclear organization through development of a novel FLP/Frt-based toolkit for spatiotemporal control of gene expression. *P. Askjaer*, C. Muñoz-Jiménez, C. Ayuso, A. Dobrzynska, G. Gómez-Saldivar, L. Riquelme. CSIC-Uni Pablo de Olavide, Seville, ES.

The nuclear envelope (NE) plays critical roles in gene expression through controlling access to the nucleus, anchoring of chromosomes at the nuclear periphery and serving as platform for chromatin-interacting proteins, such as histone modifiers and transcription factors. Several human diseases are attributed to alterations in NE structure, including the laminopathies, whose name refers to underlying mutations in components of the nuclear lamina and lamina-associated proteins. One example is Emery-Dreifuss muscular dystrophy, which is caused by mutations in the inner nuclear membrane protein emerin or in lamin.

We recently found that emerin/EMR-1 is required for correct neuromuscular junction activity in *C. elegans*. Firstly, EMR-1 associates with genes involved in muscle and neuronal function and deletion of *emr-1* causes local changes in nuclear architecture. Secondly, transcriptome analyses revealed that EMR-1 is associated with gene repression, particularly of genes implicated in muscle and nervous system function. Thirdly we demonstrated that *emr-1* mutants are sensitive to the cholinesterase inhibitor aldicarb, indicating altered activity at neuromuscular junctions.

Although many NE proteins are ubiquitously expressed, laminopathies often affect a single tissue. This has led to the hypothesis that tissue-specific alterations in nuclear organization are responsible for particular clinical manifestations of laminopathies. Specifically, changes in interactions between NE proteins and chromatin are thought to be relevant, but has not been explored in intact organisms due to technical limitations. This triggered us to develop novel tools to dissect the function of EMR-1 in tissue-specific nuclear organization. Using an optimized FLP recombinase, we show specific and efficient activation of dual color reporters is selected tissues. Importantly, our system is based on single-copy FLP and Frt transgenes integrated into the genome by MosSCI to ensure reproducible expression and to facilitate crosses. Until now, the repertoire of cell types amenable to analysis includes striated and nonstriated muscles, intestine, M cell lineage, seam cell lineage, hypodermis, and neurons (pan-neuronal and specific neuronal subtypes). We have implemented our FLP/Frt system to perform tissue-specific DamID, which has provided EMR-1/chromatin interaction profiles for different cell types, but the tool kit can easily be adapted for spatiotemporal control of other transgenes, including fluorescent reporters, dominant alleles or suicide genes.

W406 Systematic engineering of a temperature-optimized Gal4/UAS system for transcriptional control of gene expression in *Caenorhabditis elegans*. *Jonathan Liu*[1,2], Han Wang[1,2], Shahla Gharib[1,2], Navin Pokala[3], Paul W. Sternberg[1,2]. 1) Division of Biology and Biological Engineering, California Institute of Technology, Pasadena, CA; 2) Howard Hughes Medical Institute, California Institute of Technology, Pasadena, CA; 3) Department of Life Sciences, New York Institute of Technology, Old Westbury, NY.

A critical tool for studying gene function is the ability to control gene expression in desired temporal and spatial patterns. The bipartite Gal4/UAS system from yeast has become a powerful tool for manipulating gene expression in many model organisms since its discovery. However, this system has not been shown to work in *C. elegans*. Here, we systematically compare the transcriptional efficacy of three major components of this system- the activation domain, UAS copy number, and DNA-binding domain, all in order to develop an optimized Gal4/UAS system for gene expression in *C. elegans*. Most importantly, we find that the performance of Gal4 is heavily dependent on temperature and performs poorly at 20°C or below. To combat this, we use evolutionary analysis to identify a well conserved Gal4 from the yeast *Saccharomyces kudriavzevii* whose optimal growth temperature is 23-24°C. This new Gal4 is stronger, capable of recapitulating endogenous promoter strength, and also displays temperature robustness across the 15-25°C range. Our optimized Gal4/UAS system is capable of driving expression in a variety of tissues; we go on to demonstrate tissue-specific rescue, as well as gain-of-function channelrhodopsin experiments in neurons. All together, this constitutes a fully functioning bipartite gene expression system to increase the rate and rigor of research in *C. elegans* biology.

W407 Longevity and its transgenerational inheritance is enabled by H3K9 methylation. *T. W. Lee*, A. E. Engstrom, D. J. Katz. Emory University, Atlanta, GA.

Longevity is a complex trait influenced by environmental, genetic, and epigenetic factors. WDR-5, a member of the COMPASS complex, methylates histone 3 at lysine 4 (H3K4). Previously, the Brunet lab has shown that *wdr-5* mutants are long-lived, and this longevity is inherited by wild-type descendants. We demonstrate that longevity in this background is a transgenerational phenotype that takes several generations to manifest after the loss of WDR-5. Consistent with the gradual appearance of longevity in *wdr-5* mutant populations, we see that lifespan correlates with levels of dimethylation of histone 3 at lysine 9 (H3K9me2), a mark associated with repressive chromatin. This result suggests that H3K9me2 may be inherited transgenerationally and confer longevity in *wdr-5* mutants. To examine this possibility, we mutated *met-2*, the methyltransferase required for all germline H3K9me2, in *wdr-5* mutants. We show that the extended lifespan of *wdr-5* mutants is dependent on *met-2*, further implicating H3K9me2 in the mechanism of longevity. Moreover, our finding that H3K9me2 is heritable indicates that it may also be involved in the inheritance of longevity in *wdr-5* mutants. To test this possibility, we deleted *met-2* in descendants of *wdr-5* mutants, and find that the loss of *met-2* abolishes the inheritance of longevity. Taken together, these data support a model in which H3K9me2 facilitates longevity and its epigenetic inheritance.

W408 CRISPR-mediated synthetic genetic analysis reveals genetic interactions among RNA binding proteins affecting fitness and lifespan. *Adam Norris*, Xicotencatl Gracida, John Calarco. Harvard University, Cambridge, MA.

Experiments in unicellular organisms such as yeast have revealed widespread synthetic genetic interactions between genes and demonstrated that systematic analysis of genetic interactions can be utilized to assign shared biological functions to genes. As such, the ability to broadly survey genetic interactions with knockout alleles in metazoans would be highly desirable. We recently developed such a system in *C. elegans* to perform CRISPR/Cas9-based synthetic genetic analysis (CRISPR-SGA) using null mutations in a multicellular organism for the first time. Homologous recombination-mediated repair of double-strand breaks triggered by CRISPR/Cas9 replaces a target gene with one of two heterologous GFP transgenes, allowing reporter fluorescence to be followed as a proxy for the gene deletion. This enables generation of large numbers of double mutants by simply crossing the compatible single mutant animals and identifying double mutants by fluorescence microscopy. We applied CRISPR-SGA to genetic interactions between RNA binding proteins. RNA binding proteins are critical mediators of post-transcriptional regulation, but the majority of metazoan RNA binding proteins have no known molecular function or phenotype. Moreover, RNA binding proteins often act combinatorially to control post-transcriptional regulation, suggesting that single RNA binding protein mutations may lead to subtle or no phenotypes due to genetic redundancy. We deleted 11 non-essential evolutionarily-conserved RNA binding proteins and generated all 55 possible double mutants. Mutants were tested with a quantitative assay that measures competitive fitness compared to wild-type over multiple generations. We identified a number of double mutants with substantially lower fitness than would be predicted based on the additive defects of the two single mutant fitness scores. Follow-up on one such synthetic fitness defect revealed severe lifespan reduction in *exc-7;mbl-1* strains, though neither single mutant has a substantial effect on lifespan. The defect appears to be a specific aging phenotype, because developmental viability is not affected and additional markers of organismal health do not begin to decline until adulthood. Current follow-up experiments include RNA-Seq on the mutants as they age to shed light on the targets of the two RNA binding proteins, and tissue-specific rescue to determine the relevant tissue for the phenotype. These experiments demonstrate a substantial degree of synthetic fitness defects among RNA binding proteins and reveal pairs of genes important for maintaining organismal physiology. Moreover, our CRISPR-SGA system should be broadly applicable to anyone interested in metazoan synthetic genetics.

W409 Investigating the role of microtubule minus-end proteins in noncentrosomal microtubule organization during epithelial development. *Taylor Skokan*, Claire Baumer, Jessica Feldman. Stanford University, Stanford, CA.

The microtubule cytoskeleton is spatially reorganized from the centrosomes to new subcellular sites during cell differentiation, a process accomplished by a reassignment of microtubule organizing center (MTOC) proteins and function. In the developing *C. elegans* intestine, all MTOC function is reassigned from the centrosomes to the future apical cell membrane during cell polarization; microtubules grow from and are anchored at the apical membrane. This MTOC reassignment occurs relatively rapidly and synchronously in all polarizing intestinal cells and so affords us a system in which to probe the mechanisms controlling the formation of these new non-centrosomal MTOCs at the onset of cell differentiation. We find that microtubule minus-end binding proteins NOCA-1, PTRN-1, Ninein-like protein (T04F8.6), and γ-tubulin small complex (γ-TuSC) proteins GIP-1/GCP3, GIP-2/GCP2, and TBG-1/γ-tubulin localize to the apical MTOC. To determine the requirement of these proteins in membrane MTOC formation, we are taking advantage of a tissue-specific protein degradation system (Armenti et al. 2014) to deplete endogenous GIP-1 exclusively in the developing intestine around the time of MTOC reassignment. Using this method, we have found that GIP-1 is not required for the apical localization of the apical polarity protein PAR-3; however, GIP-1 is required for normal apical localization of GIP-2 and TBG-1. Surprisingly, apical microtubules are present in GIP-1-depleted embryos, suggesting an alternative method for nucleation and/or localization of microtubules at these sites. In other tissues, it has previously been reported that ptrn-1 functions in parallel to γ-TuSC to generate non-centrosomal microtubules; however, we find apically localized microtubules after depletion of both GIP-1 and PTRN-1 in developing intestines, suggesting the existence of a third pathway. GIP-1 appears to be essential for normal mitosis in the developing intestine as has been reported in the early embryo; embryos depleted of intestinal GIP-1 have fewer intestinal nuclei as compared to control embryos, and these nuclei appear consistently enlarged. Together, these results demonstrate that apical GIP-1 localization is required for the polarization of γ-TuSCs in the developing intestine, but that additional pathways exist to establish an apical MTOC. Furthermore, centrosomal GIP-1 localization is required for normal spindle formation and mitosis. Further investigation is necessary to determine how γ-TuSC-independent microtubules are generated at the apical membrane, and whether this population of microtubules differs from those of control embryos in quantity and dynamics.

W410 Cytoskeletal elements function together to move larval P-cell nuclei through constricted spaces. *Courtney Bone*, Yu-Tai Chang, Natalie Cain, Shaun Murphy, Daniel Starr. University of California Davis, Davis, CA.

Nuclear migration is a critical aspect of many developmental and cellular processes including fertilization, cell polarization, and differentiation. Disruptions of the nuclear envelope migration machinery lead to a variety of diseases including Hutchinson-Gilford Progeria Syndrome, Emery-Dreifuss Muscular Dystrophy, cancer and autism. For nuclear migration to occur, a bridge termed the LINC complex (for linker of nucleoskeleton and cytoskeleton), forms across the nuclear envelope to connect nuclear lamins to microtubule motors. In *C. elegans*, the LINC complex utilized for moving nuclei consists of the KASH protein, UNC-83 in the outer nuclear membrane and the SUN protein UNC-84 in the inner nuclear membrane. We have previously shown that UNC-83 recruits microtubule motors to the surface of the nucleus and UNC-84 interacts with the lamin LMN-1 to disperse forces throughout the nucleus. P-cell nuclear migration occurs during mid L1. The P-cell nucleus is approximately 3-4 μm in diameter, but must migrate through a 150 nm space between the body wall muscle and the cuticle of the worm. We hypothesize that dramatic cytoskeletal and nucleoskeletal rearrangements are necessary for nuclear migration through constricted spaces. We are investigating the roles of the cytoskeleton and nucleoskeleton during this nuclear migration event by visualizing these components *in vivo*. We aim to characterize the interacting roles of microtubule and actin pathways, as well as identify the role of the nuclear lamina in P-cell nuclear migration. Our data suggest a role for dynein as the primary microtubule motor functioning to move nuclei during P cell nuclear migration, while kinesin plays a more minor role. This is opposite to the roles of kinesin and dynein in embryonic hypodermal nuclear migrations. Additionally, a genetic screen for enhancers of *unc-84* implicates the actin cytoskeleton in P-cell nuclear migration. We are therefore investigating the dynamics of the actin network in P-cell development by live cell imaging of tagged actin binding proteins. We hypothesize nuclear lamina breakdown is necessary for nuclear reorganization to squeeze into the constricted space and used CRISPR/Cas9 to make a functional, GFP-tagged LMN-1. Our working model postulates that the nuclear lamina is remodeled to allow nuclei to squeeze through tight spaces, dynein provides the major force for P-cell nuclear migration, and kinesin and actin cables within the cell assist in nuclear migration.

W411 Mitochondria localize to injured axons to support regeneration. *S. Han*, H. Baig, M. Hammarlund. Yale Univ, New Haven, CT.

Axon regeneration after nerve injury requires generation of injury signals, elaboration of a growth cone, and target-directed growth. Little is known about the role of mitochondria during axon regeneration. Here we use *in vivo* single-neuron analysis to investigate the relationship between nerve injury, mitochondrial localization, and axon regeneration. Mitochondria accumulate in injured axons, and axons that fail to increase mitochondria have poor regeneration. Experimental alterations to mitochondrial distribution or mitochondrial respiratory chain function result in corresponding changes to regeneration outcomes. Axonal mitochondria are specifically required for growth cone migration, identifying a key energy challenge for injured neurons. Finally, mitochondrial localization to the axon after injury is regulated in part by dual-leucine zipper kinase-1 (DLK-1), a conserved regulator of axon regeneration. These data identify regulation of axonal mitochondria as a new cell biological mechanism that helps determine the regenerative response of injured neurons.

W412 *C.elegans* as a model to study extracellular vesicle biology, dynamics and function. *Jyothi Shilpa Akella*[1*], Juan Wang[1], Malan Silva[1], Julie Maguire[1], David Hall[2], Maureen Barr[1]. 1) Dept. of Genetics, Rutgers University, Piscataway, NJ; 2) Center for C.elegans Anatomy, Albert Einstein College of Medicine, Bronx, NY.

Extracellular vesicles (EVs) are nano-sized packages released by cells that function in intercellular communication. Cilia are hair-like projections that play important roles in development and signaling. The cilium both releases and binds to EVs. EVs play a role in cell signaling in health and pathologies, and may carry beneficial or toxic cargo. A fundamental understanding of the biogenesis, release, uptake, and signaling of ciliary EVs is lacking. Here, we demonstrate the utility of the nematode *C.elegans* as a model to identify the molecules and mechanisms that play a role in EV biology and function.

A subset of the ciliated neurons of *C.elegans* release EVs containing select cargo into the environment. These cargo include the polycystins LOV-1 and PKD-2. *C.elegans* EVs regulate the mating behaviors in a cargo-dependent manner. Using a candidate gene approach combined with live imaging of mutants that express GFP-tagged EV cargo, we are determining mechanisms driving biogenesis and release. Defects in the release of GFP-tagged EV cargo from the tips of EV releasing neurons (EVNs) and/or the accumulation of GFP-tagged EV cargo at the base of the EVNs indicates defects in EV biogenesis and/or release. We then use Transmission Electron Microscopy to determine whether the gene is required for EV biogenesis or EV release. Using these approaches, we have uncovered a requirement for cilia, the intraflagellar transport (IFT) machinery, a ciliary kinesin KLP-6, a stress-activated p38 MAPK PMK-1, and a novel myristoylated protein CIL-7. We are now determining whether a RAB protein and a phospholipid flippase play a role in ciliary EV biology. Thus, *C.elegans* can be used to study the relationship between cilia and EVs, and also identify the factors that regulate EV composition and function in health and disease.

Future studies are aimed at the identification of EV cargo, environmental conditions, and the components that regulate the biogenesis and release of EVs containing distinct cargoes.

W413 The TspanC8 tetraspanins TSP-12 and TSP-14 function through the ADAM10 protease SUP-17 to promote BMP signaling in *C. elegans*. *Lin Wang*, Zhiyu Liu, Herong Shi, Jun Liu. Cornell University, Ithaca, NY.

Bone morphogenetic proteins (BMPs) belong to the transforming growth factor β (TGFβ) superfamily of ligands. Malfunction of the pathway in humans can cause various developmental or physiological disorders. Thus it is critical that the BMP pathway is tightly regulated. Our lab has developed a sensitive and specific genetic screen in *C. elegans* to identify novel components that function to modulate BMP signaling (Liu et al., 2015). Using this screen, we have recently identified two evolutionarily conserved tetraspanins, TSP-12 and TSP-14, and an ADAM (a disintegrin

and metalloprotease) protease SUP-17, that function in promoting BMP signaling. TSP-12 and TSP-14 are paralogs that belong to the TspanC8 subfamily of tetraspanins, while SUP-17 is the ortholog of ADAM10. We have found that TSP-12 and TSP-14 function redundantly through SUP-17 to promote BMP signaling. All three proteins are expressed, and function, in the BMP receptor-expressing cells to modulate pathway activity. Both TSP-12 and TSP-14 can bind SUP-17 in a membrane-based yeast two-hybrid system, and are required for the cell surface localization of SUP-17. SUP-17/ADAM10 is known to cleave cell surface proteins through a process called 'ectodomain shedding'. One of the best known substrates of SUP-17/ADAM10 is Notch. We have found that the function of TSP-12, TSP-14 and SUP-17 in BMP signaling is independent of Notch signaling. We further provide genetic evidence that the neogenin homolog UNC-40, another positive modulator of BMP signaling (Tian et al., 2013), is one substrate of SUP-17/ADAM10. TSP-12, TSP-14, SUP-17 and UNC-40 are all conserved in mammals. We are currently determining whether their roles in BMP signaling are also conserved in mammals.

*The first two authors contributed equally to this work.

W414 Conserved NEKL/MLT protein network controls molting in *C. elegans*. *V. Lazetic*, J. Yochem, E. Karina, D. Fay. University of Wyoming, Laramie, WY.

Molting in *C. elegans* is essential for larval growth and development and involves remodeling of the apical extracellular matrix of the epidermis (cuticle) through cycles of degradation and re-synthesis. Using a genetic approach, we identified two NIMA family serine/threonine kinases, NEKL-2 and NEKL-3, and three ankyrin-repeat proteins (MLT-2, MLT-3, and MLT-4), as essential for the completion of molting. Furthermore, genetic analyses indicate that *nekl-2* and *nekl-3* carry out partially redundant functions. NEKL-3 is highly conserved and very similar to mammalian Nek6 and Nek7, which regulate several cell cycle processes involving microtubules. Co-expression of mammalian Nek6 and Nek7 rescue molting defects in *nekl-3* mutants, suggesting that these proteins share a conserved molecular function. Surprisingly, *nekl-3* is not required for cell cycle regulation in *C. elegans*, but functions specifically in the epidermis to promote cuticle shedding, possibly through the regulation of cytoskeleton architecture, vesicular trafficking, or both. NEKL-2 is the most similar to mammalian Nek8, which may control microtubule organization during the formation of primary cilia. NEKL-2 functions specifically in the epidermis, a tissue lacking cilia, where it promotes the endocytosis of LRP-1/megalin, an essential molting factor and receptor for low-density lipoproteins. Furthermore, NEKL-2 functions as global regulator of clathrin-mediated endocytosis in the epidermis. Our data, together with studies of their mammalian orthologs, indicate that NEKL-2 and NEKL-3 associate with ankyrin-repeat proteins, which may function as scaffolds for NEKL-2 and NEKL-3 signaling. Loss of several conserved ankyrin-rich proteins (MLT-2/ANKS6, MLT-3/ANKS3 and MLT-4/INVS) leads to specific defects in molting similar to *nekl-2* and *nekl-3* mutants, and also show defects in LRP-1 trafficking. CRISRP-generated fluorescently labeled NEKL-2, MLT-2 and MLT-4 largely colocalize with each other in the main epidermal tissue of *C. elegans*. Correspondingly, NEKL-3 and MLT-3 show similar expression patterns and Y2H analysis indicates that NEKL-3 and MLT-3 physically interact. This interaction is important for the proper localization of NEKL-3 in the cytosol, as *mlt-3* depletion leads to abnormal nuclear accumulation of NEKL-3. Interestingly, *nekl-3*, *nekl-2* and *mlt-4* defects are partially suppressed by *cdc-42* depletion, suggesting that CDC-42 could be a target for negative regulation by the NEKL–MLT network, which may regulate trafficking and/or cytoskeletal organization during molting cycles. Taken together, our studies have identified several unique roles for NIMA family kinases that we expect are conserved in other eukaryotes, including mammals, but which have been largely overlooked.

W415 The catalytic activity of twitchin's kinase domain inhibits muscle activity. *Guy Benian*[1], Yohei Matsunaga[1], Hyundoo Hwang[2], Rhys Williams[3], McKenna Penley[1], Hiroshi Qadota[1], Levi Morran[1], Hang Lu[2], Olga Mayans[3]. 1) Emory Univ, Atlanta, GA; 2) Georgia Institute of Technology, Atlanta, GA; 3) University of Konstanz, Germany.

Sarcomeres, the fundamental unit of muscle contraction, contain giant polypeptides (>700,000 Da) consisting of multiple immunoglobulin and fibronectin type 3 domains, one or two protein kinase domains, and in some cases, highly elastic regions. *C. elegans* has 3 such proteins; twitchin (encoded by *unc-22*), UNC-89 and TTN-1. The function, substrates and mechanism of activation of the kinase domains of these giant proteins are unknown. *unc-22* mutants display "twitching" of the animal's surface, ~1-2 times/s, which originates from the underlying muscle, and also, to varying extents, reduced locomotion and disorganized sarcomeres. We wondered how the kinase domain of twitchin contributes to this phenotype. We converted a highly conserved lysine (K) involved in ATP binding to alanine (A) and showed that this abolishes the kinase activity of recombinant twitchin kinase in vitro towards an artificial substrate. The behavior of the KtoA mutated protein is very similar to that of the wild type protein; crystals have been grown and we plan to obtain a structure and compare it to the published wildtype structure. We used CRISPR/Cas9 to introduce the same mutation in the endogenous *unc-22* gene, resulting in expression of a kinase-dead twitchin. This mutant does not twitch, and shows normal sarcomeric structure by immunostaining using a battery of antibodies to sarcomeric proteins. Remarkably, however, a thrashing assay in liquid reveals that *unc-22(KtoA)* moves ~25% faster than wild type. While crawling on an agar surface *unc-22(KtoA)* has a ~60% greater velocity than wildtype. Using an optogenetic method, the KtoA mutant shows an abnormal pattern with more overall contraction, and faster rates of contraction and of relaxation. Thus, twitchin kinase activity is required to inhibit the contraction/relaxation cycle. The closest homolog of twitchin in vertebrates is titin, but titin's kinase domain is an inactive pseudokinase. Twitchin kinase from Aplysia is also active, as is the kinase domain from the twitchin homolog in Drosophila called projectin. We wondered if there was a selective advantage in maintaining kinase activity. To test this hypothesis in *C. elegans*, we conducted a competitive fitness assay; competing either wild type individuals or *unc-22(KtoA)* mutants against a GFP-marked tester strain. After 4 generations, the wildtype strain

exhibited significantly greater fitness than the *unc-22(KtoA)* strain. Specifically the wildtype strain increased in frequency ~17% relative to the tester strain, while the *unc-22(KtoA)* strain decreased ~20% in frequency over 4 generations. Thus, there is a substantial selective advantage in maintaining the kinase activity of twitchin.

W416 Modeling cerebral cavernous malformations in *C. elegans*. *Brent Derry*, Swati Pal. Hospital for Sick Children, Toronto, ON, CA.

Cerebral Cavernous Malformations (CCM) are vascular disorders of central nervous system that arise from weakened blood capillaries causing blood leakage. Three genes have been shown to cause familial CCM in humans, *CCM1*, *CCM2* and *CCM3*, and two are conserved in the worm (*kri-1*/*CCM1* and *ccm-3*/*CCM3*). Patients with mutations in *CCM3* have a earlier disease onset and a more severe prognosis than *CCM1* or *CCM2* patients. CCM1-3 form a ternary complex but CCM-3 protein resides predominantly in the STriatin Interacting Phosphatase and Kinase (STRIPAK) complex in cells. We previously showed that *kri-1* is required in the soma to promote DNA damage-induced germline apoptosis (Ito *et al*., 2010) whereas *ccm-3* is required for excretory canal extension (Lant *et al*., 2015), demonstrating distinct cellular functions for these genes. Using the germline as a model we show that CCM-3/STRIPAK is also required for rachis development by regulating both endocytic recycling and the anctinomysin cytoskeleton.

During development germ cells undergo incomplete cytokinesis to create openings into a common lumen (rachis), which requires the coordinated activity of cytoskeletal proteins and receptor-mediated signalling pathways, such as Notch and Ras/MAPK. *ccm-3* mutants have fewer mitotically proliferating germ cells and reduced GLP-1/Notch. Since we previously showed that *ccm-3* mutants are defective in endocytic recycling we asked if mitotic cell proliferation could be restored by inhibiting *sel-9,* which negatively regulates transport of GLP-1 to the membrane surface. Indeed, *sel-9(RNAi)* restored mitotic cell proliferation in *ccm-3* mutants to wild type levels. We also observed diminished Ras/MAPK signalling and failure to present the vitellogenin receptor RME-2 on oocytes, suggesting a general defect in endocytic recycling. Consistent with this, we found that CCM-3 colocalizes with the endosome recycling protein RAB-11.

Loss of anillin proteins results in germline defects that are strikingly similar to *ccm-3* mutants, suggesting potential interactions between these scaffolding proteins in promoting rachis development. CCM-3 and its binding partner GCK-1 are required for cortical localization of ANI-1 and the non-muscle myosin NMY-2. Knockdown of *ccm-3* also results in defective mitotic division and loss of polarity proteins in the germline and embryo. Based on these results we propose that CCM-3 functions to couple vesicle trafficking and acto-myosin organization in order to fine-tune membrane patterning and polarity in the germline and embryo. Using *C. elegans* to understand the CCM-3 regulatory network should help identify non-surgical therapies for treating CCM patients, which we are pursuing also through small molecule screens.

W417 A regulatory map of the C.elegans nervous system. *Oliver Hobert*. Columbia University, New York, NY.

W418 Single-cell *C. elegans* transcriptomics: Deciphering the expression of all genes in all cells throughout development. *I. Yanai*[1,2], T. Hashimshony[2], A. Cole[2]. 1) New York University, New York City, NY; 2) Faculty of Biology, Technion, Israel.

To understand embryogenesis, it is crucial to elucidate the expression state of each gene in every cell of the organism. This is not feasible at present for most organisms, yet it is conceivable for the nematode *C. elegans* given that only 1,304 cells occur by the first larval stage. Over thirty years ago, the full cell lineage of *C. elegans* was deciphered through the pioneering work of John Sulston. While this work defined the ancestry and fate of each cell, the overall underlying gene regulatory networks remain unknown. To assist in this challenge, we previously pioneered a multiplexed single-cell RNA-Seq method called CEL-Seq. Here, we invoke CEL-Seq to define the transcriptome of each cell throughout *C. elegans* embryogenesis. We collected and processed over two thousand cells from fifty embryos spanning the fertilized egg to the penultimate cell division. We found that cells generally cluster according to their stage and lineage. To decipher the exact identity of each cell we made use of the wealth of previously defined tissue-specific gene expression. The resulting database of gene expression in virtually all cells is a tremendous resource that will be important for developmental biologists, systems biologists, and computational biologists alike. We used the data to explore the general questions of how a cell produces progeny of distinct fates, and how different cells reach the same fate. For this we characterized cell-fate specification at single-cell resolution and report the patterns of similarity in differences for muscle and pharyngeal cells produced by different founder-cell lineages. Our work renders *C. elegans* the first organism for which the states of all genes are known throughout embryogenesis. While this has been a major undertaking for us, we expect our approach to be routinely adopted for the study of different species and genetic perturbations to further illuminate embryogenesis.

W419 A combined binary interaction and phenotypic map of *C. elegans* cell polarity proteins. *Mike Boxem*[1*], Diana Klompstra[2,3], Monique van der Voet[1], Irma Lemmens[4,5], João Ramalho[1], Susan Nieuwenhuize[1], Sander van den Heuvel[1], Jan Tavernier[4,5], Jeremy Nance[2,3], Thijs Koorman[1]. 1) Division of Developmental Biology, Department of Biology, Faculty of Science, Utrecht University, 3584 CH, Utrecht, The Netherlands; 2) Helen L. and Martin S. Kimmel Center for Biology and Medicine at the Skirball Institute of Biomolecular Medicine, NYU School of Medicine, New York, New York 10016, USA; 3) Department of Cell Biology, NYU School of Medicine, New York, New York 10016, USA; 4) 4Department of Medical Protein Research, VIB, 9000 Ghent, Belgium; 5) 5Department of Biochemistry, Faculty of Medicine and Health Sciences, Ghent University, 9000 Ghent, Belgium.

The ability to polarize is a fundamental cellular property, required for processes such as cell migration and asymmetric cell division, and for the specification of functionally distinct domains. Several key determinants of cell polarity have been identified, including the Par, Crumbs, and Scribble groups of cortical polarity regulators. However, we know comparatively little of the mechanisms through which cortical polarity is integrated with cellular events such as cytoskeletal rearrangement, organization of a polarized trafficking machinery, and functional specialization of membrane domains. A full understanding of polarity establishment will require a comprehensive knowledge of the proteins

involved in this process and the molecular interactions between them.

Here, we study the network of physical interactions that underlies polarity establishment in the nematode *Caenorhabditis elegans* using a combination of large-scale yeast two-hybrid screens and phenotypic profiling. Using a fragment-based yeast two-hybrid strategy, we identified 439 interactions between 296 proteins, as well as the protein regions that mediate these interactions. Phenotypic profiling of the network resulted in the identification of 100 physically interacting protein pairs for which RNAi-mediated depletion caused a defect in the same polarity-related process. We demonstrate the predictive capabilities of the network by showing that the physical interaction between the RhoGAP PAC-1 and PAR-6 is required for radial polarization of the *C. elegans* embryo. Our network represents a valuable resource of candidate interactions that can be used to further our insight into cell polarization.

W420 Caenorhabditis Genetics Center (CGC). *Aric Daul*, Theresa Stiernagle, Julie Knott, Kemi Awoyinka, Ann E. Rougvie. CGC, Univ of Minnesota, Minneapolis, MN.

The Caenorhabditis Genetics Center (CGC) is supported by the National Institutes of Health - Office of Research Infrastructure Programs (NIH-ORIP) and housed at the University of Minnesota. Our primary aim is to acquire, curate, and maintain Caenorhabditis strains and distribute them upon request to researchers throughout the world. There are now nearly 20,000 different strains in the collection, including more than two thousand whole-genome sequenced strains obtained from the Million Mutation Project and other sources. We strive to have at least one allele of every published gene and all chromosome rearrangements, duplications and deficiencies. Selected multiple-mutant stocks and transgenic strains are also available, such as strains that express various fluorescent protein reporter fusions. The CGC has initiated a small research component aimed at enhancing the genetic tool kit available to *C. elegans* researchers, including labeling balancer chromosomes with fluorescent markers (some of which are now available). The CGC also distributes stocks of nematode species closely related to *C. elegans* and bacterial strains necessary for nematode growth. A searchable list of strains, including information about CGC stocks, is accessible through the CGC website (http://cbs.umn.edu/cgc/home) and WormBase (http://www.wormbase.org). Requests for strains should be made on-line through our website. Follow us on Twitter **@cgc_worms** for updates on new strains and other news.

As mandated by NIH-ORIP, a small yearly user fee and charge per strain is assessed with each order. The CGC strongly encourages use of credit cards for payments. We provide yearly reports to the NIH with statistics that reflect our services to the worm community. A key tracked parameter is the number of published papers that acknowledge the CGC for providing strains. **Please remember to acknowledge the CGC in your publications!**

W421 Genetic Background and Experimental Reproducibility Play Critical Roles in Identifying Chemical Compounds with Robust Positive Effects on Longevity. *Mark Lucanic*[1], Max Guo[2], Gordon Lithgow[1], Monica Driscoll[3], Patrick Phillips[4], Caenorhabditis Intervention Testing Program. 1) Buck Institute for Research on Aging, Novato, CA; 2) Division of Aging Biology, National Institute on Aging, 7201 Wisconsin Avenue, Bethesda, MD; 3) Rutgers University, Dept. of Molecular Biology and Biochemistry, Nelson Biological Laboratories, Piscataway, NJ; 4) Institute of Ecology and Evolution, University of Oregon, Eugene, OR.

Defining approaches that limit the debilitating consequences of aging is a major challenge of our time. One approach toward improving mid- and later life health focuses on pharmacological interventions that optimize healthy aging across a diverse population. The *Caenorhabditis elegans* Intervention Testing Program (CITP) formed to study the effects of promising chemicals across diverse genetic backgrounds as a means to identify robust candidates likely to target conserved processes. To test the reproducibility of these lifespan studies, we assessed longevity in 22 *Caenorhabditis* nematode natural isolates spanning 3 species with multiple biological replicates across 3 laboratories. Although our analyses attributed virtually no variation among the locations, at each site ~10% of observed variation was associated with individual trials, with *C. briggsae* isolates in particular displaying large variations from trial-to-trial. We next tested 10 chemicals previously reported to affect longevity across a genetically diverse subset of these strains. We found that the reported dietary restriction mimetics in our set of chemicals promoted longevity in the *C. elegans* strains, but as a group exhibited inconsistent effects across the other *Caenorhabditis* strains. In contrast, the common laboratory dye ThioflavinT showed generally potent and robust positive effects on lifespan across the *Caenorhabditis* genus. Our survival analysis results indicated that assessment of genetic and experimental sources of variation is important for the identification of compounds with robust effects on longevity. Our results further highlight specific chemicals that warrant further exploration as potential leads for pharmacological interventions that can improve health in aging animals.

W422 The neuroendocrine peptide DAF-7/TGF-β is a key regulator of dietary restriction in *C. elegans*. *M. Fletcher*, D. Kim. MIT, Cambridge, MA.

The neuromodulator DAF-7/TGF-β is a key regulator of *C. elegans* physiology and behavior. DAF-7 is expressed in and secreted from chemosensory neurons and expression levels have been shown to be sensitive to environmental factors such as food availability and pheromone concentration. Signaling through DAF-7 regulates dauer formation and fat metabolism, as well as a number of diverse behaviors. Additionally, *daf-7* mutations have been observed to extend lifespan in a *daf-16* dependent manner. Here, we show that response to dietary restriction (DR), a treatment that extends lifespan, is also dependent on *daf-7*. We further investigate the dynamics of *daf-7* expression throughout the aging process of *C. elegans* to characterize how this signaling pathway acts to modulate lifespan and allow *C. elegans* to respond to changes in nutritional availability to promote longevity under dietary restriction. Understanding how limited nutritional resources elicit a response in this particular neuroendocrine pathway to confer lifespan benefits may allow us to gain insight into how DR may be acting to delay the aging process across species.

W423 *dbl-1*/TGF-β and *daf-12*/NHR signaling mediate cell-nonautonomous effects of *daf-16*/FOXO on starvation-induced developmental arrest. *R. E. W. Kaplan*, Y. Chen, B. T. Moore, J. M. Jordan, C. S. Maxwell, A. J. Schindler, L. R. Baugh. Duke University, Durham, NC.

Nutrient availability has profound influence on development. In the nematode *C. elegans,* nutrient availability governs post-embryonic development. L1-stage larvae remain in a state of developmental arrest after hatching until they feed. This “L1 arrest” (or "L1 diapause") is associated with increased stress resistance, supporting starvation survival. Loss of the transcription factor *daf-16*/FOXO, an effector of insulin/IGF signaling, results in arrest-defective and starvation-sensitive phenotypes. We show that *daf-16*/FOXO regulates L1 arrest cell-nonautonomously, suggesting that insulin/IGF signaling regulates at least one additional signaling pathway. We used mRNA-seq to identify candidate signaling molecules affected by *daf-16*/FOXO during L1 arrest. *dbl-1*/TGF-β, a ligand for the Sma/Mab pathway, *daf-12*/NHR and *daf-36*/oxygenase, an upstream component of the *daf-12* steroid hormone signaling pathway, were up-regulated during L1 arrest in a *daf-16*/FOXO mutant. Using genetic epistasis analysis, we show that *dbl-1*/TGF-β and *daf-12*/NHR steroid hormone signaling pathways are required for the *daf-16*/FOXO arrest-defective phenotype, suggesting that *daf-16*/FOXO represses *dbl-1*/TGF-β, *daf-12*/NHR and *daf-36*/oxygenase. The *dbl-1*/TGF-β and *daf-12*/NHR pathways have not previously been shown to affect L1 development, but we found that disruption of these pathways delayed L1 development in fed larvae, consistent with these pathways promoting development in starved *daf-16*/FOXO mutants. Though the *dbl-1*/TGF-β and *daf-12*/NHR pathways are epistatic to *daf-16*/FOXO for the arrest-defective phenotype, disruption of these pathways does not suppress starvation sensitivity of *daf-16*/FOXO mutants. This observation uncouples starvation survival from developmental arrest, indicating that DAF-16/FOXO targets distinct effectors for each phenotype and revealing that inappropriate development during starvation does not cause the early demise of *daf-16*/FOXO mutants. Overall, this study shows that *daf-16*/FOXO promotes developmental arrest cell-nonautonomously by repressing pathways that promote larval development.

W424 Fasting protects against proteostasis defects induced by hypoxia. *N. Iranon*, D. Miller. University of Washington, Seattle, WA.

Oxygen plays a critical role in aerobic metabolism. Accordingly, low oxygen conditions (hypoxia) can impair essential physiological processes and cause cellular damage and death, such as is observed as a result of stroke and cardiovascular disease. However, hypoxic preconditioning, in which a non-injurious hypoxic exposure precedes the damaging hypoxic insult, has been shown to be effective at attenuating the cellular damage caused by hypoxia, suggesting that there are cellular mechanisms that can protect against hypoxic damage. We have found that specific concentrations of hypoxia cause a disruption of protein homeostasis in *C. elegans*, as measured by increased aggregation of polyglutamine proteins in the body wall muscles. Here, we show that nutritional cues regulate the effect of hypoxia on proteostasis. Animals that are fasted develop dramatically fewer protein aggregates compared to their fed counterparts when exposed to hypoxia. Polyglutamine and amyloid-beta protein aggregation in the body wall muscles is thought to be cytotoxic, resulting in age-dependent uncoordination and eventual paralysis. In support of this, fed animals exposed to hypoxia have an accelerated rate of paralysis compared to controls maintained in room air. However, animals that are fasted prior to hypoxia are partially rescued from this expedited paralysis rate. We also demonstrate that fasted animals are resistant to the long-term effects of hypoxia on proteostasis. When animals are exposed to hypoxia for a short period of time, they do not display increased polyglutamine aggregation. Yet, as the animals continue to grow and develop in room air, the appearance of aggregates is accelerated in fed animals exposed to hypoxia, whereas fasted animals accumulate aggregates at a rate identical to room air controls. Taken together, our results underscore the influential role of nutritional state on both the immediate and long-term effects of hypoxia on proteostasis.

W425 Omega-3 and -6 fatty acids allocate somatic and germline lipids to ensure fitness during nutrient and oxidative stress in *Caenorhabditis elegans*. *Sean Curran*, Dana Lynn. University of Southern California, Los Angeles, CA.

Animals in nature are continually challenged by periods of feast and famine as resources inevitably fluctuate, and must allocate somatic reserves for reproduction to abate evolutionary pressures. We identify an age-dependent lipid homeostasis pathway in *Caenorhabditis elegans* that regulates the mobilization of lipids from the soma to the germline, which supports fecundity but at the cost of survival in nutrient-poor and oxidative stress environments. This trade-off is responsive to the levels of dietary carbohydrates and organismal oleic acid and is coupled to activation of the cytoprotective transcription factor SKN-1 in both laboratory-derived and natural isolates of *C. elegans*. The homeostatic balance of lipid stores between the somatic and germ cells is mediated by arachidonic acid (omega-6) and eicosapentaenoic acid (omega-3) precursors of eicosanoid signaling molecules. Our results describe a mechanism for resource reallocation within intact animals that influences reproductive fitness at the cost of somatic resilience.

W426 RAB-35 coordinates the engulfment and degradation of apoptotic cell corpses. *R. C. Haley*, Ying Wang, Zheng Zhou. Baylor College of Medicine, Houston, TX.

In metazoan organisms, apoptotic cells are swiftly engulfed by phagocytes and degraded inside phagosomes through phagosome maturation. Defects in this process can cause inflammatory responses and autoimmune diseases. In the nematode *C. elegans*, a number of proteins that control the recognition, engulfment, and degradation of apoptotic cells have been identified. In particular, small GTPases known as Rabs, well known for their role in vesicle trafficking, have been implicated in the maturation of developing phagosomes and the degradation of apoptotic cell corpses. To systematically identify all the RAB proteins that play roles in apoptotic cell clearance, we performed an RNAi screen targeting 29 RAB-encoding genes in the *C. elegans* genome, searching for the presence of extra cell corpses in worm embryos. In addition to *rab-2*, *rab-5*, and *rab-7*, which were previously known to function in phagosome maturation, we discovered that inactivation of *rab-35* also results in the *ced* (cell death abnormal) phenotype indicative of defects in apoptotic cell clearance. RAB-35 is an oncogene that has been implicated in a number of cellular processes such as the termination of cytokinesis and the control of the PI3K/AKT growth pathway. We have observed that RAB-35 localizes to the nascent phagosome in a biphasic manner around the time of phagosomal sealing. Subsequent

experiments revealed that a *rab-35* loss-of-function causes defects in both the engulfment and subsequent degradation of cell corpses. Moreover, genetic tests indicated that *rab-35* acts upstream of *rab-7* and may represent a novel cell-corpse removal pathway. We are investigating the molecular function of RAB-35 in this pathway, in particular the functional relationship between RAB-35 and the lipid second messengers PtdIns(4,5)P_2 and PtdIns(3)P.

W427 Hemicentin regulates Anillin to promote cytokinesis in *Caenorhabditis elegans* germ cells. *YC. Tse*, J. Wu, L. Zeng. Southern University of Science and Technology, Shenzhen, CN.

The success of cell division to equally segregate genetic materials into two daughter cells depends on the constriction of actomyosin-based contractile ring. The spatial and temporal regulation of contractile ring at the division plane primarily depends on two parallel intracellular signals, centralspindlin-dependent and astral relaxation pathways, in which both of them are studied extensively. However, the extracellular signal that regulates cytokinetic processes is poorly investigated. Up to now, only hemicentin (HIM-4), an extracellular matrix protein, has been showed may regulate cytokinesis in mouse embryos and *C. elegans* germline. Depletion of HIM-4 in both model organisms leads to multinucleated cells. However, the molecular mechanism of HIM-4 in cytokinesis regulation is still not clear. In this study, we demonstrate that HIM-4 is recruited to the site of cleavage furrow and promotes proper cytokinesis in *C. elegans* germ cell. The timing of contractile ring formation and cleavage furrow closure is greatly delayed in HIM-4-depleted germ cells. In addition, the recruitment and dynamic of ANI-1 is reduced in HIM-4-depleted gonad, while non-muscle myosin (NMY-2) and ANI-2 remain unchanged. Collectively, our data suggest that HIM-4 may regulate cytokinesis by promoting and stabilizing ANI-1 to the site of division in *C. elegans* germ cells.

W428 ATX-2, The *C. elegans* Ortholog of Human Ataxin-2, Regulates Centrosome Size and Microtubule Dynamics. *Michael Stubenvoll*, Jeff Medley, Mi Hye Song. Oakland University, Rochester, MI.

Centrosomes are critical sites for orchestrating microtubule behavior and exhibit dynamic changes in size during the cell cycle. As cell cycle progresses to mitosis, centrosomes recruit more microtubules to form bipolar spindles that ensure accurate chromosome segregation. The *szy-20* gene encodes a conserved RNA-binding protein that negatively regulates centrosome duplication by opposing ZYG-1, a key centrosome duplication factor. Centrosomes in *szy-20* mutants exhibit elevated levels of centrosomal proteins, resulting in defective microtubule dynamics and embryonic lethality. SZY-20 contains putative RNA-binding domains (SUZ, SUZ-C): mutating these domains has been shown to perturb *in vitro* RNA-binding of SZY-20 and its capacity to regulate centrosome size *in vivo*. Despite the finding that SZY-20 negatively regulates ZYG-1, no direct interaction between the two proteins has been found. Thus, identifying additional factors that function between SZY-20 and ZYG-1 should provide further insights into the molecular mechanism by which the RNA-binding protein SZY-20 influences centrosome assembly.

Toward this end, we identified an RNA-binding protein, ATX-2, that physically associates with SZY-20. ATX-2 is the *C. elegans* ortholog of human Ataxin-2 that is implicated in human neurodegenerative disease. We show a new role for ATX-2 in regulating centrosome size and microtubule dynamics. Depletion of ATX-2 results in embryonic lethality and cytokinesis failure in wild type embryos, and restores centrosome duplication to *zyg-1*mutants. ATX-2 forms a complex with SZY-20 in an RNA-independent fashion. In this pathway, SZY-20 promotes ATX-2 abundance, which inversely correlates with centrosome size. Centrosomes in *atx-2* mutants exhibit elevated levels of centrosome factors (ZYG-1, SPD-5, γ-Tubulin), increasing microtubule nucleating activity but hindering microtubule growth. We show that ATX-2 influences microtubule behavior by regulating the microtubule nucleating factor γ-Tubulin and microtubule destabilizer KLP-7. Our data suggest that RNA-binding proteins play an active role in controlling microtubule dynamics and provide insight into the control of proper centrosome size and microtubule behavior.

W429 Developing quantitative resource for computational analysis from images of *C. elegans* embryogenesis in a public database Phenobank. *Y. Tohsato*, H. Okada, J. Takayama, K. Kyoda, S. Onami. RIKEN Quantitative Biology Center, Kobe, Japan.

Along with the recent popularization of live-imaging technologies, various types of microscopy images are becoming available in public databases. Quantitative data such as positions and shapes of nuclei and cells, and their temporal changes obtained from these images are important resources for understanding biological phenomena as dynamical systems. Such resources can be used in various kinds of computational analysis including phenotype screening and mathematical modeling. Here, we develop a new resource of quantitative data on nuclear division dynamics in *C. elegans* RNAi-treated embryos. Quantitative data were extracted from two-dimensional time-lapse differential interference contrast microscopy images in a public database, Phenobank, using our newly developed automated image processing system. They consist of 1,579 datasets of quantitative data for RNAi-treated embryos. These datasets include three sets of data for each of the genes (i.e. 518/549 of all genes) that exerted defects in embryogenesis without inducing F0 sterility when depleted individually by RNAi. Each data contains the outlines of nuclear regions and their temporal changes. All data were verified through manual error correction, and annotated with cell name and anterior-posterior axis. To demonstrate the usage of such resource, we applied it to computational phenotype screening on female pronuclear migration. In this screening, fifteen candidate genes were selected for faster or slower migration by calculating the maximum migration speed. Seven out of the fifteen genes were confirmed to reproduce each of the phenotype in our independent experiments. Among them, *sds-22* and *F44B9.8* exhibited significantly faster and slower migration respectively than wild-type. *sds-22*(RNAi) and *F44B9.8*(RNAi) embryos expressing GFP::tubulin exhibited markedly larger and smaller asters respectively, consistent with the nuclear tracking along microtubules mechanism. This resource will be openly available in SSBD database (http://ssbd.qbic.riken.jp).

W430 PAR polarity proteins promote enhanced spindle assembly checkpoint activity in germline blastomeres. *A. R. Gerhold*[1], P. S. Maddox[2], J.-C. Labbé[1]. 1) University of Montréal, Montréal, Québec, CA; 2) University of North Carolina, Chapel Hill Chapel Hill, NC.

The spindle assembly checkpoint (SAC) is a fundamental mitotic regulator that maintains genome stability by ensuring the fidelity of

chromosome segregation. Defects in SAC surveillance can lead to aneuploidy, while several major chemotherapeutics (e.g. Taxol) rely on SAC-mediated mitotic arrest. The strength of the SAC varies between cell types and organisms, yet the reason for these differences is poorly understood. We have recently characterized SAC activity in C. elegans germline stem and progenitor cells (GSPCs) using *in situ* live-imaging of GSPC mitosis in whole-mount animals. Our work indicates that the SAC is stronger in GSPCs than in early embryonic blastomeres, providing a platform to dissect how SAC activity can vary between cell types and to uncover stem cell-specific adaptations. GSPCs are derived from an embryonic germline founder cell that is specified by a series of asymmetric cell divisions that are regulated by the highly conserved PAR polarity proteins. We used a fast-acting temperature-sensitive mutation that triggers a SAC response by inducing monopolar spindles, combined with live imaging, to determine whether the strength of the SAC varies between different cell lineages during embryogenesis. In agreement with a recent report, we found that the strength of the SAC scales with cell size, with smaller cells showing a stronger SAC response. Interestingly, however, cells in the germline lineage have a stronger SAC than would be predicted based solely on cell size. We found that enhanced checkpoint activity at the two-cell stage, in the smaller germline P1 blastomere, relative to its larger somatic sibling (AB), is only partially dependent on cell size, indicating that increased SAC activity in P1 depends on the asymmetric partitioning or control of checkpoint regulators. Indeed, in the absence of PAR proteins, when differences in both cell size and asymmetric segregation of cell fate determinants are disrupted, the SAC response in P1 and AB is identical. Neither MDF-1 nor BUB-3, two core SAC proteins, are enriched in P1 relative to AB, suggesting that enhanced SAC activity in P1 may be achieved via means other than simply increasing the concentration of SAC proteins. We are currently investigating whether recruitment of SAC proteins to unattached or improperly attached chromosomes differs between AB and P1. Altogether, our results suggest that enhanced SAC regulation may be a feature of germline cells throughout development and point to a novel interaction between PAR polarity regulators and the SAC.

W431 The balance of PAR polarity dictates cellular division patterning. *Yenwei Lim*[1], Fumio Motegi[1,2,3]. 1) Temasek Life-science Laboratory, Singapore, SG; 2) Mechanobiology Institute, Singapore, SG; 3) National University of Singapore, Singapore, SG.

A hallmark of living cells is the ability to generate copies of them but also to give rise to differentiated cell types. Every cell has to make a binary choice between symmetric or asymmetric cell divisions for cell fate diversification and tissue homeostasis during development. However, much remains unknown about the mechanism behind the cellular division making. To assess the mechanisms underlying the regulatory switch of division patterns, we have developed a system with *C. elegans* two-celled zygotes, which maintain robust developmental program, dictating the anterior and posterior blastomeres to commit symmetric and asymmetric division, respectively. By artificially manipulating spatial pattern of PAR polarity and segregation of fate determinants, we found that tipping the balance of antagonizing PAR proteins, PAR-2 and PAR-6, is sufficient to reprogram cell division patterns, resulting in all combinations of asymmetric and/or symmetric divisions at two-celled zygotes. The choice of division patterns does not rely on segregation of fate determinants, cellular size asymmetry, and cell cycle asynchrony. Our findings support the model, where balance between antagonizing PAR levels within a cell is the critical determinant for its choice in division patterns.

W432 Unraveling cell polarity dynamics with single-cell biochemistry. *Daniel J. Dickinson*, Bob Goldstein. Department of Biology and Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC.

Cell polarity is a fundamental feature of eukaryotic cells and plays a major role in many developmental processes. The conserved PAR protein system mediates polarization in a wide variety of animal cell types including epithelia, neurons and stem cells. PAR proteins localize asymmetrically within a cell and direct the polarization of downstream cellular processes. Although some in vitro binding interactions between PAR proteins are known, a fundamental unanswered question is how PAR proteins are organized biochemically into a signaling network that can mediate cell polarization. To address this question, we have developed a method to quantify protein-protein interactions at the single-molecule level, and with temporal resolution, in single cells. We are applying this approach to the *C. elegans* zygote, a single cell that polarizes in a defined manner with known and reproducible timing. We have identified PAR protein complexes that are specifically up- or down-regulated as the zygote polarizes. In particular, our data identify PAR-3 oligomerization as a key regulatory node for controlling cell polarization: PAR-3 forms large oligomers during polarity establishment, but these oligomers are absent in both stably polarized and non-polarized cells. Quantitative live imaging experiments suggest that PAR-3 oligomerization may contribute to polarity establishment by facilitating redistribution of the PAR-3/PAR-6/aPKC complex to the anterior half of the zygote. Ongoing experiments that combine single-cell biochemistry, quantitative live cell imaging, CRISPR/Cas9-induced targeted mutations and computational modeling in this simple system will reveal how regulated interactions between PAR proteins contribute to the establishment and maintenance of cell polarity.

W433 A Critical Role for Lipid Synthesis and Polyunsaturated Fatty Acids in *C. elegans* Early Embryonic Development. *J. S. Watts*[1], Diane Morton[2], Kenneth Kemphues[2], Jennifer Watts[1]. 1) Washington State University, Pullman, Wa; 2) Cornell University, Ithaca, NY.

The transition from oocyte-to-embryo is a dramatic process in which the previously quiescent oocyte undergoes a series of highly coordinated events that lead to maturation, fertilization, and initiation of mitotic divisions. In the nematode *Caenorhabditis elegans*, this process occurs rapidly and continuously when reproductive maturity is reached. In the short time between fertilization and the first mitotic division, the *C. elegans* embryo completes meiosis, establishes a polarity axis critical for development, and forms a complex multilayered eggshell. A growing body of evidence indicates that *de novo* lipid synthesis and lipid modification are critical for these early embryonic events. Here, we demonstrate the central role that the *C. elegans* holocarboxylase synthetase, BPL-1 performs in fatty acid *de novo* synthesis and in the early embryo. Mutations in the *bpl-1* gene are maternal-effect lethal, and cause defects in PAR polarity, meiosis, and synthesis of the eggshell permeability barrier. We found that a major consequence of disrupting BPL-1 and other *de novo* synthesis genes was a change in fatty acid composition, specifically, a large decrease in polyunsaturated fatty acids (PUFAs). The decrease in PUFAs was much greater in embryos than in

the parent, suggesting that maintenance of embryonic fatty acid composition is more dependent on the lipid biosynthesis machinery than the soma. We provide evidence that dietary malonyl-CoA and biotin support *de novo* synthesis in the whole worm, but not in the embryo, which helps to explain the greater need for *de novo* lipid synthesis machinery in embryos. Further, analysis of fatty acid desaturase mutants demonstrates that PUFAs contribute to synthesis of the embryonic permeability barrier and completion of meiosis. Our evidence supports a model in which dietary and *de novo* synthesized malonyl-CoA converge to support *de novo* synthesis of fatty acids and maintenance of lipid composition in *C. elegans*, but in the sequestered environment of the early embryo, dietary support is unavailable, increasing the importance of the fatty acid *de novo* synthesis machinery to maintain fatty acid composition and to synthesize the specific lipids required in the embryonic permeability barrier.

W434 The forkhead transcription factor UNC-130 integrates both BMP and Notch signaling to regulate dorsoventral patterning of the *C. elegans* postembryonic mesoderm. *Qinfang Shen*, Herong Shi, Leila Toulabi, Erin Nicklow, Jun Liu. Cornell University, Ithaca, NY.

The *C. elegans* postembryonic mesoderm, the M lineage, exhibits distinct dorsoventral asymmetry: the dorsal side produces two non-muscle coelomocytes (CCs), while the ventral side produces two sex myoblasts (SMs). We have previously shown that LIN-12/Notch signaling and the antagonism of BMP signaling by the Schnurri protein SMA-9 function independently to promote ventral and dorsal M lineage fates, respectively (Foehr and Liu, 2008). How these distinct signaling inputs are integrated is not known. We have found that the forkhead transcription factor UNC-130 is one of the key factors that function to integrate these distinct signaling inputs, and that this function of UNC-130 is independent of UNC-129, a TGF-beta factor whose expression in ventral bodywall muscles is known to be regulated by UNC-130 (Nash et al., 2000). A functional UNC-130::GFP is exclusively expressed in the ventral M lineage starting at the 8-M stage. We have found that the ventral M lineage expression of UNC-130::GFP requires LIN-12/Notch signaling, while the lack of UNC-130::GFP expression in the early M lineage and the dorsal M lineage is due to the antagonism of BMP signaling by SMA-9. We further showed that *unc-130(0),* but not *unc-129(0),* mutation can suppress the M lineage dorsal-to-ventral fate transformation defect of *sma-9(0)* mutants. These findings provide critical molecular evidence for the role of SMA-9/Schnurri in antagonizing BMP signaling in *C. elegans*. *unc-130(0)* mutants have low penetrance of dorsoventral patterning defects in the M lineage, suggesting that additional factors function together with UNC-130 to integrate the two signaling inputs. Current work focuses on identifying these additional factors.

W435 VPR-1 MSP domains coordinate reproductive development with striated muscle metabolism. *Timothy Cole*[1], Jessica Schultz[1], Jack Vibbert[1], Pauline Cottee[1], Hieu Hoang[1], Se-Jin Lee[1], Sung Min Han[1], Jin Chen[2], Michael Miller[1]. 1) University of Alabama Birmingham, Birmingham, AL; 2) Vanderbilt University, Nashville, AL.

The major sperm protein domain (MSP) is an evolutionarily conserved immunoglobulin-like structure with extracellular signaling and intracellular functions. The *C. elegans* genome encodes numerous proteins containing MSPs, including about 28 isoforms expressed specifically in sperm. *vpr-1* encodes a type II endoplasmic reticulum protein with an N-terminal MSP, coiled coil motif, and C-terminal transmembrane domain. This broadly expressed, ancestral form has homologs in most animal species called VAPs. Human VAPB/ALS8 is associated with amyotrophic lateral sclerosis (ALS), a muscle disease caused by motor neuron degeneration. We have shown that the VAP MSP is proteolytically liberated from the transmembrane domain in the cytosol and secreted by an unconventional mechanism. In *C. elegans*, the secreted MSP interacts with the CLR-1 Lar-like receptor, thereby promoting mitochondrial localization to body wall muscle I-bands (Han et al. 2012 and 2013). Here we show that muscle mitochondrial abnormalities emerge during larval development. In addition to muscle defects, *vpr-1* null mutants are sterile, due to arrested gonad development at the L2-L3 stage. Genetic mosaic and cell type specific expression studies suggest that the germ line, nervous system, and intestine are cellular sites of VPR-1 MSP secretion. Using Cas9 genome-editing technology, we show that endogenous CLR-1 is expressed throughout the muscle plasma membrane in larval and adult worms. MSP to CLR-1 signaling is sufficient to remodel muscle mitochondria during the L4 stage and adulthood, concurrent with gamete development. We used the binary Q system to temporally control VPR-1 expression. The results indicate that VPR-1 is specifically required for gonad development in a short time window around late embryogenesis or early L1. In mammals, VAP MSPs are found in blood and cerebrospinal fluid (Tsuda et al. 2008; Deidda et al. 2014). Similarly, our studies in *C. elegans* are consistent with VPR-1 MSP being secreted into the pseudocoelom. We are also characterizing mouse Vapb mutants, which have muscle mitochondrial abnormalities in fast-twitch skeletal muscle fibers. Taken together, our data support the model that secreted VAP MSP domains coordinate gonad development with energy metabolism in the neuromuscular system. These results have provocative implications for ALS and other motor neuron degeneration diseases, such as spinal muscular atrophy and Kennedy's disease.

W436 Sensory Activity Maintains Proper Neural Connectivity in *C. elegans*. *Joy Li*, Kristine Andersen, Benjamin Barsi-Rhyne, Jackie Pyle, Kristine Miller, Christopher Vargas, Aruna Varshney, Bryan Tsujimoto, Alan Tran, Alex Duong, Joori Park, Emma Holdrich, Miri VanHoven. San Jose State University, San Jose, CA.

Neuronal activity has been implicated in the establishment and maintenance of appropriate synaptic connections in vertebrate and invertebrate systems. However, the molecular mechanisms by which neuronal activity affects connectivity are poorly understood. To

understand this process, we have focused our studies on the PHB phasmid sensory neurons. The PHB neurons mediate an aversive response to low concentrations of sodium dodecyl sulfate (SDS) (Hilliard et al., *Current Biology*, 2002). In response to SDS, PHB neurons terminate backward movement via their connections with AVA interneurons. Our preliminary results using the WincG.2 cGMP biomarker (a kind gift from N. L'Etoile) indicate that exposure to behaviorally relevant concentrations of SDS results in an increase in cGMP in PHB sensory neurons. We are currently taking a genetic approach to elucidating the pathway by which SDS is sensed by the phasmid neurons using a high throughput assay adapted from the method developed by Hilliard and colleagues (*Current Biology*, 2002). Using this assay, we find that *odr-3*/*Gαolf* and *tax-2*/*CNG-channel β subunit*, in addition to previously discovered *tax-4*/*CNG-channel α subunit* (Hilliard et al., *Current Biology*, 2002), are required for SDS chemosensation. To determine if defects in sensory signaling affect sensory synapses, we utilized the split-GFP-based trans-synaptic marker NLG-1 GRASP (Neuroligin-1 GFP Reconstitution Across Synaptic Partners) to visualize synapses between PHBs and AVA interneurons in live animals. Interestingly, we find that odr-3/*Gαolf* mutants have synapses that are normal at the L1 stage but significantly reduced in later larval stages, while phasmid neuron morphology appears normal. Cell-specific rescue experiments indicate that odr-3/*Gαolf* functions in PHB neurons. Subcellular localization of odr-3/*Gαolf* shows localization to the PHB cilia, consistent with a role in sensory signaling being required to maintain synaptic integrity. These results indicate that *C. elegans* may be a powerful model organism for elucidating the molecular mechanisms by which sensory activity affects synaptic connectivity. Our future goals are to identify the remainder of the chemosensory signaling pathway and to further characterize the mechanism by which sensory activity maintains synapses using molecular genetic and physiological approaches. W437 A transient, pre-cuticular apical extracellular matrix defines tiny tube diameter. *J. D. Cohen*, H. K. Gill (co first author), R. Forman-Rubinsky, M. V. Sundaram. University of Pennsylvania SOM, Philadelphia, PA.

Apical extracellular matrix (aECM) shapes apical domains of many epithelia, but the mechanism by which it does so is still poorly understood. The aECM contains glycosaminoglycans and various glycoproteins, including mucins and zona pellucida domain (ZPD) proteins. Many ZPD proteins form fibrils via the ZPD, but how fibril formation is controlled and how fibrils influence cell shape is not clear. Loss of ZPD proteins causes a number of human diseases, including chronic kidney disease, vascular disease, and deafness. We are interested in the role of the aECM and ZPD proteins in stabilizing seamless tubes, a specialized cell type found in capillary beds of the mammalian vascular system in which a single cell encloses a lumen without junction along its length. By forward genetic screening, we identified 85 alleles required for maintaining the duct cell, a seamless tube of the *C. elegans* excretory system. Two of these alleles disrupt *let-653*, which encodes a secreted ZPD protein that also contains mucin-like and PAN-Apple domains (putative carbohydrate or protein interaction domains also found in plasminogen and other blood coagulation proteins). LET-653 is present within the developing duct lumen as the duct elongates from a simple cylinder to a highly elongated and asymmetric shape, but then disappears prior to the bulk of cuticle secretion. In *let-653* mutants, duct lumen diameter becomes irregular during elongation and the lumen and cell eventually fragment, showing that LET-653 is essential for tube integrity. The LET-653 ZPD, but not the N-terminal PAN domains, is sufficient to rescue these duct cell defects. To address the mechanism by which LET-653 defines lumen diameter, we turned to the much larger vulva lumen, whose shape LET-653 subtly influences. Tagged LET-653 was found in two distinct pools within this lumen: at the apical membrane, where it was highly stable as assessed by FRAP, and in the center of the vulva, where it was mobile. Structure-function analyses revealed that LET-653's ZPD was necessary and sufficient for the apical localization, while the PAN domains localize the protein to the center of the vulva lumen. Ectopic expression of full-length LET-653, but not the PAN domains alone, could expand lumen diameter in the developing gut tube, where LET-653 is not normally expressed. Together, these data support a model in which the PAN domains regulate the ability of the LET-653 ZPD to interact with other factors at the apical membrane, and this ZPD interaction promotes expansion of lumen diameter. We are currently testing if other genes identified in our screen might encode the apical factor(s) that interact with LET-653 for this mechanism.

W438 Rotating and elongating embryos: SPIM microscopy reveals how planar polarity could be established during morphogenesis. *X. Yang*[1*], T. Ferraro[1], J. Pontabry[2], N. Maghelli[3], L. Royer[3], S. Grill[3], G. Myers[3], M. Labouesse[1]. 1) Institut de Biologie Paris-Seine, Paris, FR; 2) Institut de Genetique et de Biologie Moleculaire et Cellulaire, Illkirch, FR; 3) Max Planck Institute of Molecular cell Biology and Genetics, Dresden, Germany.

The process of morphogenesis in *C. elegans* embryos is largely driven by epidermal cells. Unlike in *Drosophila* and zebrafish embryonic development, no cell division or cell rearrangement is involved in *C. elegans* morphogenesis. Cell shape changes within the epidermis, which is characterized by junction lengthening along the anterior/posterior direction, play a key role in this process. The nature and the mechanical forces stimulating junction lengthening, as well as the cellular mechanisms involved in their lengthening are not understood.

Our lab observed that junction elongation along anterior/posterior (A/P) direction increases after muscle becomes active, and fails in muscle defective embryos. To better understand which role muscles play in driving epidermal cell junction lengthening during embryo elongation, we examined the global and local movement patterns using Single Plane Illumination Microcopy (SPIM), focusing on epidermal adherens junctions and muscle nuclei. We analyzed so far four wild-type embryos, five muscle defective embryos and twelve Rho-kinase mutant embryos. We found that wild-type embryos rotated strongly soon after muscle became active, and equally frequently to an outward or inward direction. However, muscle defective and Rho-kinase mutant embryos, which stop elongation at the 2-fold stage, scarcely rotated, suggesting that rotations are important for embryo elongation. Using cross-correlation analysis to compare the perimeter and area changes of each seam cell, we observed that the head, body and tail mechanically behaved as partially independent entities. This local pattern was lost in muscle defective and Rho-kinase mutant embryos. We next sought to understand how such movements could account for the polarized extension of

junctions along the A/P direction, keeping in mind that *C. elegans* embryos are radially symmetric. By measuring the distance between two dorsal or ventral muscle nuclei, respectively, we found that muscles on both sides generally contract alternatively, accounting for the rotation movement. Analysis of seam cell roughness and aspect ratio showed that junctions were stretched along the A/P direction when seam cells were positioned outwards during rotation. This asymmetric muscle activity defines the source of polarity in *C. elegans* embryo and provides the local driving force of epidermis stretching. Furthermore, we propose that *C. elegans* embryos extend in a ratchet mode due to the alternate pattern of muscle contractions.

W439 UNC-33/CRMP inhibits growth cone protrusion in axon repulsion from UNC-6/netrin. *Mahekta Gujar*, Erik Lundquist. University of Kansas, Lawrence, KS.

Previous studies showed that UNC-6/Netrin and its receptors UNC-40/DCC and UNC-5 control axon guidance by regulating protrusion of growth cone lamellipodia and filopodia (Norris et al., 2011; Norris et al., 2014). UNC-6 stimulates protrusion in growth cones attracted to UNC-6 via the UNC-40 homodimeric receptor, and inhibits protrusion in growth cones repelled from UNC-6 via the UNC-5/UNC-40 heterodimeric receptor. Protrusion via UNC-40 requires CDC-42, the Rac GTPases MIG-2 and CED-10, the Rac GEF TIAM-1, and the actin modulating molecules Arp2/3 and UNC-115/abLIM. We delineated a pathway downstream of UNC-5/UNC-40 required to inhibit protrusion that also involves the Rac GTPases and a distinct GEF, UNC-73/Trio, as well as the microtubule-interacting protein UNC-33, similar to Collapsin response mediating protein (CRMP). In repelled VD growth cones, it is likely that both of these complexes are active, as *unc-40* mutants suppress the excess growth cone protrusion of *unc-5* mutants (Norris et al., 2011). UNC-5 and UNC-6 restrict F-actin accumulation to the dorsal, protrusive region of the VD growth cone (Norris et al., 2011).

unc-33 mutant VD growth cones resembled *unc-5*, with excess lamellipodial and filopodial protrusion. We used EBP-2::GFP expression in VD neurons to monitor microtubule + ends in VD growth cones. We found that *unc-33* mutants displayed greatly increased numbers of EBP-2::GFP puncta in VD growth cones and protrusions, suggesting that UNC-33 normally prevents MT + end accumulation in growth cones. *unc-44/*ankyrin mutants showed the same phenotype. Importantly, *unc-5* mutants also showed increased numbers of EBP-2::GFP puncta in growth cones, consistent with UNC-33 acting in the UNC-5 pathway. Interestingly, *unc-73(rh40)*, which specifically affects the Rac GEF domain, did not cause increased EBP-2::GFP puncta despite having excessively protrusive growth cones similar to UNC-33, indicating that increased numbers of EBP-2::GFP puncta were not a secondary consequence of an enlarged growth cone. *unc-73(e936)*, which affects both the Rac and Rho GEF domains, did show increased EBP-2::GFP puncta similar to *unc-33.* These experiments suggest MT-dependent and independent mechanisms, and possibly that the MT-dependent mechanism involves Rho and the independent mechanism involves Rac and possibly actin. In sum, these studies indicate that growth cone protrusion can be inhibited by restricting MT + ends from growth cones, and that UNC-33 is involved in this process. Asymmetric regulation of UNC-33 across the growth cone might result in directed migration away from UNC-6 in axon repulsion.

W440 WAVE/SCAR promotes alpha-catenin accumulation and junctional maturation in developing *C. elegans* epithelia. *Martha Soto*, Sofya Borinskaya, Falshruti Patel, Yelena Bernadskaya, Sailaja Mandalapu, Maria Agapito, Maryam Honarbakhsh. Rutgers - RWJMS, Piscataway, NJ.

Actin is an integral component of the apical junction of epithelial cells. However, the function of the branched actin network at apical junctions is still not clear. We have conducted genetic screens for the essential regulators of cell migrations during *C. elegan*s embryonic morphogenesis and identified a pathway that includes the GTPase Rac1/CED-10, the WAVE/SCAR/GEX complex and the Arp2/3 complex. Consequently we have shown that these branched actin regulators promote enrichment of membrane proteins required for apical junction development in *C. elegans* epithelia. We therefore investigated how Arp2/3 and its WAVE/SCAR nucleation promoting factor help build and maintain apical junctions. TEM studies showed that depletion of WAVE/SCAR components post-embryonically results in reduced size of adherens junctions. This is similar to the effects of depleting either of two *C. elegans* apical junction complexes, the Cadherin Complex or the DLG-1/AJM-1 Complex. Live imaging in embryos showed that WAVE/SCAR and both of these *C. elegans* apical junction complexes promote F-actin accumulation at the apical junction. Accumulation of alpha-catenin/HMP-1, the Cadherin Complex component that binds F-actin, is greatly altered in embryos depleted of WAVE components. Further, WAVE can immunoprecipitate alpha-catenin/HMP-1 and DLG-1/Discs Large, components of two *C. elegans* apical junction complexes. Our studies suggest that distinct *C. elegans* apical junction complexes help recruit WAVE/SCAR, which in turn leads to the enrichment and retention of alpha-catenin at the apical junction, resulting in robust apical actin accumulation.

W441 Mechanical forces drive neuroblast morphogenesis and are required for epidermal enclosure. *A. J. Piekny*, K. Mastronardi, D. Wernike, K. Larocque. Concordia University, Montreal, Quebec, CA.

We recently found that the neuroblasts (neural precursor cells) undergo morphogenetic changes concomitant with the overlying epidermal cells during *C. elegans* ventral enclosure. These events occur during mid-embryogenesis, and may help prepare the embryo to subsequently elongate into the long, thin worm. Subsets of neuroblasts are initially distributed as columns across the embryo, and subsequently organize into ring-like patterns, followed by their redistribution into rows that follow the anterior-posterior axis of the embryo. The formation of similar patterns called rosettes is required for the reorganization and elongation of epithelial tissue in other metazoans, which is mediated by myosin activity and changes in adhesion junctions that tether neighbouring cells. In the neuroblasts, we observed the accumulation of myosin foci and changes in the localization of the adhesion junction components E-cadherin and α-catenin during their reorganization. Further, myosin is required in the neuroblasts for ventral enclosure, and we propose that mechanical forces in the neuroblasts influence constriction of the overlying epidermal cells. The formation of at least one of the rosettes coincides with migration of the overlying ventral epidermal cells, and disrupting neuroblast cell division alters epidermal cell migration as well as the distribution of myosin in these cells. Thus, neuroblast

morphogenesis could 1) decrease the surface area of the neuroblast substrate, making it easier for the overlying epidermal cells to migrate and/or 2) generate tension that is sensed by the epidermal cells and influences active myosin localization. We are currently testing these models by further analyzing the precise movements and shape changes of the neuroblasts that form the rosette(s), and by monitoring how their disruption influences the overlying epidermal cells. In addition, we are using AFM (atomic force microscopy) to determine if there are changes in tension/elasticity of the neuroblasts during ventral enclosure, and how myosin disruption alters this tension. The coordination of myosin-dependent events and forces between cells in different tissues could be a common theme for coordinating morphogenetic events during metazoan development.

W442 Morphogenic movements and cell signalling events during gland cell and pharyngeal organ development in *Caenorhabditis elegans*. *J. Kormish*[1], S. Tkachuk[1], S. R. Kim[1], M. Burg[1], O. Atta[1], M. Singh[1], E. Bennici Clendinnen[1], W. H. Raharjo[2]. 1) University of Manitoba, Winnipeg, Manitoba, CANADA; 2) University of Calgary, Calgary, Alberta, CANADA.

An important question in developmental genetics is how distinct cell types migrate, change shape and interact in a coordinated manner to form an organ. *Caenorhabditis elegans,* with its powerful genetics, invariant cell lineage and optical transparency that allows for live-imaging microscopy during embryo development, is an excellent tool to study cellular migration and coordination of morphogenesis during organ development. The *C. elegans* pharynx is a muscular feeding organ of the upper digestive tract. The pharynx is relatively simple organ, it consists of about 95 cells, but contains diverse cell types including muscle, neuronal, structural, epithelial, and secretory gland cells. During pharynx morphogenesis, these diverse cell types coordinate their movements to rearrange themselves from a "ball of cells" into an extended tubular structure. In my lab, we have focused our studies on the development of the pharyngeal gland cells. Live imaging studies have been used to determine that these cells, in particular the dorsal gland cell, create a unicellular extension through a process called retrograde extension. During this morphogenic process, the cell is born in the anterior aspect of the pharyngeal primordium and migrates to the posterior pharynx leaving a unicellular projection in its migratory wake.

Progress in understanding the molecular underpinnings to retrograde extension will be discussed. A forward genetic screen isolating defects in gland cell migration has been completed and 60 alleles have been isolated that display gland cell under-migration or over-migration defects. Previous work has determined that the FGFR pathway*, egl-15*, and the integrin receptor pathway, *ina-1*, provide a migratory stop cue during gland cell migration. Despite extensive efforts using candidate approaches, identification of downstream components to these receptors during gland migration have been unsuccessful. Loss of function mutations in a gene called *cam-1* display a gland cell under-migration phenotype. The CAM-1 protein is a ROR tyrosine kinase receptor that binds the Wnt ligand and induces a kinase-dependent response to provide a positive cue for gland migration. The forward genetic screen has identified several strains with Cam-1-like gland cell under-migration phenotypes as well as Egl-15 and Ina-1-like over-migration defects. Preliminary mapping of two strains that display penetrant under-migration defects have isolated two alleles to chromosome locations distinct from known *cam-1* pathway components. Further mapping studies, whole genome sequencing and genetic epistasis will be used to define the genetic pathways regulating gland cell migration during pharynx development.

W443 DAF-7/TGFβ signaling in the *C. elegans* germline stem cell niche. *Olga Pekar*[1], Maria C. Ow[2], Kailyn Y. Hui[3], Marcus B. Noyes[3], Sarah E. Hall[2], E. Jane Albert Hubbard[1]. 1) Skirball Institute of Biomolecular Medicine and Department of Cell Biology, NYU School of Medicine, New York, NY; 2) Department of Biology, Syracuse University, Syracuse, NY; 3) Institute for Systems Genetics, NYU School of Medicine, New York, NY.

An appropriate molecular environment is essential for stem and progenitor cells to decide whether to remain undifferentiated or to undergo differentiation. We are using the *C. elegans* germ line as a model for understanding how this decision is influenced by changes in an animal's environmental conditions.

During larval development in *C. elegans,* a pool of proliferative germline stem/progenitor cells accumulates, from which gametes are produced. Previously, our lab showed that the DAF-7/TGFβ-related signaling pathway modulates the accumulation of these cells in response to sensory cues, independent of previously defined roles for this pathway in the dauer decision and lifespan regulation. The expression of *daf-7* in ASI chemosensory neurons provides a link between environmental changes perceived by the animal and the number of proliferative germ cells. The TGFβ receptor (TGFβR) complex and its downstream transcriptional regulatory effectors act in the distal tip cell (DTC), the germline stem cell niche.

We sought the molecular link between TGFβR signaling in the DTC and the response in the germ line. GLP-1/Notch signaling maintains the proliferative pool of germ cells in response to DSL-family ligands LAG-2 and APX-1 produced by the DTC. However, previously, we found that TGFβR signaling can influence germ cell accumulation in a *glp-1*-independent manner, suggesting that it acts in parallel to GLP-1/Notch.

More recently, we found that TGFβR signaling can also promote the expression of *lag-2* in the DTC. This conclusion is based on results obtained using new transcriptional reporters and fluorescence *in situ* hybridization analysis. Expression of *lag-2* is reduced upon disruption of TGFβ signaling, but is restored in the absence of *daf-3* or *daf-5*, the negatively regulated downstream effectors of DAF-7/TGFβ signaling. By both yeast and bacterial one-hybrid assays, we found evidence for direct interaction between the DNA-binding domain of DAF-3 (a homolog of Smad4, that in DAF-7 pathway acts as a transcriptional repressor) and the *lag-2* promoter. By ChIP, we identified potential DAF-3 binding motifs in the same region of the promoter. Currently, we are mutating these sites *in vivo* by CRISPR/Cas9. Initial results from reporter assays indicate that eliminating these motifs abrogates the response to TGFβR signaling, suggesting that they directly mediate the response of *lag-2* to TGFβ.

W444 The combined activity of CPB-1^{CPEB} and GLD-3$^{Bic\text{-}C}$ opposes FBF^{Pum} to prevent the sperm-to-oocyte switch in *C. elegans* males. *C. R. Eckmann*[1,2], C. Hirsch[1], R. Minasaki[1,2]. 1) MPI-CBG, Dresden, DE; 2) Martin-Luther-University Halle-Wittenberg, Halle (Saale), DE.

Gamete formation requires genetic programs that coordinate germ cell differentiation and meiosis with sexual fate choice and maintenance. At the posttranscriptional level these programs are integrated via a dense network of RNA-binding and RNA-modifying proteins. Especially

translational regulators, such as PUF, Nanos and cytoplasmic polyadenylation element-binding (CPEB) family proteins are identified in many organisms as molecular nodes of the germ cell fate decision machinery. *Caenorhabditis elegans* germ cells undergo a programed sperm-to-oocyte switch in the hermaphrodite to produce -in essence- a self-fertile female animal. This is governed by the sequential action of the RNA-binding protein FOG-1^{CPEB}, which initiates male fate specification, and the FBF^{PUF}/NOS-3^{Nanos} RNA regulatory complex that blocks several male fate-promoting (‘*fem’* and ‘*fog’*) genes by preventing their efficient translation, thus limiting sperm production to the final larval stage prior to adulthood. Previously, we showed that in males the Bicaudal-C protein GLD-3 antagonizes FBF-mediated translational repression: while *gld-3* mutant germ cells initiate spermatogenesis during larval stages, adults often fail to maintain their male fate and switch to oogenesis in an *fbf*-dependent manner, suggesting that GLD-3^{Bic-C} is an important player but not the only one in males to keep the female fate-promoting machinery in check.

In search of additional regulators, we identified CPB-1^{CPEB} as a molecular opponent of FBF in sexual fate maintenance. Although *cpb-1* hermaphrodites produce -compared to wild type- a similar number of sperm, indicating no crucial role in the sperm-to-oocyte switch fate, we confirmed a previously suggested role in sperm differentiation; all animals are sterile. Importantly, we found that a large fraction of adult males produce oogenic cells after an initial period of spermatogenesis. Our genetic analysis places *cpb-1* in the core sex determination pathway upstream of *fbf* and in parallel to *gld-3*. Intriguingly, all *gld-3; cpb-1* double mutant male gonads produce exclusively oocytes suggesting that CPB-1 works redundantly with GLD-3 to antagonize FBF, which is further corroborated by their expression patterns. To our surprise, detailed structure-function analysis of transgenic rescuing experiments suggested that CPB-1’s RNA recognition motifs are essential for male fate maintenance, rather than a previously mapped FBF-binding region in its amino terminus. Therefore, CPB-1 likely functions in its capacity as an RNA-binding protein to target mRNAs required for maintenance of male germ cell fate. Our findings reveal a novel role for CPEBs and contrast to work in mammals where a transcriptional network is a key regulator of sexual fate maintenance.

W445 *top-2* is required for proper chromosome segregation during male meiosis in *C. elegans*. *A. N. Jaramillo-Lambert*, H. Smith, A. Golden. NIDDK/NIH, Bethesda, MD.

Type II DNA topoisomerases play a critical role in chromosome fidelity by alleviating topological stresses that arise within chromosomes. Topo II is a large ATP-dependent homodimeric enzyme. Each subunit breaks one DNA strand, passes a second unbroken strand through the break, and then reseals the break. Thus, during mitotic divisions, Topo II enzymes solve topological problems that arise during replication, transcription, sister chromatid segregation, and recombination. In contrast to the single round of DNA replication followed by a single nuclear division during mitosis, meiosis has one round of DNA replication followed by two nuclear divisions. In meiosis II sister chromatids segregate from each other similar to mitosis. Meiosis I, on the other hand, segregates homologs, which requires pairing, synapsis, and recombination. Studies in mammals, yeast, and *Drosophila* have demonstrated that Topo II plays a role in homologous chromosome segregation at meiosis I. However, the exact role Topo II plays during meiosis is unknown. In a screen re-examining temperature sensitive legacy mutants identified thirty years ago, we identified a *C. elegans* allele of Topo II, *top-2(it7ts)*. Initial analysis found that *top-2(it7ts)* mutant males produce dead embryos, even when fertilizing wild-type oocytes. Characterization of early embryonic events indicates fertilization is successful and that sperm components (e.g. centrosomes) are transmitted to the embryo. However, sperm chromatin is not detected in these fertilized embryos. Examination of *top-2(it7ts)* male germ lines revealed that the sperm DNA fails to properly segregate during the meiotic divisions. Chromatin bridges form during anaphase I and the chromatin becomes trapped in the residual body. Failure to segregate DNA into the spermatids results in anucleate sperm that are capable of fertilization; early embryonic events appear normal but embryos arrest around the 200-cell stage. *top-2 (it7ts)* chromosome segregation defects observed during anaphase I are not due to residual entanglements incurred during meiotic DNA replication and are not a consequence of recombination defects. We are currently evaluating the role of *top-2* in chromosome structure.

W446 The t-SNARE *syx-7* promotes cytokinesis during sperm meiosis. *K. Fenker*, G. Stanfield. University of Utah, Salt Lake City, UT.

Mature sperm are specialized cells that are both motile and capable of fertilizing oocytes. To reach this stage, sperm undergo an intricate process of differentiation, and there are many interesting questions regarding the molecular mechanisms guiding their development. We are using *C. elegans* sperm to investigate some of these questions, and have recently identified the t-SNARE syntaxin 7 (*syx-7)* as a new member of the *spe* (spermatogenesis defective) class of genes, as it plays an important role in sperm development.

syx-7 is an ortholog of mammalian STX12, an endosomal t-SNARE. Using CRISPR/Cas9, we generated several deletion alleles of *syx-7*, and found that loss of the gene significantly reduces fertility of both male and hermaphrodite worms. This reduction in fertility is not due to embryonic lethality or female germline defects, but is caused by defective sperm. In animals lacking *syx-7*, the sperm arrest as large, abnormal cells, often containing four nuclei within a common cytoplasm. Preliminary data suggests *syx-7* mutant sperm have defects in their ability to bud off from residual bodies and form haploid spermatids. To further characterize the defects in *syx-7* mutants, we are using time-lapse microscopy to generate movies of *in vitro* sperm development. So far, our data suggest *syx-7* may function in the membrane dynamics that take place during cytokinesis, possibly through delivery of new membrane components or maintenance of a boundary between the budding spermatid and the residual body. We are working to test these models. We have demonstrated *syx-7* functions in sperm to promote fertility, and we are using strains with a CRISPR-generated *gfp::syx-7* to visualize the protein’s localization. So far, we have shown that GFP::SYX-7 localizes to the sperm as well as other tissues, and we are currently determining the subcellular localization of the protein within sperm during spermatogenesis, particularly during the meiotic cell divisions.

W447 Signaling sperm to stop or go: the seminal fluid protease inhibitor SWM-1 regulates *C. elegans* sperm motility. *Daniela Chavez*, Gillian Stanfield. University of Utah, Salt Lake City, UT.

In the race to fertilize oocytes, sperm cells encounter extracellular environments that affect their success. These environments include male and female reproductive tracts as well as seminal fluid. In many species, proteolysis regulators are abundant in seminal fluid and contribute to various aspects of fertility. In *C. elegans*, protease signals regulate the onset of sperm motility, a process called activation that occurs after mating. Spatial and temporal regulation of motility is critical, as either premature or delayed activation results in significantly reduced fertility. During activation, sperm undergo morphogenesis and develop a pseudopod, which they use to crawl toward oocytes. The secreted protease TRY-5 is present in the male gonad and in seminal fluid, where it is required to activate sperm. Upstream of TRY-5, the secreted protease inhibitor SWM-1 is required to inhibit activation, yet how the protease signal is regulated spatially and temporally to control activation is unknown. To understand how SWM-1 regulates activation, we used CRISPR to tag SWM-1 at its endogenous locus. We find that *swm-1* is expressed in both the gonad and extra-gonadal cells and that SWM-1 protein surrounds spermatids. In vas deferens cells, SWM-1 localizes to vesicles closely associated with the apical membrane. Surprisingly, it is transferred with TRY-5 during mating. How seminal fluid is secreted from these vesicles is unknown and we are using our SWM-1 reporter to analyze vesicle dynamics. Tissue-specific expression shows that vas deferens-derived SWM-1 is at least partially sufficient to regulate activation. Our findings lead to a model where SWM-1 is secreted from the vas deferens to inhibit TRY-5 from activating sperm until mating. Intriguingly, the presence of SWM-1 in seminal fluid suggests an additional post-mating role in the hermaphrodite. In support of this hypothesis, SWM-1 has two trypsin-inhibitor-like (TIL) domains, which have distinct reactive sites and appear to play non-equivalent roles in inhibiting activation. To further investigate the role of SWM-1 in fertility, we are using CRISPR to generate reactive site mutants and we are testing SWM-1 for post-mating roles within the hermaphrodite reproductive tract.

W448 The sperm TRP family channel TRP-3 induces a calcium wave in the fertilized oocyte of *C. elegans*. *J. Takayama*, S. Onami. RIKEN QBiC, Kobe, JP.

Calcium waves during fertilization promote the transition from oocyte to embryo. How the fertilizing sperm induces the calcium waves has been explained either by the action of a soluble sperm-delivered factor or by the ligand-receptor interaction between the sperm and the egg. Calcium influx from the extracellular space through a sperm-derived calcium channel was predicted by the calcium conduit model; however, molecular underpinnings for this model have been elusive. Here we show that the sperm-specific plasma membrane calcium-permeable channel TRP-3 (also known as SPE-41) induces a calcium rise in the oocyte upon fertilization in *C. elegans*. Spinning-disk confocal microscopy and computational image analysis revealed that sperm induce an immediate local calcium rise followed by a propagating calcium wave. This biphasic waveform was recapitulated by a simulation that assumes that the oocyte has calcium-induced calcium release (CICR) machinery. Oocytes fertilized by *trp-3* mutant sperm showed a lack of the local calcium rise and a delay in the onset of the propagating wave. Expression of TRP-3 in sperm by sperm-specific expression drivers could rescue the defects partially. Moreover, the stronger the driver activity was, the larger the local calcium rise and the earlier the onset of the propagating calcium wave became. The correlation between the amplitude of the local calcium rise and the delay in the wave onset was again recapitulated by the simulation based on the CICR model. High-speed calcium imaging of the fertilizing sperm cytoplasm revealed that the sperm calcium concentration increases from a resting level, arguing against the bolus introduction of stored calcium from sperm. Moreover, by observing the fertilization between the oocyte whose plasma membrane was labeled with GFP-fused PH domain and the sperm that expresses TRP-3 fused C-terminally with TagRFP-T, we found that fertilization takes place as a single-round direct plasma membrane fusion. These results suggest that sperm-derived TRP-3 channel induces a local calcium rise in the fertilized oocyte. The local calcium rise would then induce a propagating calcium wave probably by the CICR mechanism.

W449 Maternal MEMI specifies the female meiosis II program in *C. elegans*. *Martin Srayko*, Justus Tegha-Dunghu, Maryam Ataeian, Jens Herzog, Ellen Sykes, Caitlin Slomp, Megha Bajaj. University of Alberta, Edmonton, AB, CA.

In most animals, female meiosis completes only after fertilization. Sperm entry has been implicated in providing a signal for the initiation of the final meiotic processes, however, a maternal component required for this has not been previously identified. We report the characterization of a novel family of three highly similar paralogs (*memi-1*, *memi-2*, *memi-3*) that encode oocyte-specific proteins. A temperature-sensitive dominant mutation, *memi-1(sb41),* was originally identified in a screen for maternal-effect lethal mutations in the Mains laboratory (formerly termed *mel-43*)[1]. *memi-1(sb41)* behaves as a hypermorphic mutation, and embryos from mutant mothers fail to exit female meiosis II properly. A *memi-1(deletion)* exhibits no obvious phenotype, however, loss of all three *memi* paralogs via RNAi causes fertilized oocytes to abort meiosis I during anaphase, "skip" meiosis II, and proceed directly into mitosis. The McNally lab showed that a similar phenotype occurs when sperm-activated oocytes are not fertilized[2], suggesting that the MEMI proteins represent a maternal component of a post-fertilization signal that specifies the meiosis II program. The MEMI proteins are degraded before mitosis and sensitive to ZYG-11, a substrate-specific adapter for cullin-based ubiquitin ligase activity[3,4]. Interestingly, the *memi-1(sb41)* hypermorphic mutation results in inappropriate persistence of MEMI-1, but not MEMI-2 or MEMI-3, protein into mitosis. In order to identify potential activators of the *memi* pathway, we performed an RNAi screen for suppressors of *memi-1(sb41)*. This approach identified a sperm-specific PP1 phosphatase. Because reducing the funciton of this PP1 phosphatase suppresses *memi-1(sb41)*, the PP1 might also be required for normal *memi* activity upon fertilization. We are currently testing the hypothesis that sperm-delivered PP1 activates MEMI to specify meiosis II after fertilization.

W450 ELLI-1, a novel germline protein, modulates RNAi activity and P-granule accumulation in *C. elegans*. *D. Updike*, K. Andralojc, A. Campbell, A. Kelly, M. Terrey, P. Tanner, I. Gans, M. Senter-Zapata, E. Khokhar. Mount Desert Island Biological Laboratory, Bar Harbor, ME.

Germ cells contain non-membrane bound cytoplasmic organelles that help maintain germline integrity. In *C. elegans* they are called P granules; without them, germ cells undergo partial masculinization or aberrant differentiation. Many key P-granule components play roles in both exogenous and endogenous small RNA pathways. CSR-1 represents a small-RNA binding P-granule protein that antagonizes the accumulation of sperm-specific transcripts in developing oocytes. Loss of CSR-1 and its cofactors cause a very specific, enlarged P-granule phenotype. To better understand the function of CSR-1 in P granules, PGL-1::GFP expressing worms were mutated and screened for enlarged P granules. Ten mutants were isolated, including multiple alleles of *csr-1* and its cofactors *ego-1*, *ekl-1*, and *drh-3*. Two alleles are in a novel gene now called *elli-1* (**e**n**l**arged germ**li**ne granules). ELLI-1 becomes expressed in primordial germ cells during mid-embryogenesis and continues to be expressed in the adult germline. ELLI-1 forms cytoplasmic aggregates that do not co-localize with P granules, but instead accumulate in the syncytial cytoplasm of the adult germline. Genes encoding P-granule components, including those in the *csr-1* pathway, are up-regulated in *elli-1* mutants, as are several genes that promote RNAi. This overexpression of RNAi genes is reflected in the enhanced RNAi phenotype of *elli-1* worms. Our results suggest that ELLI-1 is acting to modulate the accumulation of key transcripts required for exogenous and endogenous small RNA pathways.

W451 Cell-cycle quiescence maintains *C. elegans* germline stem cells independent of GLP-1/Notch. *Hannah Seidel*[1], Judith Kimble[1,2]. 1) University of Wisconsin - Madison, Madison, WI; 2) HHMI.

Many types of adult stem cells exist in a state of cell-cycle quiescence, yet it has remained unclear whether quiescence plays a role in maintaining the stem cell fate. Here we establish the adult germline of *C. elegans* as model for facultative stem cell quiescence. We find that mitotically dividing germ cells, including germline stem cells, become quiescent in the absence of food. This quiescence is characterized by a slowing of S phase, a block to M-phase entry, and the ability to re-enter M phase rapidly in response to re-feeding. We also demonstrate that cell-cycle quiescence can maintain the stem cell state. The signaling pathway required for stem cell maintenance under conditions of active proliferation (GLP-1/Notch signaling) becomes dispensable under conditions of quiescence. We find that quiescence stabilizes Notch effector proteins, suggesting that changes in protein stability may underlie the effect of quiescence on stem cell maintenance. We are currently investigating the food signals required for quiescence exit, as well as the role of cell-cycle regulators in maintaining quiescence.

W452 Beyond Cell Death: Systematic Analyses of Non-apoptotic CED-3 Caspase Functions in *C. elegans*. *B. P. Weaver*, Y. M. Weaver, M. Han. HHMI & CU Boulder, Boulder, USA.

Recent findings from several labs, including ours, have implicated important non-apoptotic functions for canonical apoptotic regulators across diverse metazoans including nematodes, flies, and mammals. We recently reported a genome-wide RNAi screen in *C. elegans* that identified numerous genes cooperating with the miRISC to ensure robust development (Weaver, et al. 2014). We showed that one interactor, the CED-3 caspase, previously known for its essential role in apoptosis, had a critical non-apoptotic activity negatively regulating the expression of LIN-28, and likely also LIN-14 and DISL-2 (Dis3l2 ribonuclease) in the LIN-28 pluripotency/ developmental timing pathway in late larval development thereby limiting supernumerary seam cell divisions (Weaver, et al. 2014). In order to systematically investigate the extent of possible other non-apoptotic functions for the CED-3 caspase in *C. elegans* development, we performed a *ced-3(lf)* enhancer screen in the double blind using a genome-wide RNAi approach. Following a secondary RNAi confirmation screen, we identified more than 100 interactors from diverse functional categories including protein stability regulators, signal transduction factors, RNA-binding proteins, and transcriptional regulators, thus implicating the involvement of CED-3 caspase in a wide-range of non-apoptotic developmental regulatory pathways. We sought to identify a downstream target for one of these interactions that resulted in a dramatic larval developmental stall. Using a combination of biochemical methods, genetic methods, and tissue-specific reporters, we found that CED-3 negatively regulated a MAPK pathway in the hypodermis (epidermis), in the absence of stress. We found that aberrant activity of the MAPK pathway was responsible for larval delay and that CED-3 caspase contributed to robust late larval development by downregulating this pathway and thereby ensured proper post-embryonic growth rate during normal development. Altogether, our data support a model wherein CED-3 caspase acts as a pro-differentiation factor in later larval stages that is important to ensure both proper developmental timing (previous findings) while also ensuring timely progress through post-embryonic development (current findings).

W453 Two new genes regulate LIN-28 in the juvenile-to-adult transition. *K. Kiontke*[1], R. A. Herrera[1], E. Vuong[2], E. M. Schwarz[3], D. S. Portman[2], D. H. A. Fitch[1,4]. 1) New York University, New York, NY; 2) University of Rochester, New York, NY; 3) Cornell University, Ithaca, NY; 4) New York University, Shanghai, China.

During the juvenile-to-adult transition at the L4 stage, the tail tip of *C. elegans* males changes shape from long and pointed to short and round. The timing of this tail tip morphogenesis (TTM) is under the control of the heterochronic pathway, best known for scheduling seam cell development. Previous work showed that *let-7* and *lin-41* play a role in the timing of TTM: in loss-of-function mutants of *let-7* and gain-of-function mutants of *lin-41*, TTM is delayed into adulthood. We identified two new genes involved in the timing of TTM, *lep-2* and *lep-5* (H36L18.2). Males mutant in either gene have fully un-retracted tail tips that undergo TTM as adults. Also, mutant adults undergo an additional molt and mutant *lep-2* males show defective mating behavior, suggesting that the gene products of *lep-2* and *lep-5* act not only in the tail tip but also in the body epidermis and nervous system. Unexpectedly, neither mutant has defects in the development of the lateral seam. *lep-2* encodes a Makorin, a member of a family of conserved proteins with putative nucleic acid binding and E3 ubiquitin ligase activities. *lep-5* is a long noncoding RNA (lncRNA), highly conserved within *Caenorhabditis* but not identifiable outside of this genus. SL1-spliced *lep-5* lncRNA is

predicted to adopt a complex secondary structure with multiple stem-loops, at least two of which are necessary for its function.
By testing genetic interactions, we determined that *lep-2* and *lep-5* repress *lin-28*. It is known that *lin-28* is downregulated transcriptionally (by *lin-14)* and post-transcriptionally (by *daf-12, lin-4, lin-66,* and *sea-2)* after the L2 stage to ensure that mature *let-7* microRNA is present during L3. We found that both LEP-2 and *lep-5* lncRNA also down-regulate LIN-28 protein levels post-transcriptionally without affecting *lin-28* mRNA levels. Using a photo-convertible LIN-28::Dendra2 fusion, we determined that LEP-2 and *lep-5* lncRNA promote degradation of LIN-28 protein. This is consistent with the predicted E3 ubiquitin ligase activity of LEP-2. The mechanism for the activity of *lep-5* lncRNA is still unknown. Interestingly, the human homolog of LEP-2—Makorin3—as well as human LIN28b, are involved in the regulation of pubertal timing. Together with our findings in *C. elegans*, this suggests a conserved role of Makorins and LIN-28 in timing of the juvenile-to-adult transition.
The fact that seam cell development is unaffected by mutations in *lep-2* and *lep-5* suggest that developmental timing is regulated in a tissue-specific manner. Therefore, the male tail tip is a valuable model for studying the heterochronic pathway in all its complexity.

W454 The Argonaute VSRA-1 Regulates Gene Expression through Multiple Small RNA Pathways. *Julie M. Claycomb*[1], Monica Z. Wu[1], Shikui Tu[2], Zhiping Weng[2]. 1) Univ. of Toronto, Toronto, ON, Canada; 2) Univ. of Massachusetts Medical School, Worcester, MA, USA.

At the core of small RNA pathways are Argonaute (AGO) proteins, which interact with small RNAs to regulate gene expression in a sequence-specific manner. The characterization of AGOs across species, including a subset of the 26 AGOs in *C. elegans,* has demonstrated that AGOs generally interact with non-overlapping complements of small RNAs to perform distinct regulatory functions. Our lab's previous studies on the CSR-1 22G-small RNA pathway in *C. elegans* provided mechanistic insights into a paradigm-shifting role for nuclear small RNA pathways in activating germline gene expression, instead of silencing as occurs in the vast majority of small RNA pathways, like RNAi.

We set out to characterize a well-conserved nematode AGO that was most closely related to CSR-1. Remarkably, we found that this AGO interacts with multiple classes of small RNAs, including the essential *mir-51* family of microRNAs (*Hs-mir-100*), as well as specific subsets of piRNAs and CSR-1 class 22G-RNAs. Owing to this versatile repertoire of small RNA partners, we named this AGO VSRA-1 (Versatile Small RNAs Argonaute).

Loss of *vsra-1* leads to slower larval development. Consistent with functions related to multiple small RNA classes, *vsra-1* displays synthetic genetic interactions with the AGOs that have previously been shown to act with each type of small RNA (*alg-1*/miRNAs, *prg-1*/piRNAs, *csr-1*/22G-RNAs). Using a combination of CRISPR-Cas9 GFP knock-in strains and antibody staining against endogenous VSRA-1, we determined that VSRA-1 is broadly expressed across most developmental stages and tissues including the germline. *In vivo* reporter assays and mRNA-seq data implicate VSRA-1 in silencing gene expression, including a large portion of germline-expressed genes. Moreover, sequencing of VSRA-1-small RNA complexes indicates that VSRA-1 associated small RNAs all appear to target CSR-1 pathway genes. Thus, we propose a model in which VSRA-1, through a complex network of small RNAs, functions antagonistically to the CSR-1 pathway to maintain germline homeostasis.

We are currently pursuing structure-function analyses, using CRISPR-Cas9 and biochemical experiments, to dissect the loading and specification of VSRA-1 small RNAs. Due to its unique property of association with multiple classes of small RNAs, characterization of this fascinating AGO will reveal novel mechanisms regulating germline gene expression.

W455 ALG-5 interacts with a subset of miRNAs to affect male gene expression and fecundity in *C. elegans*. *T. Montgomery*. Colorado State University, Fort Collins, CO.

C. elegans contains 25 Argonautes, of which, only ALG-1 and ALG-2 are known to interact with miRNAs. ALG-5 belongs to the AGO subfamily of Argonautes, which includes ALG-1 and ALG-2, but its role in small RNA pathways is unknown. We analyzed by high-throughput sequencing the small RNAs associated with ALG-5, ALG-1, and ALG-2. We show that ALG-5 interacts with a subset of miRNAs that overlaps with those bound by ALG-1 and ALG-2. *alg-5* is expressed in the germline during oogenesis and is required for optimal fecundity. *alg-5* mutants display modest changes in gene expression, including upregulation of genes involved in male development. Through an exhaustive analysis of ALG-5, ALG-1, and ALG-2 small RNA interactors, we identified only three new miRNAs, indicating that miRNA identification is nearly saturated in *C. elegans*. We also identified ALG-1 and ALG-2 associated small RNAs that do not resemble canonical miRNAs. Our results provide a near-comprehensive analysis of miRNA-Argonaute interactions in adult *C. elegans* and reveal distinct and overlapping roles for ALG-5, ALG-1, and ALG-2 in development, fecundity, and lifespan.

W456 Toward an understanding of cooperative miRNA-mediated silencing. *M. N. Flamand*[1*], H. H. Gan[2], K. Gunsalus[2], T. F. Duchaine[1]. 1) McGill University, Montreal, Quebec, CA; 2) New York University, New York, NY.

MicroRNAs (miRNAs) are derived from gene-encoded RNA hairpins and play critical roles in development, homeostasis, disease, and environmental responses. In *C. elegans* mature miRNAs are loaded in the Argonautes ALG-1 and ALG-2 and direct gene silencing from within the miRNA-Induced Silencing Complex (miRISC). In animals, miRNAs bind to 3' untranslated regions (UTR) of messenger RNAs (mRNAs) through imperfect base pairing. Because of this imperfect base pairing, the identification of miRNA targets remains a challenge that can only be fully answered through direct functional validation. While several lines of evidence point to the importance of cooperative interactions between miRNA-binding sites on individual target mRNAs, they are still largely investigated as functionally independent regulatory units.

Using a unique *C. elegans* embryonic cell-free system, we had previously shown that miRNA-instigated deadenylation, an important mechanism of silencing, requires target site cooperation. Now exploiting an array of biochemical, computational, genome editing and genetic approaches, we decipher the mechanistic bases for cooperative miRNA-mediated silencing. Our findings reveal that miRNA-binding site cooperation is required to recruit miRISC to non-canonical sites on mRNAs, and that miRISC association is not sufficient for target deadenylation. We further demonstrate ALG-1/2 homo- or hetero-dimerization *in vitro*, thus providing an explanation for cooperation in target site recruitment. Using computational modeling of miRNA and 3'UTR-bound Argonaute dimers, we identified two putative miRISC-miRISC

interaction interfaces. Turning to CRISPR/Cas-9 to engineer mutant strains, we systematically screened candidate dimerization determinants to identify Argonaute residues that are critical *in vivo* for miRNA function, for miRISC interactions, and for mRNA target deadenylation.

Our findings unveil molecular determinants for miRNA cooperation, and suggest that miRISC-miRISC interactions play a cornerstone role in the mechanisms of miRNA-mediated silencing.

W457 A continuum of mRNP complexes in embryonic miRNA-mediated silencing. *Thomas Duchaine*[1], Edlyn Wu[1], Ajay Vashisht[2], Clément Chapat[1], Mathieu Flamand[1], Emiliano Cohen[3], Mihail Sarov[4], Yuval Tabach[3], Nahum Sonenberg[1], James Wohlschlegel[2]. 1) Department of Biochemistry and Goodman Cancer Research Centre, McGill Univ., Montreal, Quebec, Canada; 2) Department of Biological Chemistry, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA; 3) Hebrew Univ., Hadassah Medical School, Jerusalem, Israel; 4) Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany.

MicroRNAs (miRNAs) impinge on the translation and stability of a wide variety of mRNAs, and play key roles in development, homeostasis and disease. The gene regulation mechanisms they instigate are largely effected through the activities and interactions of the CCR4-NOT deadenylase complex, but the molecular events that occur on target mRNAs and lead to silencing are poorly resolved. Using comparative proteomics, we observed a broad convergence of interactions of germ granule and P body mRNP components on AIN-1/GW182 and NTL-1/CNOT1 in the *C. elegans* embryo. We show that the miRISC progressively matures on the target mRNA from a scanning form into an effector mRNP particle by sequentially recruiting the CCR4-NOT complex, and mRNP components such as the decapping and decay, or germ granule proteins. Finally, we provide evidence for a role of intrinsically disordered proteins in embryonic miRNA-mediated silencing. Our findings define dynamic steps of effector mRNP assembly in embryonic miRNA-mediated silencing, and identify a functional continuum between germ granules and P bodies in the *C. elegans* embryo.

W458 Germline- and soma-specific mechanisms of heritable epigenetic silencing at an endogenous locus. *Olga Minkina*, Craig P. Hunter. Harvard University, Cambridge, MA.

Double stranded RNA (dsRNA) introduced into *C. elegans* can move throughout the worm to initiate RNAi-mediated silencing in recipient cells. DsRNA movement, both within a worm and between generations, requires the conserved dsRNA-transporting protein SID-1. I have found that a transgenic multi-copy array of the *sid-1* upstream intergenic region (promoter and 5' UTR) silences *sid-1* and upstream genes in the germline and soma. This is surprising for two reasons. First, arrays containing multiple copies of promoters have never been shown to stably silence endogenous genes. Second, heritable epigenetic gene silencing has not previously been described in the soma in *C. elegans.* Once silenced, the *sid-1* locus can remain silenced for up to 13 generations in the absence of the array. Reminiscent of paramutation, a silenced *sid-1* locus can silence a naive locus introduced by mating in the germline. Surprisingly, transmission of silencing does not require transmission of chromatin. Instead, small interfering RNAs (siRNAs) mediate *sid-1* silencing in the germline; worms containing the *sid-1* promoter array have a three-fold increase in small RNAs targeting the *sid-1* locus. This increase is maintained even in the absence of the array indicating that these small RNAs are likely the transgenerational signal that epigenetically silences *sid-1* in the germline. Genetic analysis reveals that efficient initiation of *sid-1* silencing partially requires the piRNA-stabilizing Argonaute PRG-1 and that maintenance of *sid-1* silencing requires HRDE-1, an Argonaute that stabilizes secondary siRNAs in the germline nuclear RNAi pathway. Further, I identify the specific endogenous piRNA that is required for efficient initiation of silencing. While the germline nuclear RNAi pathway is required for promoter-mediated *sid-1* silencing in the germline, the somatic nuclear RNAi pathway is not required for *sid-1* silencing in the soma. Instead, I find that multi-generational somatic silencing of *sid-1* specifically requires several chromatin modifying enzymes, leading to the intriguing possibility that the mechanisms of transgenerational silencing in the soma and germline are distinct.

W459 The not so simple regulation of a simple cell death. *Barbara Conradt*. LMU Munich, Planegg-Martinsried, DE.

W460 PP1β controls ZYG-1 levels to ensure precise centrosome doubling. *J. Iyer*[1], N. Peel[2], A. Naik[2], M. Dougherty[1], M. Dekker[3], K. F. O'Connell[1]. 1) NIH, Bethesda, MD; 2) The College of New Jersey, Ewing, NJ; 3) Max Planck Institute of Molecular Biology and Genetics, Dresden, Germany.

Centrosome duplication (CD) is a highly regulated process that occurs only once during each cell cycle. Deregulation of this process yields an abnormal centrosome number. This can result in aneuploidy, a hallmark of cancer cells. The nematode *C. elegans* is an excellent model system to study the process of CD because the core components of the CD pathway in *C. elegans* are conserved in humans. One such protein is the master CD kinase ZYG-1 that is absolutely essential for CD. Depleting ZYG-1 prevents CD while increasing its levels or activity causes centrosome over-duplication. Our laboratory is interested in identifying novel regulators of CD. Through our studies, we have identified the phosphatase PP1β as a biologically important and novel inhibitor of CD. PP1β acts as a molecular brake for CD as decreasing its activity causes an over-duplication of centrosomes. Western blot analysis revealed that in mutant worms with low PP1β activity, ZYG-1 protein levels are elevated. Thus, PP1β normally functions to down-regulate ZYG-1. To determine if this regulation occurs at the transcriptional, translational or post-translational level, we monitored *zyg-1* transcription and translation in mutants with low PP1β activity. In spite of an observed increase in ZYG-1 protein levels, we found that *zyg-1* transcription and translation were unaltered in worms with reduced PP1β activity. Therefore, we conclude that PP1β decreases ZYG-1 levels post-translationally by promoting its proteasomal degradation. We hypothesize that PP1β physically interacts with ZYG-1 and dephosphorylates it to promote its degradation. ZYG-1 being a low abundance protein is very difficult to immunoprecipitate from worm extracts. Therefore, we utilized an innovative approach to determine if ZYG-1 and PP1β interact *in vivo*. We tagged endogenous ZYG-1 with a Biotin Acceptor Tag (BAT) and endogenous PP1β with the *E. coli* biotin ligase (BirA) using the CRISPR technique. Indeed, we found that BAT-ZYG-1 became biotinylated only in the presence of PP1β-BirA. This suggests that ZYG-1 and PP1β physically interact *in vivo.* Thus, we

have identified the master CD kinase ZYG-1 as a novel candidate substrate of PP1β. In summary, by controlling ZYG-1 levels, PP1β ensures that only one daughter centriole forms adjacent to each mother centriole during CD. Future studies will involve determining which amino acid residues of ZYG-1 are de-phosphorylated by PP1β and the mechanism by which this leads to ZYG-1 degradation.

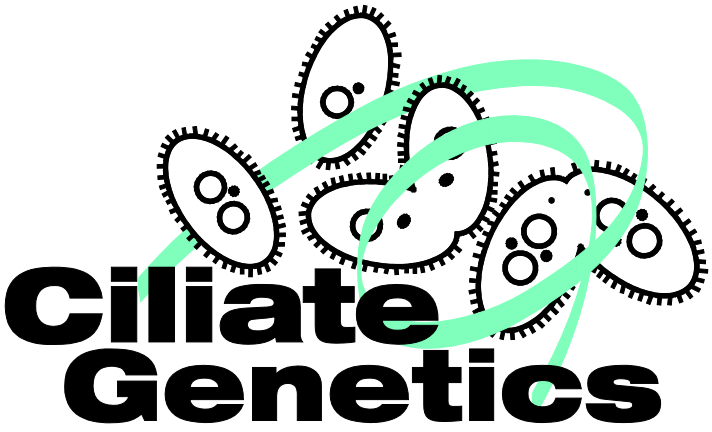
W461 Sumoylation and desumoylation in epidermal morphogenesis. *L. Broday*, A. Tsur, A. Raju, U. Bening Abu-Shach. Tel Aviv Univ, Tel Aviv, IL.

During morphogenesis junctions between epithelial cells are rapidly assembled and disassembled in order to allow cell movements and shaping of organs and tissues. We found that dynamic post-translational modifications and specifically the SUMO machinery play a role in the regulation of the flexibility of cell junctions during *Caenorhabditis elegans* epidermal morphogenesis. We identified the SUMO protease ULP-2 as a regulator of adherens junctions (AJ) assembly and show that dysregulated ULP-2 activity impairs epidermal morphogenesis in *C. elegans* embryos. The conserved cytoplasmic tail of HMR-1/E-cadherin is sumoylated and is a target of ULP-2 desumoylation activity. Coupled sumoylation and desumoylation of HMR-1 are required for its recruitment to the subapical membrane during AJ assembly and the formation of the linkages between AJs and the apical actin cytoskeleton. Sumoylation weakens HMR-1 binding to HMP-2/β-catenin. Our study provides a mechanistic link between the dynamic nature of the SUMO machinery and AJs plasticity and highlight sumoylation as a molecular switch that modulate the binding of E-cadherin to the actin cytoskeleton. We are currently studying how ULP-2 activity is regulated during epidermal morphogenesis.

W462 Conserved TRPA1-Nrf2 signaling mediates reactive alpha-dicarbonyl detoxification relevant for diabetic pathologies. *J. Chaudhuri*[1], N. Bose[1,2], J. Gong[3,4], D. Hall[1], A. Rifkind[1], D. Bhaumik[1], T. Peiris[1], M. Chamoli[1], C. Le[1], J. Liu[3], G. Lithgow[1], A. Ramanathan[1], X. Xu[4], P. Kapahi[1,2]. 1) Buck Institute for Research on Aging, Novato, USA; 2) University of California, Department of Urology, San Francisco, USA; 3) College of Life Science and Technology, Huazhong University of Science and Technology, Wuhan, China; 4) Life Sciences Institute and Department of Molecular and Integrative Physiology, University of Michigan, Ann Arbor, USA.

Chronic hyperglycemia results in the accumulation of reactive α-dicarbonyls (α-DCs), such as methylglyoxal that leads to various diabetic complications. Conventional treatment regimens for long-term diabetics focus on lowering blood glucose levels with comparatively less focus on glucose derived by-products or the α-DCs**.** α-DCs are detoxified by the evolutionarily conserved glyoxalases; however their core biochemical regulation is still not clear. Using a *Caenorhabditis elegans* model with an impaired glyoxalase (*glod-4/GLO1*), we characterized a mechanism to broadly study α-DC-related stress. *glod-4* animals display phenotypes such as hyperesthesia, neuronal damage and early mortality recapitulating diabetic neuropathy related pathologies in two weeks. Our results demonstrate TRPA-1/TRPA1 as a sensor for α-DCs, conserved between worms and mammals. Additionally, TRPA-1 activates SKN-1/Nrf2 via calcium-modulated kinase signaling that regulates the glutathione dependent (GLO1) and independent (DJ1) glyoxalases to detoxify α-DCs. Phenotypic drug screen using *C. elegans* identified podocarpic acid, a novel *C. elegans* TRPA-1 activator, that rescues the α-DC-induced pathologies both in *C. elegans* and mammalian cells. Using a combination of *C. elegans* and mammalian cells, we propose that amelioration of α-DC stress would help identify novel pharmacological leads that in principle would help overcome diabetic pathologies and associated neurodegenerative conditions like Alzheimer's, and Parkinson's disease without manipulating glucose levels.

2016 CILIATE MOLECULAR BIOLOGY MEETING



Plenary and Platform Session Abstracts

2016 Ciliate Molecular Biology Conference

SCHEDULE AT-A-GLANCE

Wednesday, July 13		
2:00pm-9:30pm	Speaker Ready Room Open	Hall of Cities - Anaheim
7:00pm-9:00pm	Scientific Session: Genomics: Genome Structure and Organization	Palms Ballroom Canary 2
9:00pm-11:00pm	Opening Mixer with Exhibits	Cypress Ballroom
Thursday, July 14		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities -Anaheim
7:45am-10:00am	Genetics and Determinants of Health Joint Plenary Session	Palms Ballroom
8:00am-4:00pm	Exhibits Open	Cypress Ballroom
9:00am-8:00pm	Demo Room: MOD (FlyBase, MGI, SGD, WormBase, Zfin) Demo Room Open	Palms Ballroom Canary 3-4
10:30am-12:30pm	Scientific Session: Programmed DNA Rearrangement I	Palms Ballroom Canary 2
12:30pm-1:30pm	Mentoring Roundtables #1	North Tower - Harbor Beach
12:30pm-1:30pm	Speaking Up for Genetics and Model Organism Research	Crystal Ballroom H
1:30pm-3:30pm	Poster Presentations 1:30pm-2:30pm: Even-numbered poster 2:30pm-3:30pm: Odd-numbered posters	Cypress Ballroom *(Posters must be removed by 1pm)*
1:30pm-3:30pm	GeneticsCareers Center and Job Fair	Cypress Ballroom 1C
4:00pm-6:00pm	Scientific Session: Evolution and Population Biology	Palms Ballroom Canary 2
4:00pm-6:00pm	Plenary Session and Workshop for Undergraduate Researchers	North Tower - Sawgrass
7:45pm-9:45pm	Scientific Session: Stability and Dynamics	Palms Ballroom Canary 2
10:00pm-11:30pm	*Science Cafe Event	Palms Ballroom Sabal
Friday, July 15		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities - Anaheim
8:00am-9:30am	Scientific Session: Programmed DNA Rearrangement II	Palms Ballroom Canary 2
8:00am-4:30pm	Exhibits Open	Cypress Ballroom
9:00am-8:00pm	Demo Room: MOD (FlyBase, MGI, SGD, WormBase, Zfin) Demo Room Open	Palms Ballroom Canary 3-4
10:00am-12:00pm	Scientific Session: Chromatin Structure & Chromatin Modification	Palms Ballroom Canary 2
12:00pm-1:30pm	*Editor's Panel Discussion and Roundtable	North Tower - Harbor Beach

** Ticketed Event*

#TAGC16

Friday, July 15 (continued)		
1:30pm-3:30pm	Poster Presentations 1:30pm-2:10pm: "A" poster authors present 2:10pm-2:50pm: "B" poster authors present 2:50pm-3:30pm: "C" poster authors present	Cypress Ballroom
1:30pm-3:30pm	GeneticsCareers Center	Cypress Ballroom 1C
2:00pm-2:45pm	GeneticsCareers Workshop - Nailing the Job Talk	Cypress Ballroom 1B
4:00pm-6:00pm	Scientific Session: Signaling Systems: Signal Transduction, Protein Secretion, and Trafficking	Palms Ballroom Canary 2
6:00pm-7:30pm	*Women in Genetics Panel and Networking	North Tower - Harbor Beach
7:30pm-9:30pm	Development and Evolution Joint Plenary Session	Palms Ballroom
Saturday, July 16		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities - Anaheim
8:00am-10:00am	Workshops: See topics and descriptions under the Workshop Section	Multiple locations
8:00am-12:00pm	Exhibits Open	Cypress Ballroom
8:00am-9:00am	Trainee Bootcamp Workshops: Session 1	North Tower
9:00am-10:00am	Trainee Bootcamp Workshops: Session 2	North Tower
10:00am-12:00pm	Poster Presentations 10:00am-11:00am: Odd-numbered posters 11:00am-12:00pm: Even-numbered posters	Cypress Ballroom
10:00am-12:00pm	GeneticsCareers Center	Cypress Ballroom 1C
10:30am-11:15am	GeneticsCareers Workshop	Cypress Ballroom 1B
12:15pm-1:45pm	*Mentoring Roundtables #2	North Tower - Harbor Beach
1:45pm-3:45pm	Scientific Session: Cell Motility: Cilia, Basal Bodies, and Tubulin	Palms Ballroom Canary 2
4:00pm-6:00pm	Scientific Session: Cell Biology, Morphogenesis, & Development	Palms Ballroom Canary 2
7:30pm-9:30pm	Scientific Session: Community Resources: Current and Future Needs	Palms Ballroom Canary 2
Sunday, July 17		
8:00am-10:00am	Scientific Session: Ciliates in the Classroom and Undergraduate Ciliate Research Symposium	Palms Ballroom Canary 2
10:30am-12:30pm	Technology and its Application Joint Plenary Session	Palms Ballroom

** Ticketed Event*

C13 Maintenance and loss of duplicated genes by dosage subfunctionalization in *Paramecium*. *J. Gout*, M. Lynch. Indiana University, Bloomington, IN, USA.

The *Paramecium aurelia* complex is a group of 15 species so similar in morphologies that they were initially believed to be only one species. The sequencing of genomes from several species belonging to the *P. aurelia* complex has revealed that the members of the *P. aurelia* complex have diverged many million years ago, following a Whole-Genome Duplication (WGD) event that took place in the common ancestor of all *P. aurelia* lineages. WGDs have been rampant in the history of eukaryotes (yeast, plants, vertebrates, etc.) and it is well established that following a WGD, most pairs of duplicated genes eventually revert to a single copy state through pseudogenization. However, some pairs retain both duplicates for long evolutionary periods and it is still unclear why some duplicates are evolutionary successful while others are rapidly lost. Here, we analyzed genomics and transcriptomics data from three *P. aurelia* species and fond that dosage constraints are major factors opposing post-WGD gene loss in *P. aurelia*. We propose a model where a majority of WGD-derived duplicates preserve their ancestral function and are retained to produce enough of the proteins performing this same ancestral function. Under this model, the expression level of individual duplicated genes can evolve neutrally as long as they maintain a roughly constant summed expression, and this allows random genetic drift towards uneven contributions of the two copies to total expression. Our analysis suggests that once a high level of imbalance is reached, which can require substantial lengths of time, the copy with the lowest expression level contributes a small enough fraction of the total expression that selection no longer opposes its loss. Extension of our analysis to yeast species sharing a common ancestral WGD yields similar results, suggesting that duplicated-gene retention for dosage constraints followed by divergence in expression level and eventual deterministic gene loss might be a universal feature of post-WGD evolution. These results also illustrate the importance of using ciliates as a model organism for studying evolution following gene and genome duplications.

C14 De-Novo sequencing of the *Paramecium tetraurelia* macronucleolar (MAC) genome using Pacific Biosciences single molecule long reads for improvement of genome assembly and annotation. *R. Woycicki*, C. Hoehener, K. Schneeberger, E. Swart, S. Bhullar, M. Nowacki. University of Bern, Bern, Bern, CH.

De-novo sequencing of the *Paramecium tetraurelia* MAC genome, set previously its size to be of 72 Mbp. Since discovery of NGS methods the *Paramecium* MAC genome is routinely sequenced for mapping proposes during the course of studying the massive whole genome rearrangements system. Our recent estimation of the genome size made with Illumina 2x125 PE data (coverage > 100x) using the PreQC module from the String Graph Assembler software, showed that the actual MAC genome size can be about 20 percent larger. Unlike the first and second generation sequencing methods, Pacific Biosciences (PacBio) sequencing shows more equal coverage along the genome. No template amplification eliminates bias towards cloned/amplified sequences before the actual sequencing. Taking into consideration the above as well as the very long PacBio reads, we have chosen this system to de-novo sequence and assemble the *Paramecium tetraurelia* MAC genome with the goal of improvement both the genome assembly as well as the genes annotation.

Using the newest PacBio P6-C4 chemistry and 13 SMRT cells, the sequencing resulted in more than 250x coverage of the *Paramecium tetraurelia* strain 51 mating type 7 MAC genome. The reads error correction and assembly was conducted using first the PBcR pipeline from Celera Assembler ver. 8.3rc2 and later using Canu software (v1.0/v1.1).

Our preliminary de-novo assembly allowed us to map to it more shotgun Illumina and Sanger genomic, cDNA and MAC matching 25nt smallRNA reads, than to the reference 51 strain assembly. Based on cDNA mapping we estimate that our current assembly may have a few hundred more new genes.

We will present the current state of genome assembly and annotation which aims to reconstruct a more complete genome.

C15 Comparative genomics in the ciliate genus Paramecium. *Georgi Marinov*, Thomas G. Doak, Michael Lynch. Indiana University, Bloomington, IN.

The *Paramecium* genus provides a unique system for studying the effects of gene and genome duplication on organismal phenotype. It contains a number of distinct morphospecies together with numerous cryptic species, morphologically indistinguishable but biologically isolated from each other. The most famous such group is the *P. aurelia* species complex, consisting of ~15 distinct species, which is also remarkable for having undergone two whole-genome duplication (WGD) events not shared with other members of the *Paramecium* genus prior to its diversification. *Paramecium* is thus of great importance for our understanding of gene duplication and WGD events, their phenotypic effects, and the factors influencing the evolution of orthologous and paralogous genes and regulatory sequences. We address these issues by presenting a comprehensive comparative genomic analysis of members of the *P. aurelia* species complex together with several *Paramecium* species outside of the *aurelia* group.

C16 Programmed retention of germline-limited genes in *Oxytricha trifallax*. *Richard V. Miller*[1], Derek M. Clay[1], Laura F. Landweber[1,2]. 1) Princeton University, Princeton, NJ; 2) Columbia University Medical Center, New York, NY.

One of the defining characteristics of ciliates is nuclear dimorphism: two types of nuclei with distinct genome architectures exist within one cell. In *Oxytricha trifallax*, one nucleus contains a fragmented and scrambled germline copy of the somatic genome. During mating, a haploid germline nucleus transfers between cells. After fertilization, a zygotic germline nucleus matures into a new somatic nucleus by undergoing a process of DNA elimination and rearrangement. In addition to fragments of coding sequences that are retained in the somatic genome and noncoding sequences that are eliminated, 810 recently discovered germline-restricted genes also reside in the germline genome and are eliminated during development. These genes are only transcribed during the process of DNA elimination and rearrangement, and their elimination during development of the somatic genome may constitute a mechanism of developmental gene regulation. I have shown that

microinjection of RNA matching the sequences of germline-restricted genes reprograms the cell to retain these genes in a heritable manner. Furthermore, it appears that retained germline genes are transcribed outside of their normal developmental window. These data support a model in which germline-restricted genes are relegated to the germline nucleus to ensure that they are only expressed during the sexual cycle.

C17 Cell Cycle Transcriptome Analysis in the Binucleated Ciliate, *Tetrahymena thermophila*. *L. Zhang*[1*], M. Cervantes[1], K. Kronganti[1], X. Jie[2], W. Miao[2], G. M. Kapler[1]. 1) Department of Molecular and Cellular Medicine, Texas A&M Health Science Center, College Station, TX; 2) Institute of Hydrobiology, Chinese Academy of Sciences,Wuhan, China.

As a bi-nucleated eukaryote, *Tetrahymena thermophila* has two distinct nuclear cycles within each vegetative cell cycle. Rather than a mononucleate G1-S-G2-Mitosis cell cycle, the somatic nuclear cycle of Tetrahymena progresses through G1-S_{mac}-G2-Amitosis, while the germline nuclear cycle is S_{mic}-G2-M-S_{mic}. Furthermore, in contrast to mononucleated organisms, mitosis is not temporally coupled to cytokinesis. Gene expression data could reveal transcriptional programs critical to processes during the cell cycle. By use of centrifugal elutriation to synchronize the vegetative cell cycle, along with RNAseq and EdU labeling, we have begun to elucidate the transcriptional program across the vegetative cell cycle. At 30-minute intervals, we have deployed RNAseq to identify all genes that encode cell cycle regulated transcripts. We have also subjected elutriated cells to EdU labeling to assess mic and mac DNA synthesis, and in conjunction with other cytological markers have assessed synchrony and assign time points to stages of the cell cycle. What we have found is that of the ~27000 annotated genes (TGD.org), nearly 4500 (16%) exhibit a dynamic regulation in mRNA levels of a two-fold change above background. Of those 4500 genes, 2,166 (48%) map to an associated gene ontology (GO) term. At our most stringent criteria for cycling – above twice the median expression of all genes (around 50 counts after normalization) and at least a 4-fold change in expression between 2 time points – we find roughly 400 genes of which 139 (35%) map to associated GO terms. 69 (49%) of the GO terms assigned to our most stringent criteria fall in pathways involved in DNA replication, chromosome organization and microtubule anchoring. Examples of genes within these pathways that demonstrate a 4-fold change in expression include TPB1, a PiggyBack-like protein, DNA licensing factor MCM2, and separase protein ESP1. In regards to temporal regulation of mRNA production, we have found that mRNA levels of replicative genes and certain histone modifiers are up-regulated coordinately at the G1/S border and during S phase of the cell cycle. As for genes involved in cell cycle progression – better known as cyclin genes – we see that 13 of the 26 show dramatic regulation in mRNA levels and meet our criteria for cycling. Some cyclin profiles may suggest their involvement mic –or mac-specific events, warranting further investigation. The wide breath of pathways and genes covered by our data suggest its usefulness to the research community.

C18 RNA-seq analysis of stress response to silver nanoparticles in *Tetrahymena thermophila*. *A. Piersanti*[1], K. Juganson[2], W. Wei[3], J. Zhang[3], Z. Zhao[3], S. Pucciarelli[1], C. Miceli[1], W. Miao[3]. 1) School of Biosciences and Veterinary Medicine, University of Camerino, Italy; 2) Laboratory of Environmental Toxicology, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia; 3) Institute of Hydrobiology, Chinese Academy of Sciences, Wuhan, China.

Currently, silver nanoparticles are increasingly used as biocides in various consumer products and if released in the environment they can affect non-target organisms. Nanoparticles are defined as particles with at least one dimension between 1 and 100 nm. The specific surface area increases in reversal proportion to the particle size; thus, the smaller the particle, the greater the proportion of atoms that lay close to or at the surface resulting in higher reactivity of the particle. These properties, which make nanomaterials more efficient in industrial applications, might make them also more harmful to living organisms since they could be able to penetrate physiological barriers, travel throughout the body and interact with subcellular structures. Therefore, understanding the toxicity mechanisms is crucial for both the design of more efficient nano-antimicrobials and, at the same time, for the design of nanomaterials that are biologically and/or environmentally benign throughout their life-cycle.

Tetrahymena thermophila has been largely investigated and functional genomic databases are available. Therefore*, T. thermophila* provides an optimal model system for studying molecular bases of environmental responses, since molecular data obtained in different environmental conditions can be easily compared. We recently used *T. thermophila* to elucidate the environmental effects of silver nanoparticles by analysing *T. thermophila*'s gene expression profile by RNA-seq after exposure to collargol (protein-stabilized silver nanoparticles) and comparing with the effect of the soluble silver salt, $AgNO_3$. In order to see the effects of these substances in viable cells, only sub-lethal concentrations are used in gene expression studies. We tested two different toxicant concentrations at two time points, for 2 and 24 hours.

The experimental sequences are compared with the control to evaluate quantitatively the inhibition or increase of gene expression due to nanoparticles or silver ions. Then gene set enrichment is performed.

Some processes are targets of both toxicants. In addition to many similarities in affected genes, some effects were different for soluble silver ion with respect to collargol. We found that genes involved in mRNA splicing and translation processes appear differentially expressed only in collargol treated samples.

This research provides evidence that silver nanoparticles might be toxic due to combined effects of soluble silver ions released from the particles and the particles themselves.

C19 Preliminary analysis on genome and transcriptome data of two species of karyorelictids, *Loxodes* sp. and Trachelocercidae sp. (Ciliophora, Karyorelictea). *Y. Yan*[1,2], X. Maurer-Alcalá[2,3], A. Rogers[2], L. Katz[2,3]. 1) Ocean University of China, Qingdao, China; 2) Smith College, Northampton, MA, US; 3) University of Massachusetts Amherst, Amherst, MA, US.

Karyorelictea are an understudied class of ciliates characterized by the presence of postciliodesma fibers and non-dividing somatic macronuclei. Karyorelictids have both somatic macronucleus and transcriptionally silent germline micronucleus like other ciliates. However,

during vegetative growth, their 'paradiploid' macronuclei are unable to divide and their number of macronuclei can only be reestablished by division and differentiation from germline micronuclei (Raikov, 1985). All other ciliate classes have polyploid macronuclei dividing through amitosis (Raikov, 1985). Since the majority of Karyorelictids are currently uncultivable, few data are available compared to other groups of ciliates (i.e. only 72 nucleotide sequences including environmental samples and six protein sequences are in Genbank); and only a limited number of studies focusing on the karyorelictean nuclei have been published (Bobyleva et al., 1980; Raikov, 1963, 1972, 1989; Raikov and Karadzhan, 1985). Recently, we collected two karyorelictean species, ***Loxodes*** sp. and Trachelocercidae sp., to characterize genome features through single cell whole genome amplification and whole transcriptome amplification. We are currently analyzing over 39 million Illumina reads from these taxa. After the removal of bacterial contaminants and poor quality reads, we are assembling the protein-coding genes from these taxa and performing pilot analyses of genome structure.

C20 Genome Rearrangement and Organization in *Oxytricha*: A Complex Epigenome. *Laura Landweber*[1,2], Jaspreet Khurana[1,2], Leslie Beh[2], Kelsi Lindblad[2], Xiao Chen[2], Robert Sebra[3]. 1) Columbia University, New York, NY; 2) Princeton University, Princeton, NJ; 3) Icahn School of Medicine at Mount Sinai, New York, NY.

The ciliate *Oxytricha* possesses a dynamic pair of genomes. Massive DNA rearrangements produce a highly fragmented but functional somatic genome from a complex germline genome. This process eliminates nearly all noncoding DNA, including transposons, and rearranges over 225,000 short DNA segments to produce a mature, somatic genome containing over 16,000 gene-sized "nanochromosomes." In the precursor germline genome, the shattered segments of different genes often interweave with each other, frequently overlap and may combinatorially assemble. Noncoding RNAs guide the entire process of genome rearrangement, but DNA methylation of both cytosine (m5C and hm5C) and adenosine (m6A) also influence genome organization. We previously described a class of 27nt piRNAs that provide the critical information to mark and protect the retained DNA segments of the genome. We recently identified new classes of small RNAs involved in different aspects of genome regulation. Maternally-inherited, long RNA transcripts provide templates for genome remodeling and RNA-guided DNA repair, but they also regulate gene dosage and chromosome copy number, possibly together with a new class of small RNAs. Overall, *Oxytricha*'s elaborate epigenome, assembled and maintained through complex interacting networks of both long and small non-coding RNAs, encapsulates an RNA-driven world packaged in a modern cell. The mechanism for all of these dynamic actions bypasses traditional pathways of inheritance, hinting at the power of RNA molecules and DNA modifications to sculpt genomic information.

C21 Novel genetic manipulation approaches to investigate development-specific genes in *Oxytricha trifallax*. *D. M. Clay*[1], L. F. Landweber[1,2]. 1) Princeton University, Princeton, NJ; 2) Columbia University, New York, NY.

Oxytricha trifallax is a stichotrich which transforms a micronucleus into a macronucleus during sexual development by excising and rearranging its DNA. During this genomic rearrangement, more than 90% of the DNA sequence in the micronuclear chromosomes is deleted. The remaining sequences are converted into ~16,000 nanochromosomes with average length of 3 kb, forming the macronucleus. Development of the new macronucleus from a copy of the zygotic micronucleus requires a suite of non-coding RNAs. In *Oxytricha trifallax*, long RNA templates, together with 27-nucleotide Piwi associated RNAs, guide genome rearrangements. By exploiting these pathways, somatic gene knockouts in *Oxytricha* have been developed. In this study we investigated two highly expressed early sexual development-specific genes, Alba-like 1 and Alba-like 2, which encode Alba domain containing proteins. Alba domains are known to be nuclei acid binding proteins and are involved in translation regulation in *Trypansoma brucei* (Mani *et al*., 2011) and *Plasmodium falciparum* (Vembar *et al*., 2015). Both Alba-like 1 and Alba-like 2 genes were identified as co-precipitates of long dsRNA, possibly the RNA templates, in early sexual development. Knockouts of both genes were developed through exploiting the genomic rearrangement pathways of *Oxytricha* via different approaches. The introduction of artificial piRNAs programs the retention of normally eliminated sequences, which permits retention of DNA sequences that interrupt open reading frames. Another approach is the introduction of synthetic DNA templates which sometimes induces deletion of the targeted nanochromosome. For both genes, the knockout cell lines are viable during vegetative, asexual growth but unable to complete sexual development, with Alba-like 1 being trans-lethal when mated to wild type. To further probe the functions of these target genes, tagged proteins were generated using artificial nanochromosomes injected into the macronucleus of vegetative cells. This transformation approach results in artificial chromosomes that are maintained throughout the asexual life cycle at high copy number and show expression patterns that faithfully recapitulate their native counterparts and permit purification of the tagged proteins. Together, these experiments have increased the utility of *Oxytricha trifallax* as a model system for genetics.

C22 The prevalence of paralogous macronuclear DNA fragments aid in the formation of scrambled genes in *Oxytricha trifallax*. *J. Burns*[1,2], M. Saito[2], N. Jonoska[2], L. F. Landweber[1]. 1) Princeton Univ., Princeton, NJ; 2) USF, Tampa, FL.

A ciliated protozoa undergoes programmed genome rearrangements during nuclear development, forming a transcriptionally active somatic macronucleus from a copy of its germline micronucleus. In *O. trifallax*, this nuclear transition involves an RNA-mediated excision of 90% of the germline genome, after which, the remaining 225,000 DNA fragments are amplified and reorganized into gene-sized nanochromosomes via RNA templates. Early analysis of the sequenced *O. trifallax* genomes revealed instances of alternative fragmentation of longer chromosomes into shorter ones, and alternative processing of a single loci of conserved micronuclear material to form a variety of macronuclear genes. In this study we observe that the micronuclear genome of *O. trifallax* contains an abundance of paralogous macronuclear segments -- at varying levels of degeneration -- that contribute to the genetic variation of the micronuclear genome, promote the evolution of new macronuclear genes, and provide the means for a gene to become scrambled in the germline genome.

C23 Domesticated *piggyBac* transposases and DNA repair factors work hand in hand during programmed rearrangements in *Paramecium*. *Mireille Betermier*[1], Julien Bischerour[1], Simran Bhullar[2,3], Vinciane Régnier[1], Nathalie Mathy[1], Cyril Denby Wilkes[1], Olivier Arnaiz[1], Estienne Swart[2], Arthur Abello[1], Marc Guérineau[1], Linda Sperling[1], Mariusz Nowacki[2]. 1) I2BC, CNRS, CEA, Univ. Paris Sud, Gif-sur-Yvette, FR; 2) Inst. of Cell Biology, Univ. Bern, Bern, CH; 3) IBENS, Paris, FR.

Because of their nuclear dimorphism, ciliates constitute unique unicellular models for the study of the molecular mechanisms involved in programmed DNA elimination during somatic differentiation. During development of the macronucleus (MAC) in *Paramecium tetraurelia*, ~30% of the germline DNA is eliminated from the somatic genome. Eliminated sequences include ~45,000 short, single-copy Internal Eliminated Sequences (IESs), which are excised through a highly precise "cut-and-close" mechanism related to DNA transposition. PiggyMac (Pgm), a catalytic active domesticated piggyBac transposase, is essential for the introduction of initiating DNA double-strand breaks at IES ends. The DNA double-strand break repair proteins Ku70/Ku80 interact with Pgm and are required for DNA cleavage at IES ends, ensures tight coupling between DNA cleavage and repair. Because IESs do not carry a clearly conserved sequence motif that could be recognized specifically by the excision machinery, one major issue is whether other partners are required to target Pgm to IES ends.

We recently discovered that nine additional Pgm-like (PgmL) proteins are encoded by the MAC genome. *PGML* genes group in five families of whole-genome duplication (WGD) ohnologs. In contrast to Pgm, PgmLs do not harbor a conspicuous DDD catalytic triad, suggesting that they may not have retained full catalytic activity. However, high-throughput RNA sequencing revealed that all *PGML* genes are transcribed specifically during MAC development, and fluorescence microscopy data indicated that all PgmL proteins localize in the developing new MAC. Systematic RNAi experiments, and a genome-wide survey of IES retention in depleted cells, established that each PgmL family is essential for IES excision. Using a heterologous protein expression system, we demonstrated that PgmLs can interact with each other and with Pgm in cell extracts. However, the nuclear localization of each PgmL family is differentially affected upon RNAi-mediated inactivation of other *PGML* genes. Our results indicate that Pgm acts within a highly ordered multi-component protein complex to catalyze programmed DNA elimination.

C24 SDCP, a novel Paramecium protein involved in macronuclear development during autogamy. *A. Singh*[1,2], E. Swart[1], S. Gisler[1], M. Nowacki[1]. 1) IZB, University of Bern, Bern, CH; 2) GCB, University of Bern, Bern, CH.

In ciliates, massive genome reorganization occurs during autogamy where superfluous DNA such as Internal Eliminated Sequences (IESs), transposons, minisatellites and other repetitive sequences are eliminated from the developing macronucleus producing a streamlined functional somatic genome. Here we describe our current analyses of a novel *Paramecium tetraurelia* protein, *SDCP*, which is significantly differentially expressed during autogamy. *SDCP* contains an ATPase, a helicase domain, a SANT domain and a SLIDE domain. This architecture is characteristic of the conserved ISWI protein family. The domains of ISWI proteins are known to play multiple roles, regulating transcription, chromosome organization and DNA replication. This makes *SDCP* an interesting protein to study its putative role in the genome reorganization during sexual reproduction (autogamy).

Knockdown of SDCP during autogamy in *Paramecium tetraurelia* is lethal and affects both precise and imprecise DNA excision leading to the retention of maternally and non-maternally controlled IESs, and transposons. MAC genome sequencing data following *SDCP* knockdown shows substantial retention of IESs and a modest correlation between IESs retained following either *Nowa1* or *TFIIS4* silencing, two other genes involved in IES excision (Nowacki, 2005 & Maliszewska-Olejniczak, 2015). SDCP knockdown leads to similar IES end base frequency variation relative to IES retention in a similar manner to that seen for the other genes (Swart & Denby Wilkes, 2014). Interestingly, IES retention scores seem to peak at a regular base length interval corresponding to the size of the nucleosomes. Since the C-terminal of the protein contains a SLIDE domain, that is known to regulate ATP-dependent repositioning of the nucleosomes, we wished to determine, firstly whether SDCP is involved in nucleosome positioning, and secondly if the nucleosome position around an IES is important for its precise excision. To assess these possible roles for SDCP, we are therefore sequencing nucleosome-bound DNA from post-autogamous cultures.

C25 A mutagenesis screen based on mating-type switch reveals a small subset of IESs enriched in a 5-bp motif. *S. Bhullar*[1], O. Arnaiz[3], C. Denby Wilkes[3], G. Pellerin[1], S. Malinsky[1], L. Sperling[3], M. Nowacki[2], E. Meyer[1]. 1) Institute de Biologie l'Ecole Normale Superieure, 46 rue d'Ulm, 75005 Paris, France; 2) Institute of Cell Biology, University of Bern, Baltzerstrasse 4, 3012 Bern, CH; 3) nstitute of Integrative Biology of the Cell (I2BC), UMR 9198 CNRS CEA Université Paris-Sud, Gif-sur-Yvette, France.

Genome rearrangements during macronuclear development in *Paramecium tetraurelia* have been proposed to be guided by meiosis-specific small RNAs, called scnRNAs, which are produced from micronuclear transcripts by the Dicer-like proteins Dcl2 and Dcl3. ScnRNAs are likely bound by the Piwi proteins Ptiwi01 and Ptiwi09 and are required to target the excision of a subset of MIC-specific sequences in the developing MAC, including maternally controlled IESs: silencing of both Dicer-like or both Piwi genes during autogamy results in genome rearrangement defects and in cell death. To obtain viable mutants in scnRNA-pathway genes, we designed a mutagenesis screen based on mating type reversal, which relies on the hypersensitivity of the mtA promoter IES to the slightest perturbation of the scnRNA pathway. Mating type O is normally determined during MAC development by the excision of the promoter of the *mtA* gene as an IES. This excision event is impaired by the silencing of a single gene from the Dcl2/Dcl3 or Ptiwi01/Ptiwi09 pairs, which results in mating type E viable progeny, whereas other IESs are hardly affected. Furthermore, the promoter-retaining version of the mtA gene is 'dominant' over the promoter-excised version, since it allows expression of the gene, while retention of intragenic IESs results in non-functional genes. Thus, screening populations of mutagenized O cells for E-expressing progeny should allow us to recover non-lethal mutations that only partially impair the scnRNA pathway, such as null alleles of genes with redundant ohnologs or hypomorphic alleles of essential genes. This scheme allowed us to isolate 2 mutants: one is a null allele of a developmentally regulated zinc finger protein with a WGD1 ohnolog, called *mtG*, and the other is a mis-sense mutation in Ptiwi09. An mtG-GFP fusion protein was shown to localize in the new MAC, with an initially punctate pattern. As development proceeds, mtG-GFP progressively concentrates at a single spot in the DNA-poor region of the MAC, as does the heterochromatin mark, H3K9me3. RNAi-mediated silencing of

mtG and/or its ohnolog during autogamy of wild-type O cells impaired excision of the *mtA* promoter and caused progeny to switch to mating type E. In addition, resequencing of the MAC genome showed that a very small subset of ~100 IESs are retained in these conditions. These IESs are significantly enriched in a 5-bp motif, GCTAA, and have a specific size range. Preliminary analysis of *mtG* function in the sibling species *P. octaurelia* suggested that orthologous IESs also require *mtG* for excision, but only when the GCTAA motifs are conserved. I will discuss the possible mechanisms and biological significance of *mtG*-dependent IES excision.

C26 Transposable elements as vehicles of gene movement and duplication within and between eukaryotes. *Ellen Pritham*[1], Komal Vadnagara[2], Jainy Thomas[1]. 1) University of Utah, Salt Lake City, UT; 2) MD Anderson, Houston, TX.

Transposable elements are mutagens that can contribute directly and indirectly to genetic innovation. In bacteria, transposable elements carrying genes involved in cellular function such as antibiotic resistance, catabolism, and pathogenicity are commonly horizontally transferred. Contrary to their bacterial counterparts, eukaryotic transposable elements are not known to traffic cellular genes between species. Here we provide evidence that many different superfamilies of eukaryotic transposable elements are actively transducing and transporting cellular genes across species boundaries. Families of *Crypton*, *Helitron, Mutator, PiF-Harbinger and PiggyBac,* identified from the genome of the eukaryotic phyto-pathogenic microbe, *Phytophthora infestans* carry cellular genes, in addition to the genes encoding transposase (called supercharged in this study (SCTE). The supercharged genes are predicted to be involved in epigenetic gene regulation or pathogenicity and expressed during plant infection. We show that large gene families were spawned via SCTE transposition. These superfamilies are predominantly found in the dynamic genome locale populated by host recognition and infection genes as well as genes necessary for growth, *in planta*. Indeed, SCTE transposition facilitated the seeding of this region with genes typically found in more constrained locations. Finally, we present compelling evidence that transposable elements are transporting genes horizontally between *Phytophthora* species. Our results demonstrate that eukaryotic transposable elements, like their bacterial counterparts, are vehicles of gene movement both within and between genomes.

C27 Evolution of internal eliminated sequences in *Paramecium*. *Diamantis Sellis*[1], Frédéric Guérin[2], Olivier Arnaiz[5], Walker Pett[1], Nicole Boggetto[2], Sascha Krenek[3], Thomas Berendonk[3], Arnaud Couloux[4], Jean-Marc Aury[4], Karine Labadie[4], Sophie Malinsky[6], Simran Bhullar[6], Eric Meyer[6], Linda Sperling[5], Sandra Duharcourt[2], Laurent Duret[1]. 1) Université Lyon 1, CNRS, UMR 5558, LBBE, Villeurbanne, France; 2) Institut Jacques Monod, CNRS, UMR 7592, Sorbonne Paris Cité, Paris, France; 3) TU Dresden, Institute of Hydrobiology, Dresden, Germany; 4) Commissariat à l'Energie Atomique (CEA), Institut de Génomique (IG), Genoscope, Evry, France; 5) Institute of Integrative Biology of the Cell, UMR9198 CNRS CEA U Paris-Sud,91198 Gif-sur-Yvette, France; 6) Ecole Normale Supérieure, Institut de Biologie de l'ENS, IBENS, Paris, France.

The genome of *Paramecium* undergoes a remarkable reorganization during the development of the macronucleus. Tens of thousands of mostly short sequences are interspersed in the micronuclear genome, often interrupting protein reading frames. During the macronuclear development, these internal eliminated sequences (IESs) are precisely excised and thus the macronuclear genes are fully functional. The role, if any, of IESs, their evolutionary history and dynamics as well as the molecular mechanism(s) involved in their excision are still far from resolved. As a first step towards exploring these questions we here performed a large scale systematic reconstruction of the evolutionary history of IESs in *Paramecium*. We focused on 7 species from the aurelia species complex and used *P. caudatum* as an outgroup. We sequenced the micronuclear and, when not available, the macronuclear genomes of each species and annotated genes and IESs. We specifically focused on conserved genes that can be aligned across species in order to find homologous IESs. We inferred the phylogenies of each gene family and reconciled the resulting gene trees with the species tree. Using a Bayesian approach we inferred the ancestral states of presence and absence for each IES. The result is an unprecedented detailed description of the evolutionary history of tens of thousands of IESs. Preliminary results validate previous models of IES evolution. We find that there was a wave of insertion of IESs after the split of the aurelia species complex from *P. caudatum* and subsequently the rate of gain and loss of IESs was significantly reduced. Our detailed description of IES evolutionary history also enables us to compare the age of acquisition of different IESs with various genomic properties. For example we find that recently inserted IESs are on average longer. We believe that our results will fuel further studies to test models and gain new insights on the molecular mechanisms of genomic rearrangements in the developing macronucleus.

C28 Population genomics of *Paramecium* species. *P. Johri*[1], T. G. Doak[1], S. Krenek[2], G. K. Marinov[1], M. Lynch[1]. 1) Indiana University, Bloomington, IN; 2) Institute of Hydrobiology, Technische Universität Dresden, Dresden, Germany.

Population-genomic analyses are essential to understanding factors shaping genomic variation and revealing lineage-specific sequence constraints and adaptation. The dearth of such analyses for unicellular eukaryotes prompted us to assess variation in *Paramecium*, one of the most well-studied ciliate genera. The a*urelia* complex consists of ~15 morphologically indistinguishable species that diverged subsequent to two rounds of whole-genome duplications (WGDs), perhaps as long as 320 MYA, and are well known for their streamlined genomes and extremely short introns. We examine patterns of polymorphism by sequencing whole genomes of 10-13 worldwide isolates of each of three species belonging to the *Paramecium aurelia* complex: *P. tetraurelia*, *P. biaurelia*, *P. sexuarelia,* and two outgroup species that do not share the WGDs: *P. caudatum* and *P. multimicronucleatum*. An apparent absence of strong global geographic population structure suggests continuous or recent dispersal of *Paramecium* over long distances. Introns and intergenic regions are highly constrained relative to 4-fold degenerate sites, more so in species with smaller intergenic regions. Nuclear genomic diversity in the intergenic regions is reduced for ~100-150 bp, both upstream and downstream of genes, suggesting the presence of densely packed regulatory modules. The beginning and end (~70-100 bp) of protein-coding genes are more constrained than the rest of the gene. Comparison of sequence variation at non-synonymous and synonymous sites allows identification of possible candidates of duplicate genes that might be undergoing non-functionalization and provides insights

into differential evolutionary constraints on single-copy versus multi-copy genes. This study serves as a first attempt at a population-genomic analysis in *Paramecium*, and provides an excellent resource for future studies in evolutionary and functional genetics in ciliates.

C29 Transcriptome analysis in the Antarctic ciliate Euplotes focardii: molecular basis of cold adaptation and insights regarding the potential impact of climate change. *Cristina Miceli*, Sandra Pucciarelli, Patrizia Ballarini, Angela Piersanti, Kesava Pryan Ramasamy. School of Biosciences and Veterinary Medicine, University of Camerino, IT.

Ciliates provide optimal model systems to study environmental adaptation. Comparative transcriptome analysis of *Euplotes focardii*, a strictly psychrophilic ciliate isolated from Antarctic seawater, and the mesophilic congeneric species *E. crassus* revealed that in *E. focardii* the majority of the expressed genes code for proteins involved in oxidoreductase activity, as reported for Antarctic fishes and krill. These results confirm that a major problem of Antarctic marine organisms is to cope with increased O_2 solubility at low temperatures. They also suggest that an increased defense against oxidative stress likely provides an important evolutionary feature that allowed the adaptation of Antarctic organisms in their oxygen-rich environment. Gene ontology annotation also revealed that many of the transcripts encoded proteins involved in maintenance of protein homeostasis (e.g., chaperones). Quantitative PCR showed that expression of *Hsp70* genes was induced when *E. focardii* cells were subjected to oxidative stress, whereas thermal stress did not cause induction. These results argue that *E. focardii* in its current environment is well protected against reactive oxygen species and are consistent with prior reports of constitutive *Hsp70* expression as a defense against cold-induced protein denaturation. *E. focardii* appears to be poised to cope with the oxidative challenge that is likely to accompany oceanic warming over the next century, but the absence of a temperature-inducible chaperone response may place its proteome at risk.

The comparative analysis of the *Euplotes* species also revealed a rapid evolution and unusual plasticity of the programmed +1 ribosomal frameshifting, a process that allows the change of the reading frame during translation. This process appears pervasive in *Euplotes* as it affects decoding of over 3,000 genes in these genomes and it is not conserved in the affected genes of the two species. In addition, evidence for +2 frameshifting appeared from the analysis.

We are currently setting up reverse genetics in *E. focardii* in order to have a better understanding of the function of some genes that are expressed only in the cold adapted species.

C30 Comparison of adaptive mechanism between sexual and asexual reproduction in *Tetrahymena thermophila* based on the experimental evolutionary genomics. *W. Miao*, G. Wang, K. Chen, W. Yang, J. Xiong. Institute of Hydrobiology, Chinese Academy of Sciences, Wuhan, Hubei, CN.

The evolution and maintenance of sex is an important problem in evolutionary biology. The advantage of sexual reproduction was thought that it increases the rate of adaptation to the novel environment comparing to the asexual reproduction, but the molecular basis of this adaptive advantage and the similarities/differences between sexual and asexual reproduction are still unclear. *Tetrahymena thermophila*, as a classical unicellular model organism, has made outstanding contributions to the discovery of foundational biology, such as telomere, telomerase and RNA self-splicing. Using its advantages including possessing sexual and asexual stages during its life cycle, culture in the lab, complete genomic and transcriptomic database and techniques of omics and bioinformatics, we dynamically detect the changes of DNA, transcriptional regulation and genome organization during the continuous culture in the lab. Five parallel cell lines were set up. Currently, 1100 asexual fissions and 11 times sexual reproduction had been completed. The fitness tests (growth rate) indicated sexual populations grew significantly faster than asexual populations. Moreover, base on the re-sequencing genome/transcriptome data, we found sexual populations can produce much more genetic variation and accumulate more beneficial mutations than those of asexual populations. In addition, as for sexual group, all the populations had losed mating ability after at most six rounds of sexual reproduction because of the purification of mating types, which resulted in them switching from sexual reproduction to asexual reproduction. Followed by this switching, the fixation of beneficial mutations produced by sex was completed in short 100-200 fissions through asexual reproduction.

C31 Diversities of endosymbiotic *Rickettsia* in the fish parasite *Ichthyophthirius multifiliis*. *Kassandra Ernestine Zaila*[1*], Thomas G. Doak[2,7], Hannah Ellerbrock[1], Che-Huang Tung[3], Mauricio L. Martins[4], Daniel Kolbin[5], Meng-Chao Yao[6], Donna M. Cassidy-Hanley[5], Theodore G. Clark[5], Wei-Jen Chang[1,6]. 1) Hamilton College, Clinton , NY; 2) Indiana University, Bloomington, IN; 3) National Chyai University, Chyai City 60004, Taiwan; 4) College of Veterinary Medicine, Cornell University, Ithaca, NY; 5) Universidade Federal de Santa Catarina, 88040-900, Florianópolis, Santa Catarina, Brazil; 6) Academia Sinica, Taipei 115, Taiwan; 7) National Center for Genome Assembly Support, Indiana University.

Although the presence of endosymbiotic bacteria—specifically *Rickettsia*—have been reported in the ciliated protozoan *Ichthyophthirius multifiliis*, an obligate parasite that infects freshwater fish, it remains unclear whether these bacteria are present in most, if not all, isolates of *I. multifiliis*. In this study we report identification of these endosymbiotic bacteria in 18 different isolates of *I. multifiliis*, from three distinct geographical regions worldwide (Brazil, Taiwan, and United States). In three isolates (Ark11, Ark12, and G15) the presence of endosymbiotic bacteria were determined by deep sequencing, and in the remaining 15 isolates bacteria were detected by PCR amplification of conserved regions of the bacterial 16S rDNA genes. All *Ichthyophthirius* isolates appear to contain at least one rickettsial rDNA sequence. This ubiquity suggests that *I. multifiliis*—which has a very reduced genome— may be dependent on this endosymbiotic relationship. Results derived from phylogenetic analyses based on rickettsial rDNA sequences show that the rickettsial bacteria can be clustered into four groups. Some *I. multifiliis* isolates—particularly those collected from pet stores—were infected by multiple groups of rickettsial bacteria, suggesting that the association between *Rickettsia* and *I. multifiliis* is more dynamic than previously thought. Our results also support the hypothesis that

endosymbiotic *Rickettsia* is transmitted both vertically and horizontally, although mechanisms accounted for horizontal transfer remain unknown.

C32 Genetic and epigenetic control of DNA replication in *Tetrahymena thermophila*. *Geoffrey Kapler*[1], Xiangzhou Meng[1], Chunxiao Ge[1], Yifan Liu[2], Shan Gao[3]. 1) Texas A&M University, College Station, TX; 2) University of Michigan, Ann Arbor, MI; 3) Ocean University of China, Qingdao, China.

The 21 kb *T. thermophila* ribosomal DNA (rDNA) minichromosome initiates DNA replication once per cell cycle during vegetative growth from origins that reside in the 5' non-transcribed spacer (5' NTS). Using Q-PCR, we show that the rDNA is replicated by two distinct modes during macronuclear development- locus-specific gene amplification, and genome-wide endoreplication. 5' NTS origins mediate the initial wave of replication- amplification from 2C to 800C in starved mating cultures. This occurs in a restricted temporal window, concurrent with genome-wide endoreplication of non-rDNA macronuclear chromosomes from 2C to 8C. Upon re-feeding, the rDNA is no longer selectively amplified. Instead, it is endoreplicated to ~9000C along with the remainder of the genome, which achieves a copy number of ~45C. ORC protein levels are reduced during the second wave of DNA synthesis and known origins in the rDNA 5' NTS are frequently bypassed. Aberrantly migrating rDNA replication intermediates (RIs) form at this time; their migration in 2D gels is consistent with the accumulation of stable RNA-DNA hybrids in the 5' NTS. These RIs are indistinguishable from intermediates generated in a vegetative TXR1 knockout mutant strain, defective in histone H3K27 monomethylation.

To explore the possible relationship between H3K27me1 and endoreplication, the average inter-origin distance (IOD) was determined by DNA fiber analysis. This genome-wide approach revealed significant differences in replication initiation in endoreplicating wild type cells and vegetative TXR1 mutants. Despite the down-regulation of Orc1p in endoreplicating mated/re-fed cells, IOD decreased. Paradoxically, more initiation events occur when ORC levels are reduced. In contrast, the IOD increased in the vegetative TXR1 knockout mutant. Thus, although the formation of aberrant RIs is conserved, the mechanism underlying their biogenesis may differ. Finally, RNA-Seq revealed that TXR1 mRNA levels peaks in G1, prior to the onset of DNA replication. In situ immunofluorescence confirmed cell cycle regulation at the protein level. We propose a model in which H3K27me1 facilitates the assembly of ORC-dependent pre-replicative complexes (pre-RCs) during G1 phase. We speculate that the failure to establish pre-RCs triggers an alternative DNA replication program that bypasses the requirement for ORC. A recently published study, in which vegetative Orc1p levels are transiently reduced 50-fold, is consistent with the existence of an alternative pathway for the initiation of DNA replication in Tetrahymena.

C33 Beyond condensation: novel roles for condensin in the polyploid somatic nucleus of *Tetrahymena thermophila*. *R. Howard-Till*, J. Loidl. University of Vienna, MFPL, Chromosome Biology, Vienna, AT.

In most organisms, condensin proteins play an important role in organizing chromosomes for orderly segregation. This is also true in the ciliate *Tetrahymena thermophila*, where separate germline and somatic nuclei exhibit markedly different chromosomal organization and modes of division. The germline nucleus has 10 metacentric chromosomes that divide by mitosis and meiosis. The polyploid somatic nucleus divides by amitosis, a poorly understood process that results in random segregation of the chromosomes during a closed division. The *Tetrahymena* genome encodes one homolog each of the Smc2, Smc4, and CapG subunits of the condensin complex, two homologs of CapD, and four homologs of the kleisin (CapH/Barren). Smc2, Smc4, and CapG are shared between all the condensin complexes in the cell, but the CapD and kleisin subunits show nuclear specific localizations. As expected, condensin is required for condensation and segregation of germline chromosomes. However, previous work has also shown an unexpected requirement for condensin in the somatic nucleus. The somatic nucleus contains approximately 45 copies each of 181 chromosomes ranging in size from ~100 kb to ~2 mb. These chromosomes do not visibly condense prior to division, but condensin is clearly required for normal DNA segregation. Depletion of Smc2, CapD1 or Brn3 subunits results in aberrant divisions in which the nuclear membrane elongates and pinches off, but the chromatin is not distributed. Thus one daughter cell receives the majority of the DNA, while the other has very little. To better understand how condensin contributes to division, we have begun to investigate the organization of chromosomes in the somatic nucleus. FISH labeling of whole somatic chromosomes in wild-type cells shows distinct foci that are distributed fairly evenly throughout the nuclear space. In the absence of condensin, this distribution is disrupted, and the foci are clustered. Two color FISH of two different chromosomes shows that clusters do not overlap, indicating that chromatin is not just more dense in one part of the nucleus. These results indicate that condensin is involved in the organization of chromosomes in the somatic nucleus. Additional results indicate that a specialized condensin may also be involved in the generation of the somatic nucleus after sexual reproduction. Depletion of CapD2 during mating disrupts the process of somatic nuclear development, resulting in the retention of DNA elements that are normally eliminated. Nuclear development arrests without amplification to the normal DNA levels. Work is ongoing to determine the exact role of condensin in these processes, and promises to reveal novel roles for condensin in the generation and maintenance of an unusual polyploid nucleus.

C34 Repair of a fragile site in the mating type genes using an episomal template in *Tetrahymena*. *Marcella D. Cervantes*[1], Michael J. Lawson[2], Linying Zhang[1], Eileen Hamilton[3], Eduardo Orias[3], Geoffrey Kapler[1]. 1) Texas A&M Health Science Center, College Station, TX; 2) Uppsala University, Uppsala, Sweden; 3) University of California Santa Barbara, Santa Barbara, California.

The *Tetrahymena thermophila* somatic mating type genes offer an opportunity to understand an unusual mechanism for repairing fragile sites using episomal DNA as a template. *Tetrahymena* has seven possible mating types, and each is determined by the MTA and MTB gene pair. In the somatic nucleus, the gene pair is oriented head to head, sharing a presumed promoter region. Both genes are transcribed at a very low level during growth, but are induced to a high level of transcription by starvation. In the germline nucleus, the mating type locus contains an

array of truncated gene pairs. While the terminal exons of each gene are conserved between mating types, each copy of the conserved terminal exons contains polymorphic nucleotides unique to that particular copy. The germline array of genes is rearranged during somatic nuclear development by homologous recombination. PCR experiments suggests that recombination produces circular episomal byproducts that are retained in progeny for more than 120 fissions. Homologous recombination reduces the mating type locus to one complete gene pair in the new somatic nucleus. The pattern of polymorphic nucleotides shows up to 89% of the newly assembled MTB genes are produced by a single recombination event. Unexpectedly, older vegetative cells, do not exhibit a single recombination junction because the terminal exons have a mosaic of polymorphic nucleotides - presumably resulting from multiple gene conversion events. I propose that the template for these gene conversion events are episomal circular byproducts generated during mating type determination. I am addressing two questions regarding the episomes. The first question is whether the promoter region of the mating type gene pair can serve as an autonomously replicating sequence (ARS). To test the promoter region as an ARS, a plasmid with an *E.coli* backbone, a *Tetrahymena* selection cassette and regions of interest was transformed into vegetative *Tetrahymena*. We have obtained stable transformants that harbor a plasmid with the mating type VII promoter region. The second question is whether gene conversion within the conserved terminal exons occurs at a particular site due to replication fork pausing. Although the MTA and MTB genes acquire a mosaic of polymorphic nucleotides, they do not acquire mutations. This suggests homologous recombination. A pause site of DNA replication could explain the propensity for gene conversion in the terminal exons of MTA and MTB. The presence of pause sites in the terminal exons is being determined by 2D gel electrophoresis.

C35 Identification and Characterization of *Tetrahymena thermophila* Snf2/Swi2 ATPase Homologs involved in DNA Repair. *A. F. Morin*, J. J. Smith. Missouri State University, Springfield, MO.

The Snf2/Swi2 ATPase family of proteins is composed of different subfamilies with distinct functional roles, which can be classified based on the structure of their ATPase domains and other domains within the proteins. The Rad5/16 subfamily of Snf2/Swi2 ATPases is composed of Rad5 and Rad16, both of which play vital roles in different DNA repair pathways. Despite their activity in different repair pathways the structures of Rad5 and Rad16 are quite similar. Both contain the characteristic SNF2/SWI2 ATPase domains and, situated between the two ATPase domains, a Zinc-finger RING E3 ubiquitin ligase domain. Functionally, both Rad5 and Rad16 have ATPase activity, which is associated with chromatin remodeling to allow different proteins access to DNA, specifically at damaged sites. They also have E3 ubiquitin ligase activity, which is used to transfer ubiquitin molecules onto target substrates as a way of signaling for degradation or stability. The main difference between the two proteins is a characteristic HIRAN DNA binding domain, which is present at the N-terminus of Rad5, but absent in Rad16. Both proteins were initially discovered and characterized in *Saccharomyces cerevisiae*. Rad16 was demonstrated to be involved in nucleotide excision repair (NER), specifically global genome NER (ggNER). Rad5 was found to act in a variety of different instances, including: acting as a catalyst for translesion synthesis, acting in post replication repair as well as DNA double strand break (DSB) repair. Due to their roles, both proteins are extremely important as factors which help to enhance genome stability and promote ongoing genome integrity. *Saccharomyces* contains one constitutively silenced genomic locus, and since ggNER takes place in silenced areas of the genome this makes the study of ggNER proteins, such as Rad16, difficult. In contrast, *Tetrahymena thermophila* has a transcriptionally silent micronucleus, which provides a large platform for the study of Rad16 and ggNER. The goal of this work is to identify the homologs of both Rad16 and Rad5, while analyzing both their interactions and functions. Four putative homologs of Rad5/Rad16 were identified in *Tetrahymena* through bioinformatic analyses to elucidate sequence differences and similarities. Additionally, qRT-PCR analyses of homologs were conducted to determine expression in response to different DNA damaging agents; UV radiation to generate bulky adducts and induce NER, and methyl methanesulfonate (MMS) to induce DSB repair. To determine function in DNA repair and genomic integrity, shRNA constructs were created and transformed into cells to analyze the phenotypic consequences of decreased expression following UV and MMS damage.

C36 Interplay between the Homologs Rad51 and Dmc1 in Cell Division, Sexual Reproduction, and Homologous Recombination Repair. *Amaal Abulibdeh*[1], Allie Maltzman[1], Daniel Romero[2], Joshua Smith[1]. 1) Missouri State University , springfield, MO; 2) University of Minnesota, Minneapolis, MN.

Rad51 and Dmc1 promote the homologous and strand exchange steps of homologous recombination. The amino acid composition of both proteins is similar to that of RecA, containing a region of consensus sequence for nucleotide binding ss-and ds-DNA binding, and strand exchange. Dmc1 is a Recombinase involved in meiosis-specific repair of double strand breaks (DSBs) via homologous recombination, whereas Rad51 has been found to be involved in meiotic and non-meiotic DSBs repair. Microarray and RT-PCR data from previous studies in *Tetrahymena* have demonstrated that expression of DMC1 increases during meiosis and that the protein localizes to the micronucleus. Some studies in budding yeast show that when RAD51 is overexpressed, interhomolog recombination still occurs even when DMC1 is knocked out. . It is not known whether Dmc1 and Rad51 interact directly, but evidence suggests that they somehow work together. Rad51 and Dmc1 have not been fully characterized in the ciliate *Tetrahymena thermophila*. Previous studies demonstrated that without Rad51, DSBs were not repaired, but meiotic DSB repair is dramatically reduced in the absence of Dmc1 and the function of Dmc1 can be compensated by replacing with Rad51 promotor. The aim of this study is to further define the role of Rad51 verses Dmc1 in *Tetrahymena* and to determine if they interact with each other in a complex during the cell cycle and DNA repair. Overexpression of the RAD51 causes macronuclear division and chromosome copy number defects. Bioinformatics was used to compare Dmc1 and Rad51 homologues from various species. RT-PCR studies showed an increase in DMC1 mRNA expression after treatment with MMS, UV, and H2O2, suggesting a possible role for Dmc1in DNA repair outside of meiosis. Survivability studies show that knocking out DMC1 makes *Tetrahymena* more sensitive to MMS treatment, but not to UV or H2O2. Data suggests they may play both similar and distinct roles in meiotic recombination. The role of *Tetrahymena* Dmc1 in DNA repair will be further elucidated through immunoprecipitation, fluorescence microscopy, and overexpression studies.

C37 Both maternal and paternal scnRNAs can target excision of transposon-derived sequences during *Paramecium* development. *E. Meyer*, Guillaume Pellerin. IBENS, Paris, FR.

Like all ciliates, *Paramecium tetraurelia* entirely rearranges its genome during development of the somatic macronucleus from the germline micronucleus, in each sexual generation. Rearrangements include the precise excision of IESs (Internal Eliminated Sequences), single-copy intervening sequences likely derived from transposon insertions, from coding and non-coding regions of the genome. Correct genome rearrangements depend on a meiosis-specific class of small RNAs called scnRNAs. Initially produced from the entire maternal germline genome during meiosis, scnRNAs are thought to scan the maternal macronuclear genome which acts as a sponge to remove homologous molecules from the active pool, resulting in the selection of germline-specific scnRNAs that later allow the zygotic macronucleus to reproduce the same deletions. This genome scanning model raises a theoretical problem during conjugation between polymorphic strains : a heterozygous F1 cell should be unable to excise a scnRNA-dependent IES from the incoming (paternal) allele if that IES is absent from the maternal allele, or if its sequence is too divergent. Our results, however, indicate that divergent paternal alleles are correctly rearranged, using scnRNAs produced by the paternal cell. Germline-specific scnRNAs may be exchanged between conjugants along with gametic nuclei, or they may program IES excision at a very early stage, by targeting the deposition of unknown genomic imprints in gametic nuclei. I will present an update on experiments designed to test these hypotheses.

C38 Analysis of development-specific Piwi proteins in Paramecium. *D. Furrer*, E. Swart, M. Kraft, M. Nowacki. University of Bern, Bern, CH.

In ciliates, Piwi-bound small RNAs are involved in massive DNA elimination that takes place during sexual development. In Paramecium, we know so far of two classes of small RNAs involved in the excision of germline-limited DNA such as IESs and transposons. Scan RNAs (scnRNAs) are involved in the first round of the DNA elimination process. The later arising iesRNAs originate from eliminated IESs and are required to complete the DNA elimination.

We provide experimental evidence that Ptiwi01 and Ptiwi09 are essential for the scnRNA pathway and the elimination of maternally-controlled IESs. In addition we demonstrate that Ptiwi10 and Ptiwi11 are required for iesRNA-specific DNA elimination. Using deep sequencing we show that in both pathways the Ptiwi proteins select guide RNA strands from dsRNA Dicer cleavage products. Sequencing of DNA from different Ptiwi knock-downs also demonstrates that only one of the two small RNA pathways affects the excision of transposons.

Additionally we show that the late expressed Ptiwi10 and Ptiwi11, among many other proteins, are expressed from the new macronucleus and that their transcription depends on IES excision. We propose that the excision of IESs from proteins expressed in the new MAC may function as a checkpoint that maintains developmental timing.

In addition we are characterizing the remaining development-specific Ptiwi proteins to get a more detailed view of the complex role of small RNA-Ptiwi interactions in Paramecium development.

C39 Regulation of DNA elimination boundaries requires novel DNA-binding proteins that define heterochromatin domains. *Douglas Chalker*, Christine Carle, Vita Jaspan. Washington Univ in St. Louis, St. Louis, MO.

During development of the ciliated protozoan *Tetrahymena thermophila*, germline-derived DNA undergoes extensive reorganization including the removal of ~50Mbp in segments called internal eliminated sequences (IES's) from the differentiating somatic genome. The eliminated sequences are targeted for excision by small-RNA-directed heterochromatin formation. To ensure that the reorganized, gene-dense genome maintains all coding and regulatory sequences, the boundaries of the eliminated DNAs must be accurately defined. We have identified developmentally expressed proteins that define the boundaries of specific subsets of IESs. First, we discovered that the guanine-quadruplex binding protein, Lia3, specifically regulates the rearrangement of loci that are flanked by G-rich (5'-AAAAAGGGGG-3') boundary controlling sequences. Second, we characterized the Lia3-like protein 1 (Ltl1) and found that the IES's regulated by Ltl1, which include the D IES, are distinct from those regulated by the Lia3. Initial binding assays show that Ltl1 has a high affinity for double-stranded DNA, but does not bind single-stranded DNA. The IESs regulated by these two proteins comprise only a fraction of the thousands of eliminated loci. These results suggest that multiple proteins are required to accurately control the specification of heterochromatin domains that are targeted for removal from the somatic genome.

C40 Transiently maintained somatic chromosomes of *Tetrahymena* contain development-specific genes. *Y. Liu*[1], L. Feng[1], E. Hamilton[2], J. Xiong[3], G. Wang[3], W. Dui[1], L. Khadr[1], W. Miao[3], E. Orias[2]. 1) Department of Pathology, University of Michigan, Ann Arbor, MI 48109, USA; 2) Department of Molecular, Cellular, and Developmental Biology, University of California, Santa Barbara, CA 93106, USA; 3) Key Laboratory of Aquatic Biodiversity and Conservation, Institute of Hydrobiology, Chinese Academy of Sciences, Wuhan 430072, China.

In the ciliate *Tetrahymena*, programmed genome rearrangement events accompany the differentiation of the somatic macronucleus (MAC) from the germline micronucleus (MIC). Internal eliminated sequences (IES), most of which are likely derived from transposable elements, are excised by an RNAi-dependent pathway. Furthermore, the 5 MIC chromosomes are fragmented into ~200 MAC chromosomes at highly conserved chromosome breakage sequences (CBS), followed by *de novo* telomere addition. Intriguingly, some MAC chromosomes are lost soon after MAC differentiation, thereafter referred to as non-maintained macronuclear chromosomes (NMC).

Systematic comparison between the MIC and MAC genome sequences reveals several large NMC. In contrast to IES, NMC are still present in developing MAC during late conjugation. More importantly, these NMC generate high levels of mRNA, but very low levels of small RNA. Many NMC-contained genes encode conserved proteins, potentially involved in development-specific events. Here we focus on NMC-3 (~12 kb), which contains TPB3, a putative PiggyBac transposase with potential roles in IES excision. NMC-3 is quickly lost in mature MAC during asexual propagation, attributable to lack of efficient replication origins. Deleting either the left or right flanking CBS effectively prevents its loss. TPB3 is

expressed late in conjugation, during developing MAC formation of the progeny. Deleting NMC-3 from the germline MIC of parental cells—and consequently developing MAC of the progeny—abolishes TPB3 expression. Conjugation progress delay and progeny growth defects are also observed. Sequencing developing and mature MAC genomes from these progeny reveals that a small subset of IES is affected. We conclude that these NMC contain development-related genes, providing a novel mechanism for achieving a highly specific gene expression pattern.

C41 Cell cycle control of histone methyltransferase TXR1 levels is required for proper DNA replication in *Tetrahymena*. *Shan Gao*[1], Yifan Liu[2], Geoffrey Kapler[3], Jie Huang[1], Xiaolu Zhao[1,2], Xiao Chen[1]. 1) Institute of Evolution & Marine Biodiversity, Ocean University of China, Qingdao 266003, China; 2) Department of Pathology, University of Michigan, Ann Arbor 48109, USA; 3) Department of Molecular and Cellular Medicine, College of Medicine, Texas A&M Health Science Center, College Station, TX 77843, USA.

DNA replication is tightly controlled by histone-modifying enzymes. In the ciliate *Tetrahymena,* knockout of histone methyltransferase TXR1 (TXR1 KO), specific for H3 lysine 27 mono-methylation (H3K27me1), leads to severe replication stress and DNA damage response. Here we investigate the mechanism by which DNA replication is regulated by TXR1. We demonstrate a cell cycle-dependent oscillation of TXR1 at mRNA and—more strikingly—protein levels. TXR1 peaks in G1 phase but is quickly depleted upon entering S phase. Correspondingly, H3K27me1 is built up slowly in newly synthesized histones, showing a much higher level in G1 phase than G2 phase. TXR1 degradation in S phase is most likely mediated by PCNA, as point mutations at the PCNA-interacting protein (PIP) motif cause TXR1 to accumulate at S phase. Strains with TXR1 PIP mutations as well as TXR1 overexpression show replication defects, which are distinct from the TXR1 KO phenotype. We therefore conclude that cell cycle control of TXR1 levels ensures proper DNA replication in *Tetrahymena*.

C42 Functional analysis of the Ibd1 protein in *Terahymena thermophila*. *A. Saettone*[1], A. Burtch[1], J. Garg[2], J. Lambert[3], A. Gingras[3], R. Pearlman[2], J. Fillingham[1]. 1) Department of Chemistry and Biology, Ryerson University, Toronto, Ontario, Canada; 2) Department of Biology, York University, Toronto, Ontario, Canada; 3) Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, Ontario, Canada.

The objective of this research is to identify and initiate functional characterization of the SWI/SNF complex in the unique chromatin environment of *Tetrahymena thermophila*. Through affinity purification followed by mass spectrometry (AP-MS), we identified the first SWI/SNF complex in protists through the reciprocal interaction of Snf5 and a small bromodomain containing protein (Ibd1). Through AP-MS of Ibd1 I found Ibd1 is versatile and interacts with several additional putative chromatin remodeling complexes such as a HMT, and SAGA and SWR. Bromodomains have affinity for acetylated lysine residues. Our peptide array experiment suggests that Ibd1 has affinity to multiple acetylated PTM related to highly transcribed regions. We found that indirect immunofluorescence (IF) of Ibd1 hints at a role in transcription. We are developing a protocol to use ChIP-Seq to identify the Ibd1 binding sites in the genome during growth.

C43 GCN5, ESA1, and CHD1: More Than Just Transcription Regulators? *J. J. Smith*, L. A. Andreas. Missouri State University, Springfield, MO.

The packaging of chromatin plays a vital role in the ability of the genes to be accessible or inaccessible to transcription which leads to expression or prevention of protein formation. Acetylation decreases the DNA-histone interaction allowing the chromatin to become euchromatin or transcriptionally active DNA. GCN5, ESA1, and CHD1 are three proteins that are involved in this process. GCN5 and ESA1 are histone acetyltransferases (HATs) and CHD1 is a bromodomain containing protein that is recruited to sites of acetylation. Tetrahymena thermophila are the ideal organism to study chromatin packaging because they contain a macronucleus and micronucleus that separate acetylation and transcription. It has been shown that chromatin modification can also allow access for DNA repair mechanisms. This research specifically focuses on GCN5, CHD1, and ESA1's function in Tetrahymena in chromatin regulation and DNA repair. The characterization of these proteins in Tetrahymena will allow for a better understanding of their exact role in DNA repair and genome stability. An interesting phenotype of GCN5 overexpression has been observed when cells are under starved conditions and was also studied in this research.

C44 MAC-specific Chromatin Remodelers bind a Zinc Finger Protein and Diverse RNAs throughout the *Tetrahymena* Life Cycle. *E. F. DeRango-Adem*[1], J. Garg[1], C. Mudalige[2], A. Saettone[2], J. P. Lambert[3], A. C. Gingras[3], J. Fillingham[2], R. Pearlman[1]. 1) York Univ., Toronto, Canada; 2) Ryerson Univ., Toronto, Canada; 3) Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, Canada.

In a screen for ATP-dependent chromatin remodeling proteins in *Tetrahymena thermophila*, we identified and partially characterized two conserved Chromodomain Helicase DNA-binding (Chd) proteins of the SNF2 superfamily, Chd3 and Chd7. *Tetrahymena* Chd proteins have essential and diverse functions in growth and development. These proteins contain chromo-, bromo-, and PHD- domains and classically bind DNA. Chromodomain proteins and other ATP-dependent chromatin remodelers can also bind mRNAs, as well as ncRNAs during transcriptional silencing. These nucleic acid binding complexes are called DNA- and RNA-binding Proteins (DRBPs). DRBPs likely play a role in promoting recognition and removal of Internal Eliminated Sequences (IES) and irreversible genome silencing. A bioinformatic analysis of developmental-specific *Tetrahymena* proteins with DNA *and* RNA binding domains identified Chd3 and Chd7 among candidate DRBPs. To study three-way DNA:RNA:protein interaction, a three-way immunoprecipitation protocol was used. **P**rotein **I**mmuno**p**recipitation (PIP), **Ch**romatin **I**mmuno**p**recipitation (ChIP), and **R**NA **I**mmuno**p**recipitation (RIP) were used to identify DRBP interactions in an experimental setup called IP3.

FZZ-tagged constructs of Chd3 and Chd7 were transformed into *Tetrahymena* for expression analysis, localization, and purification. Indirect immunofluoresence in vegetative growth localized these proteins to the macronucleus (MAC). During development, Chd3 and Chd7 expression was lost in the old MAC, and localized exclusively in the developing MAC from 6-8 hours of conjugation. There was no localization to micronuclei (MIC) at any time. This is indicative of zygotic expression in anlagen, consistent with microarray and RNA-seq expression data. Affinity purification/mass spectrometry (APMS) of Chd3 and Chd7 in vegetative and conjugating cells indicate interaction with core histone proteins, heat shock protein 70, and an RNA-recognition motif protein. We have focused on and will discuss the interaction of a previously

uncharacterized MIZ Ring zinc finger (Znf) protein with Chd3. RNA immunoprecipitation and Urea-PAGE show Chd3 and Chd7 bind diverse RNAs, including multiple long RNAs, a 100nt ssRNA and an 80nt ssRNA species. Experiments in progress to be presented include RNAseq to identify RNA species immunoprecipitated, ChIP analysis to identify loci the DNA-binding chromatin remodelers are recruited to, and protein microarray analysis to identify histone modifications bound by Chd proteins.

C45 Homology dependent heterochromatin formation by *trans* acting RNAi in *Paramecium tetraurelia*. *M. Simon*[1], M. Cheaib[1], U. Götz[1], S. Marker[1], R. deWijn[1], A. Rodrigues[1], D. Durai[2], V. Oruganti[2], K. Nordström[2], S. Karunanithi[1,2], M. Schulz[2]. 1) Molecular Cell Dynamics Saarland University, Centre for Human and Molecular Biology, Campus A2 4, 66123 Saarbrücken, Germany; 2) Cluster of Excellence, Multimodal Computing and Interaction and Max Planck Institute for Informatics Saarland University, Department for Computational Biology and Applied Algorithmics, Campus E1 4, 66123, Saarbrücken, Germany; 3) Department for Genetics, Saarland University, Centre for Human and Molecular Biology, Campus A2 4, 66123 Saarbrücken, Germany.

Across kingdoms, RNA interference (RNAi) has been shown to control gene expression at the transcriptional- or the post-transcriptional level. Here, we describe mechanisms in which different classes of siRNAs trigger heterochromatin formation *in trans*. First, injection of truncated transgenes, unable to produce translatable mRNA, produce predominantly antisense siRNAs which depend on a variety of RNAi components. These include RDR3, HEN1 & PTIWI14 as well as a second set of components, which are also involved in post-transcriptional silencing: RDR2, PTIWI13, DCR1 and CID2. Our data indicates differential processing of nascent un-spliced and long, spliced transcripts. As transgene derived siRNAs trigger repressive histone marks at the remote loci, this suggests a functional interaction between post-transcriptional and co-transcriptional RNAi: next to a loss of H3K9ac and H3K4me3, increased levels of histone occupancy and H3K27me3 can be observed. This is accompanied by secondary siRNA accumulation, strictly limited to the open reading frame of the remote locus. Next to this exogenously triggered RNAi, also the endogenously controlled mutual exclusive expression of the surface antigen family depends on RDR3, HEN1, DCR1 and DCL4. Here, silent genes show surprisingly high levels of H3K4me3 and they exhibit very low levels of 23nt antisense RNAs. Surprisingly, actively transcribed antigen genes produce high levels of 23nt sense siRNA produced from the entire length of the mRNA. As silencing of RDR3 disrupts mutual exclusive expression as all surface antigens are co-expressed, this is accompanied with loss of sense siRNAs and accumulation of antisense siRNAs of the entire coding genome. As the data suggests that RDR3 and RDR2 compete for different classes of precursor RNAs, we classified siRNA clusters of the entire genome by their dependency on different RNAi components and compared these with chromatin data. This indicates that similar mechanisms to transgene induced silencing and serotype regulation contribute to transcriptome regulation by post-transcriptional and transcriptional silencing.

C46 The Enhancer of zeste like protein Ezl1 is required for scnRNA selection and transcriptional repression of transposon-derived sequences in *Paramecium tetraurelia*. *Andrea Frapporti*[1], Olivier Arnaiz[2], Maoussi Lhuillier-Akakpo[1], Augustin de Vanssay[1], Caridad Miro Pina[1], Raphaël Margueron[3], Sandra Duharcourt[1]. 1) Institut Jacques Monod, CNRS, UMR 7592, Sorbonne Paris Cité, Paris, France; 2) Institute of Integrative Biology of the Cell, UMR9198 CNRS CEA U Paris-Sud,91198 Gif-sur-Yvette, France; 3) Institut Curie, Paris Sciences et Lettres Research University, INSERM, U934, CNRS, UMR3215, Paris, France.

In the unicellular eukaryote *Paramecium tetraurelia,* differentiation of the somatic macronucleus (MAC) from the zygotic nucleus is characterized by massive and reproducible rearrangements of germline DNA, that include the elimination of transposable elements and 45,000 short, single-copy internal eliminated sequences (IESs). A specific class of small RNAs, the scnRNAs that are produced by the germline micronucleus (MIC) through a meiosis-specific RNAi pathway, is essential for DNA elimination of homologous sequences in the developing MAC. The mechanisms that allow specific recognition of germline-limited sequences within chromatin remain an open question. We identified recently a *Paramecium* homolog of mammalian Enhancer-of-zeste, Ezl1 that is required for the establishment of both H3K27me3 and H3K9me3 epigenetic modifications during development and for programmed genome rearrangements (Lhuillier-Akakpo, 2014). Here, we show that the Ezl1 protein is a *bona-fide* histone methyl-transferase, whose catalytic activity is necessary *in vivo* for histone H3 trimethylation on lysines 27 and 9 and for correct elimination of germline-limited DNA. We used RNA sequencing to measure steady state RNA levels from *EZL1* knockdown (KD) cells at different time points during development. Analysis of small RNA datasets revealed that scnRNA biogenesis is not affected upon Ezl1 depletion as compared to control. Yet elimination of MAC-specific scnRNAs from the initial pool of scnRNAs, a process that normally leads to MIC-specific scnRNA enrichment during development, is abrogated in *EZL1* KD. Ezl1 depletion also caused a sharp rise in transposon-derived transcripts. Altogether our data suggest that the histone methyltransferase Ezl1 is required for MIC-specific scnRNA selection and for transcriptional repression of transposon-derived sequences.

C47 Proteomic Characterization of *Tetrahymena thermophila* Chromatin Assembly Proteins. *J. Garg*[1], S. Nabeel-Shah[2], J.-P. Lambert[3], A.-C. Gingras[3,4], R. P. Pearlman[1], J. Fillingham[2]. 1) York University, Toronto, Ontario, CA; 2) Department of Chemistry and Biology, Ryerson University, Toronto, Ontario, Canada; 3) Samuel Lunenfeld Research Institute, Mount Sinai Hospital, 600 University Avenue, Toronto M5G 1X5, Canada; 4) Department of Molecular Genetics, University of Toronto, Toronto M5S 1A8, Canada.

In humans, transport of histones H3/H4 from the cytoplasm to the nucleus occurs in a stepwise fashion and is mediated by protein factors including HSP90, NASP, Asf1 and Importin4. Cells can adopt two different pathways to assemble chromatin, namely replication dependent and replication independent pathways which are mediated respectively by “Chromatin Assembly Factor 1 (CAF1)” and “Histone Regulator A (HIRA)” protein complexes. Despite their identification, the mechanistic details of H3/H4 transport and subsequent deposition onto DNA remains unclear. To address this, we have performed proteomic characterization of Asf1, NASP, CAF1 and Hat1 in *Tetrahymena* using affinity purification combined with mass spectrometry approach. *Tetrahymena* is an excellent model system to study chromatin related processes

providing that it features nuclear dualism in the form of a transcriptionally active macronucleus and a silent micronucleus. Our results indicate that NASP physically interacts with Asf1 and HSP90 and thus likely functions in H3/H4 transport suggesting an evolutionarily conserved nature of this pathway. We also show that the three protein CAF1 complex (Cac1, Cac2, Cac3) interacts with H3/H4 as well as with Casein Kinase 2 (CK2), an evolutionary conserved SER/THR protein kinase. Our MS data also indicates that Hat1 co-purifies with H4 and a putative Hat2 protein. Interestingly, we found that Hat2 subunit of HAT complex is also shared by CAF1 complex as its Cac3 subunit. We have named this protein SSCH1 (Shared Subunit of CAF-1 and Hat1). This suggest that SSCH1 exists in two separate pools of protein complexes and is capable of carrying functions that are divided between two separate proteins in higher eukaryotes such as humans.

C48 Signaling and Cell Cycle Studies in *Tetrahymena thermophila*. *R. E. Pearlman*[1], W. Ahmad[1], J. Garg[1], A. Kume[1], M. Anafi[1], W. Glowacka[1], J.-P. Lambert[2], A.-C. Gingras[2], J. Fillingham[3]. 1) York University, Toronto, Ontario, CA; 2) Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, Ontario, CA; 3) Ryerson University, Toronto, Ontario, CA.

Phosphotyrosine signaling in response to growth factors and its involvement in cell cycle regulation is widely believed to be a key signal in vertebrate and invertebrate cells to determine their fate. In multicellular organisms, protein tyrosine phosphorylation is well known to have a pivotal role in the coordination of signal transduction in response to extracellular stimuli involved in the control of a wide range of cellular processes. Until recently, tyrosine phosphorylation signaling was thought to be limited to multicellular organisms and most of the studies in this field are therefore with multicellular organisms. Some recent publications however suggest a role for tyrosine phosphorylation in signaling in unicellular eukaryotic organisms as well. Recent work in our laboratory with *Tetrahymena thermophila* has provided both experimental and bioinformatic computational evidence for tyrosine phosphorylation. The dynamics of tyrosine phosphorylation in *T. thermophila* in a mating type specific manner and the role such phosphorylation might play in this unicellular eukaryote have been examined. Key questions addressed in this work are to identify the pathway(s) of tyrosine phosphorylation in *Tetrahymena* including proteins associated with pathway components already identified and to identify sites of tyrosine phosphorylation on proteins that we have suggested to be involved in tyrosine phosphorylation in *Tetrahymena*.

Genes of interest were obtained using PCR and the available *Tetrahymena* complete genome sequence (www.ciliate.org) and 3' tagged with FZZ. Constructs in this study include 4 protein tyrosine kinases and two protein tyrosine phosphatases. Plasmid DNAs were introduced into *Tetrahymena* by biolistic transformation and gene replacements were made homozygous using phenotypic assortment. Western blot and indirect immunofluorescence (IF) were used to confirm expression and localization of the tagged proteins. Affinity purification/mass spectrometry (AP/MS) to identify protein/protein interactions has been carried out and will be described. Bioinformatic including gene network analysis is used in combination with biological approaches such as gene knock out and gene knock down to describe the network of interacting proteins to gain additional insight into biological function.

C49 A potential role for TtSNX4 in macronuclear degradation in *Tetrahymena thermophila* Conjugation. *S. Guerrier*[1], A. Ariatti[1], B. McField[1], M. Cervanted[2], G. Kapler[2]. 1) Millsaps College, Jackson, MS; 2) Texas A and M Health Science Center, College Station, TX.

Organellophagy is the selective degradation of organelles by autophagosomes. Alterations in organellophagy are associated with several disorders including neurodegeneration, heart disease, obesity, and cancer. Selectivity in organellophagy is achieved by the specific binding autophagosome protein ATG8 to proteins on the target compartment. A distinct set of proteins is then used by selective autophagy pathways to expand the autophagosome around the specific target. Nucleophagy, the selective degradation of the nucleus by autophagosomes, is up regulated in laminopathies and in response to oncogenic stress. But whether nucleophagy utilizes proteins that are required for selective autophagy patways remains unclear. Our primary goal is to understand the molecular mechanisms underlying how the nucleus is specifically degraded by autophagosomes. In order to uncover these mechanisms we plan to exploit nuclear degradation during mating in *Tetrahymena thermophila*. *Tetrahymena* selective degrade their entire (macronucleus) nucleus in an autophagy dependent manner, as part of normal mating. Importantly this process can be induced in the lab and occurs in predictable and identifiable stages making nucleophagy in *Tetrahymena* straightforward to monitor. Preliminary work in our lab has shown that nucleophagy in *Tetrahymena*, may employ selective autophagy proteins. Specifically, we identified a *Tetrahymena* homolog of SNX4 (TtSNX4), a protein that is required for the selective degradation of mitochondria by autophagosomes (mitophagy) in yeast as candidate for regulating nucleophagy in *Tetrahymena*. We find that TtSNX4 localizes specifically to the degrading nucleus in a phosphoiositide 3 kinase (PI3K) dependent manner and deletion of TtSNX4 results in impaired nuclear condensation, an early stage in the degradation process that is dependent on nucleases provided by mitochondria that have been engulfed by autophagosomes. Importantly, proteins like SNX4, that possess PX-BAR domains have been shown to bind PI(3)P, a peoduct of PI3K. Therefore we hypothesize that TtSNX4 may regulate the delivery of mitochondrial nucleases to the nucleus in a PI(3)P dependent manner.

C50 Characterization of the ubiquitin-like modifier *Urm1* in the Ciliate *Tetrahymena thermophila*. *J. Copeland*, J. Smith. Missouri State University, Springfield, MO.

Ubiquitin-Related Modifier (Urm1) is a small protein with the characteristic ubiquitin Beta-grasp fold and Carboxyl termini diglycine motif. It has been implicated in two cellular functions: conjugation to substrate proteins during oxidative stress, such as pAhp1 and in the thiolation of wobble uridines in certain cytosolic tRNAs. Both processes require activation by E1-like enzyme Uba4, which has a C-terminal rhodonase domain and demonstrates both sulfurtransferase and acetyltransferase activity. Once Urm1 is activated by Uba4, the other members of the Urm1 tRNA-thiolation pathway: Ncs6, Ncs2, Tum1, Nsf1 will help mediate the transfer of the sulfur onto the uridine. Urm1 Thiolation of tRNAs is ubiquitous to life and highly conserved. It has been linked to various cellular stress responses: heat shock, misfolded protein response and

oxidative stress as well as several signal transduction pathways: notably mTOR and JNK. However, it's been shown several times that Urm1 knockouts have minimal phenotypic consequences. Urm1 is particularly interesting because it believed to be the most ancient Ubiquitin-like Protein (Ubl), and appears to be an evolutionary link between Eukaryotic Ubiquitination and Molydopterin Cofactor (MoCo) synthesis, which is present in Prokarea and most of Eukarya. This is supported by evidence that the Uba4 homolog in Arabidopsis thaliana is responsible for activating both Urm1 and MoCo Synthesis Pathways. Urm1 was first characterized in Saccharomyces cerevisiae, but there is a need to demonstrate tRNA thiolation activity of homologs in other organisms. This work will characterize Urm1 in Tetrahymena thermophila, a model organism useful for its quick growth as well as its relatively easy genetic engineering through homologous recombination. There will be bioinformatics data focusing on protein structure and function, as well as sequence homology to support the role of Urm1 in ubiquitin evolution. Expression profiles of Urm1 will be performed using qRT-PCR of T. thermophila grown in different growth conditions, focusing particularly on oxidative stress and heat shock. Fluorescence microscopy co-localization studies will be performed for Urm1 and the other pathway members, using genes that have been endogenously tagged with fluorophores.

C51 Early stages of diversification in the Rab GTPase gene family revealed by genomic and functional studies in *Paramecium* species. *L. Bright*, J.-F. Gout, M. Lynch. Indiana University, Bloomington , IN.

New gene functions arise within existing gene families as a result of gene duplication and subsequent diversification. However, the evolutionary forces that act on gene duplicates (paralogs) over time, as well as the intermediate steps on the path to functional change, are not well understood. In an effort to understand functional diversification in paralogs on both the genomic and subcellular level, we tracked duplicate retention patterns and subcellular markers of functional diversification in the Rab GTPase gene family in *Paramecium aurelia* species. Rab GTPases are on the whole more highly expressed and more highly retained than other genes in *Paramecium* genomes after whole genome duplication (WGD). Additionally, consistent with early steps in functional diversification, expression levels of these recent Rab paralogs appear to be diverging more rapidly from one another than other genes in the genome. We uncovered evidence of diversification at the subcellular level by localizing GFP-tagged paralogs from the Rab11 subfamily. Because the functionally diversifying paralogs are closely related to and derived from a clade of functionally conserved paralogs, we were able to pinpoint two specific amino acid residues that may be the drivers of the change in localization and, thus, function. Interestingly, the functionally conserved proteins label compartments involved in both endocytic recycling, the conserved Rab11 function, and phagocytic recycling, revealing evolutionary links between the two pathways.

C52 The detection of intracellular cAMP fluctuations – a sensitive *in vivo* assay to investigate signal transduction pathways in *Tetrahymena thermophila*. *D. P. Romero*. University of Minnesota, Minneapolis, MN.

Cyclic adenosine 3',5'-monophosphate (cAMP) is an important 2nd messenger involved in signal transduction pathways in diverse organisms from bacteria to mammals. Extracellular stimuli, including variable ionic conditions and drugs, can modulate cytoplasmic adenylyl cyclase activity via their effect on transmembrane proteins such as ion channels and G-protein coupled receptors. Through its influence on downstream signaling pathways, cAMP modulates various biological processes including metabolism, differentiation, cell adhesion and neuronal signaling. Standard methods to determine intracellular cAMP levels include radioimmunoassay (RIA) and competitive enzyme-linked immunosorbant assay (ELISA). Although quite sensitive, these immunological methods are time consuming and entail cell lysis and extensive processing steps. In an effort to streamline the detection of intracellular cAMP in *Tetrahymena thermophila,* and to make it possible to measure fluctuations of cAMP *in vivo* and in real time, the GloSensor™ cAMP Assay (www.promega.com), designed for transient expression in mammalian cells, has been adapted for use in *Tetrahymena.* The assay is based on a chimeric protein that includes a cAMP binding domain fused to mutant forms of *Photinus pyralis* luciferase. Upon binding intracellular cAMP, conformational changes alter the chimeric reporter tertiary structure, resulting in a reconstituted luciferase activity and a large increase in light output in the presence of the GloSensor™ substrate. *Tetrahymena t.* strains expressing the GloSensor™ reporter from the constitutive *BTU1* transcriptional promoter have been constructed. The stable transformant strains are able to take up the GloSensor™ substrate readily. Using 96-well plates (approx. 40,000 cell/well) and a plate reader with luminometer capabilities, cAMP levels can be measured to gauge the effect of various chemical compounds and growth conditions in a live-cell, non-lytic assay format. It is possible to monitor changes in cAMP levels in cells responding to stimuli in real time. This system will make it possible to screen complex compound libraries for ligands that affect G-protein coupled receptor (GPCR) function in *Tetrahymena.* An initial screen of the Pathogen Box (http://www.pathogenbox.org), composed of 400 diverse, drug-like molecules active against neglected diseases of interest, is currently ongoing.

C53 Polycystin-2 (Pkd2) and its unexpected role in Mg^{2+} permeability in *Paramecium*. *M. S. Valentine*, J. Yano, J. L. Van Houten. University of Vermont, Burlington, VT.

The non-selective cation channel polycystin-2 (Pkd2) is a member of the transient receptor potential (TRP) family of proteins and when mutated, can lead to autosomal dominant polycystic kidney disease. Here, we use the ciliated cell *Paramecium tetraurelia*, to examine Pkd2 in both the cilia and the cell membrane, together or separately, using deciliated or intact cells. *Paramecium* has two paralogs for Pkd2: *PKD2a* and *PKD2b*, which are 85% identical at the nucleotide level. Depletion of the mRNA for these paralogs using RNA interference (RNAi) results in reduced backward swimming, specifically in Mg^{2+} solutions, and a resistance to heavy metal toxicity. Our results suggested Pkd2 may play a role in the Ca^{2+}-dependent Mg^{2+} pathway because the results are similar to the phenotype of *eccentric* (XntA1), a mutant that is defective in Mg^{2+} conductance. We localized the Pkd2 and XntA proteins by expressing the genes using a plasmid containing a 3' terminal 3×FLAG or 3×myc sequence. The Pkd2-FLAG and XntA-FLAG (or XntA-myc) proteins localize in the cell membrane and in the cilia, as confirmed by immunoprecipitation (IP), immunofluorescence, and Western blot. Using FLAG and myc affinity agarose, we IP'd the epitope-tagged versions

of the proteins and demonstrated that XntA-myc co-IPs Pkd2-FLAG, but not *vice versa*. These data suggest a potential C-terminal interaction of the Pkd2-FLAG protein with XntA-myc, where the FLAG epitope is probably masked by the Pkd2 protein. To tease apart the contributions of the Pkd2 channel at the cell membrane and in the cilia, we utilized electrophysiology and membrane potential measurements to assess the permeability of *Paramecium's* membrane to Mg^{2+}. Our data suggest that Pkd2 is both necessary and sufficient for Mg^{2+} permeability of the cell membrane and that Pkd2 in the cilia may require the XntA protein; that without XntA, Pkd2 cannot function in the cilia. We propose that the Pkd2 channel is responsible for membrane permeability to Mg^{2+} while the role of the XntA protein, which is still under investigation, appears to be important for channel positioning or communication among channels in the membrane.

This project was supported in part by NIH Grant Numbers GM59988 and 5 P30 RR032135 and NIGMS grant 8 P30 GM103498. DNA sequencing performed in the VT Cancer Center supported in part by IDeA from NIGMS of NIH under grant P20GM103449.

C54 Whole genome sequencing of a Tetrahymena mutant reveals that VPS8, a subunit of the CORVET complex, is essential for biogenesis of mucocysts. *D. Sparvoli*[1], C. Kontur[2], X. Lan[3,4], J. K. Pritchard[3,4], A. P. Turkewitz[1]. 1) The University of Chicago, Chicago, IL; 2) Yale University, New Haven, CT; 3) Stanford University, Stanford, CA; 4) Howard Hughes Medical Institute, Stanford, CA.

In the ciliate *Tetrahymena thermophila*, regulated secretion of peptides occurs from dense core granules named mucocysts. Prior work from our laboratory revealed that mucocyst biogenesis depends on several proteins associated with lysosomes and lysosome-related organelles, namely cathepsins and VPS10/sortilins. To identify additional factors required in this pathway, we have used whole genome sequencing to analyze a recessive Mendelian mutant, called UC616, that is defective in mucocyst biogenesis. In an F2 mutant pool derived by outcrossing and then backcrossing UC616, we identified a homozygous single nucleotide variant predicted to alter a splice junction within a *Tetrahymena* homolog of the *VPS8* gene, which we call TtVPS8a. The mutation in TtVPS8a indeed inhibits intron excision and introduces a premature stop codon in the N-terminal domain of the protein. Importantly, the mucocyst biogenesis defect in UC616 can be fully rescued by endogenous-level expression of a full length, GFP-tagged copy of TtVPS8a. Yeast VPS8 encodes a subunit of CORVET, a complex shown to mediate vesicle tethering in the endolysosomal system in yeast and mammals. In UC616, mucocysts are absent and a protein that forms the wildtype mucocyst core instead accumulates in heterogeneous cytoplasmic compartments. Interestingly, *T. thermophila* and related ciliates have multiple paralogs of VPS8 and other CORVET-complex subunits, while lacking subunits that are specific to the related HOPS complex in fungi and animals. *Tetrahymena* maintains several distinct organelles, in addition to mucocysts, which appear related to lysosomes, and our results suggest that specialized paralogous CORVET tethering complexes may play an important role in their biogenesis. Our results also highlight the accessibility of this organism to forward genetic approaches, to interrogate this and other pathways.

C55 Using Chlamydomonas to understand cilia assembly. *S. K. Dutcher*, Huawen Lin, Suyang Guo, Robyn Roth. Washington Univ Sch Med, St Louis, MO.

The eukaryotic cilium is a complex machine with over 600 polypeptides. Motile cilia move cells or fluids. Motile and primary cilia play roles in signaling. Cilia both send and receive signals from the environment. Defects in these organelles cause a wide range of human diseases that include cancer, obesity, retinal degeneration, kidney and bone diseases as well as neurocognitive defects. We use *Chlamydomonas reinhardtii*, to understand the assembly and function of cilia. Ciliary proteins are highly conserved throughout the eukaryotic lineage and model organisms have been key in identifying and understanding human ciliopathies. We have been addressing three key questions using electron tomographic, biochemical, and genetic approaches. First, how are the large protein assemblies of motile cilia assembled in the cytoplasm? Second, how are cytoplasmic proteins kept out of cilium? Third, how are membrane vesicles used for ciliary signaling? Primary ciliary dyskinesia (PCD) is a disease in which the motility of cilia on the multi-ciliated epithelia of the respiratory tract is compromised. We are examining the roles of several proteins (HEATR2, DYX1C1, and IDA3) in the cytoplasmic assembly of the dynein arms. Proteins that localize to the transition zone, which spans from the triplet microtubules of the basal body, a modified centriole, to the doublet microtubules of the ciliary axoneme cause a variety of ciliopathies characterized by kidney defects, polydactyly, and retinal degeneration. We have found that some of these transition zone proteins (NPHP4, CEP290, RPGRIP1L) as well as proteins needed for intraflagellar transport (IFT172, IFT144, IFT52) are needed for the assembly of highly organized arrays of transmembrane proteins in the ciliary necklace, which is in the ciliary membrane surrounding the transition zone. It has been postulated that the transition zone and/or the ciliary necklace provide the barrier to the entry of cytoplasmic proteins into cilia. Using mass spectroscopy of isolated flagella, we find that that the ciliary necklace does not provide barrier function. The absence of transition zone proteins affects the barrier. Loss of RPGRIP1L has the strongest effect on the barrier; the 26S proteasome and the TRiC/CCT chaperonin complex enter the mutant cilia. Understanding the consequences of the entry of these proteins is underway. Studies in *Chlamydomonas* and *C. elegans* showed that membrane vesicles referred to as ectosomes are released from the ciliary membrane (Wang et al., 2015; Wood et al., 2013; Cai et al., 2015). These ectosomes carry signaling activity. We have found that the transition zone protein, RPGRIP1L, plays a role in the production of signal-containing ectosomes. The identification of new mutants is being pursued to understand the role of the transition zone in ectosome production and signaling.

C56 Role of molecular motors and microtubule-binding proteins in cell polarity and regeneration of Stentor. *T. Makushok*, W. Marshall. UCSF, San Francisco, CA.

Cells rely heavily on their polarity establishment and maintenance mechanisms, because proper polarization is required for performing a wide range of cell functions. The unicellular ciliate Stentor is an excellent model system for studying polarity due to its giant size, extraordinary level of structural regularity of its cytoskeleton, and amenability to microsurgical manipulation. Importantly, Stentor has the capacity to regenerate any of its parts, which gives access to studying the re-establishment of polarity perturbed in a wide variety of ways. In this study, we used RNAi

to analyze the role of Stentor cytoskeleton and molecular motors in cell motility, cell polarity, dynamic cell shape control, and regeneration. We show that cytoplasmic dyneins are essential for cell polarity maintenance, with abnormal cell morphologies observed when the corresponding genes are knocked down. We also observed that when kinesin gene is knocked down, Stentor cells are unable to extend to their full length. This suggests that kinesin may be involved in the sliding of microtubule sheets within microtubule rows running parallel to the main axis of the cell. Sliding within this complex cytoskeletal structure is thought to provide the mechanistic basis for Stentor dynamic shape changes. In addition to cytoplasmic dyneins and kinesin, we uncovered B subunit of the protein phosphatase PP2A as a major player in Stentor morphology control. Thus, our results provide insights into the molecular basis of Stentor morphology maintenance and dynamic cell shape control. Better molecular understanding of Stentor amazing ability to regenerate is essential, because it may lead to advancements in regenerative medicine.

C57 Kinome analysis in the giant ciliate *Stentor coeruleus*. *S. B. Reiff*, P. Sood, J. G. Ruby, M. Slabodnick, J. DeRisi, W. Marshall. Univ of CA, San Francisco, San Francisco, CA.

The giant unicellular ciliate *Stentor coeruleus* has the ability to fully regenerate after being cut in half, in a way that perfectly preserves cell polarity and structure. This regenerative ability has made it a classical model system for studying regeneration at the cellular level. So far, however, the molecular details behind this incredible phenomenon have remained largely unstudied. Recently, our laboratory has developed a system for RNAi knockdown of Stentor genes, and additionally sequenced the *Stentor coeruleus* genome. Interestingly, not only do Stentor's introns appear to possess the smallest average intron length of any organism described to date at 15 bp, but Stentor also seems to use the standard genetic code, unlike other ciliates. We wish to understand how the regeneration process is coordinated at the molecular level. Some of the details of the regeneration process parallel the events of cell division, and thus we additionally wish to understand whether the cell co-opts certain cell division signaling pathways for regeneration.To identify candidates for RNAi knockdown we analyzed the kinome of Stentor by looking for protein kinase domains among the predicted protein coding genes. Stentor was found to encode more than 2000 kinases, making up 6% of the total protein coding genes. Many of these consist of expansions in mitotic kinase families such as PLKs, NDRs, and NEKs. There are also expansions of families absent in animals and yeast; over 12% of the kinome consists of the calcium-dependent CDPK family, originally identified in plants. We also analyzed additional protein domains found on kinase genes in Stentor, revealing a few novel domain architectures. The most notable example is an adenylate kinase fused to a calcium-dependent protein kinase, with a large region in between containing a AAA+ ATPase and other protein domains. RNAi screening of kinase genes is ongoing, and will ultimately reveal which of these kinases help to coordinate the many different precisely timed cellular events required for successful regeneration. In the future, a better understanding of the mechanisms behind single cell regeneration will have important implications for basic biology as a whole, and will reveal how these single cells can establish and maintain their polarity and cortical organization with such a high degree of precision.

C58 Forward Genetics in *Tetrahymena thermophila* by a Modified Pooled Linkage: Identification of Causative Mutations Related to Cell Division and Ciliogenesis. *Yu-Yang Jiang*[1], Gregory Minevich[2], Jacek Gaertig[1]. 1) University of Georgia, Athens, GA; 2) Columbia University Medical Center, New York, NY.

We developed an improved protocol for identification of causative mutations in *Tetrahymena* using pooled linkage and comparative whole genome sequencing. The workflow involves an outcross of a mutant of interest, uniparental cytogamy of a single F1 clone, pooling of a number of wild-type and mutant F2 clones, whole genome sequencing of mutant and wild-type pools, variant subtractions from the mutant set, and filtering for nitrosoguanidine-induced transition mutations. Based on a few mutants we have analyzed thus far, this workflow reveals either a single or a small number of closely linked variants containing 100% of mutant reads, as candidates for the causative mutation. The procedure can be used for both recessive and dominant alleles. We successfully used this approach for identification of the causative mutation for *cdaI-1*, a temperature-sensitive "hammerhead" mutant, in which the oral primordium and the cleavage furrow shift toward the anterior end, resulting in an incomplete and unequal cell division (isolated by L.M. Jenkins and J. Frankel, University of Iowa; Frankel J., *Eukaryotic Cell* 2008,10:1617-1639). The *cdaI-1* cause is a substitution in a STE20-related kinase encoded by TTHERM_00971920. A wild-type fragment of TTHERM_00971920 rescued the mutant phenotype of the *cdaI-1* cells grown at the restrictive temperature. We applied the same strategy to a more challenging case, identification of a genetic suppressor of a cilia length regulation mutant. A loss of function of a *Tetrahymena* ortholog of the "long flagella 4" (LF4) protein of *Chlamydomonas reinhardtii* leads to longer cilia. LF4 encodes a conserved protein kinase. We aim at identifying the mechanism by which LF4 regulates the length of cilia and its kinase substrate(s). An MTT1-driven cadmium-induced overexpression of LF4 shortens cilia, which leads to cell paralysis, an easily selectable phenotype. A suppressor locus of the LF4 overexpression could encode a phosphorylation substrate or a regulator of LF4. We isolated a number of suppressors of the LF4 overexpression, all of which but one are intragenic (due to a loss of the overproduced LF4 kinase activity). For the single extragenic suppressor, we identified a candidate causative mutation in a conserved ciliary protein gene. We are currently testing whether an introduction of the mutant candidate gene fragment suppresses the consequences of LF4 overexpression.

C59 *Paramecium* as a model to study human ciliopathies: study of a transition zone protein, MKS2. *A. Tassin*, A. Aubusson-Fleury, M. Lemullois, S. Abdallah, J. Cohen, F. Koll. CNRS, Gif sur Yvette , FR.

Ciliogenesis is a multi-step process, including centriole/basal body assembly, maturation and docking to the cell surface where it templates the growth of the cilium. The structural junction between the basal body and the axoneme (transition zone) acts as a filter between the cellular and the ciliary compartment and houses many proteins involved in human ciliopathies. Two transition zone modules (MKS and NPHP modules) are required for cilium formation/function that act together with the Cep290 as a ciliary gate. The transmembrane protein MKS2/TMEM216 protein is one of the MKS module. In order to get a better understanding of the function of MKS2/TMEM216 in motile cilia formation, we

turned to *Paramecium*, which is covered with thousands of motile cilia.

Three *Paramecium* genes encoding three expressed MKS2 proteins were identified in the *Paramecium* genome as a result of whole genome duplication. These three proteins are highly similar. Using GFP-tagged MKS2 expression we demonstrated, using confocal microscopy and electron microscopy, that MKS2 is localized specifically at the transition zone of ciliated basal bodies on Triton-X100 membrane remnants at the level of the axosomal plate, most probably corresponding to the ciliary necklace. To get an understanding of the MKS2 function, we performed two kinds of experiments: knock-down of the three MKS2 genes by bacterial feeding and expression of one *Paramecium* gene carrying one of the two human mutations (R 73L and L114R) causing respectively Joubert and Meckel syndromes. RNAi knocked-down cells showed the presence of cilia and, unlike control cells, all basal bodies were ciliated. This result suggests a deregulation of the ciliogenesis after knocking-down MKS2. Ultrastructural analyses of MKS2-deficient cells revealed an excess of membrane protrusions and an accumulation of vesicles, suggesting defective membrane trafficking in these cells. We demonstrate that introduction of the human mutations in one Paramecium gene leads to mislocalization of the expressed protein.

Altogether, the *Paramecium* model allowed us to localize precisely MKS2 in the transition zone. We demonstrate its involvement in the regulation of ciliogenesis. The mislocalization of the human mutated protein opens the way to understand the mechanisms leading to ciliogenesis defects in the human pathology.

C60 Sfr proteins that transiently localize to the basal bodies during assembly. *Mark Winey*, Alex Stemm-Wolf, Wes Heydeck. Univ Colorado, Boulder, CO.

Basal bodies organize cilia, which are microtubule-based cellular projections responsible for fluid flow and involved in signaling pathways. In Tetrahymena, cilia are arranged along cortical rows that propel the cells and into specialized structures within the oral apparatus that is used for feeding. Basal bodies are comprised of nine-triplet microtubules and hundreds of additional proteins. This structure, and many of the protein components in Tetrahymena are conserved in centrioles of vertebrate cells. We are interested in understanding the assembly of new basal bodies in hopes of revealing mechanisms conserved between basal bodies and centrioles. We have previously reported the basal body functions of the widely conserved component, centrin. Centrin binds a short repetitive sequence first found in the yeast centrosomal protein Sfi1. Human Sfi1 is found at centrioles. Centrioles also contain a related centrin-binding protein, Poc5. We have identified Tetrahymena orthologs of both Sfi1 and Poc5. These proteins are members of a large family of Tetrahymena proteins containing the centrin-binding motif, the Sfr family, on which we have previously reported. Many of the Sfr proteins localize asymmetrically around the basal body and play roles in basal body positioning, a role also demonstrated for centrin. As expected, TtSfi1 and TtPoc5 are found at basal bodies. Interestingly, both proteins only appear transiently at basal bodies during their assembly. Among the many Tetrahymena basal body components that have been examined, this behavior of transient localization is unique to TtSfi1 and TtPoc5. We believe that such localization is suggestive of important roles for these proteins in basal body assembly. TtPoc5 localizes to the basal body distal end, similar to hPoc5 in centrioles, while TtSfi1 localizes asymmetrically and is offset from the basal body microtubule scaffold. Preliminary data from a TtSfi1 macronuclear null strain suggests significant basal body defects. Micronuclear null strains for both TtSfi1 and TtPoc5 have been constructed and the basal body phenotypes of these strains will be examined.

C61 Stabilizing basal bodies to resist asymmetric ciliary forces. *C. G. Pearson*[1], J. Meehl[2], I. M. Cheeseman[3], J. Gaertig[4], M. Winey[2], B. A. Bayless[1]. 1) University of Colorado, Aurora, CO; 2) University of Colorado, Boulder, CO; 3) Whitehead Institute for Biomedical Research, Cambridge, MA; 4) University of Georgia, Athens, GA.

Motile cilia of multi-ciliary arrays undulate in a concerted and asymmetric fashion to produce unidirectional fluid flow. Ciliary forces are resisted and translocated to the cell via radially symmetric basal bodies that remain stable in the face of constant ciliary mechanical forces. The Poc1 protein stabilizes such asymmetric forces by organizing and maintaining the radially symmetric triplet microtubules by linking neighboring triplet microtubules. Specific triplet microtubules at the posterior side of the basal body are preferentially lost in poc1Δ basal bodies. This suggests that asymmetric ciliary beating may contribute increased forces on specific triplet microtubules. We find the Poc1 interacting protein, Fop1 to also stabilize basal bodies. Interestingly, Fop1 localizes asymmetrically to the basal body microtubules that preferentially disassemble in poc1Δ and that are predicted to experience high ciliary forces. Finally, Poc1 and Fop1 alter the level of microtubule glutamylation at triplet microtubules, a modification that is predicted to stabilize microtubules. Like Fop1, basal body microtubule glutamylation is asymmetrically localized and, indeed, required for basal body stabilization. However, Poc1, Fop1 and triplet microtubule post-translational modifications appear to act in separate, but redundant, pathways to stabilize basal bodies against asymmetric ciliary forces.

C62 Organ sculpting in the Drosophila ovary. *D. Bilder*. University of California, Berkeley, Berkeley, CA.

My lab uses Drosophila to investigate the biology of epithelia, the fundamental cell type of metazoan animals. Our interests range from the cell biology of apicobasal polarity to exploiting the fly in order to model mammalian cancer and its associated lethality. In this talk I will focus on our work concerning tissue morphogenesis, exploring how genetic programs create physical forces to specify the distinct organ forms that underlie their functions. Our system is the egg chamber of the Drosophila ovary, a simple acinus-like organ that undergoes elongation coincident with a remarkable tissue-wide rotation. I will discuss our work which combines genetic approaches with imaging and biophysical tools to address issues of microtubule-based symmetry-breaking, planar-polarized cellular organization, and ECM-directed morphogenesis.

C63 Answer to the Puzzle: Why *Paramecium* Pawn Mutants Cannot Swim Backward. *J. L. Van Houten*, J. Yano, S. Lodh, M. S. Valentine. Univ Vermont, Burlington, VT.

More than forty years ago, important new mutants of *Paramecium tetraurelia* were named Pawns (*pw)* for the chess piece because they had lost the ability to swim backward (Kung, Chang et al. 1975). Subsequently they were shown to lack the calcium conductance of the voltage gated calcium channels (Ca_V), which have been shown by electrophysiology to be limited to the ciliary membrane. Otherwise, pawns have normal conductances (Satow and Kung 1974). The genes for *pwA* and *pwB* were identified by complementation 25 years later, but they did not appear to code for channels or subunits. The channels were also elusive until 2012 when we identified three Ca_V1 in the ciliary membrane proteome. We cloned, epitope tagged and expressed these very large (>250 kd) proteins, and showed that they are in the ciliary membrane. These advances allowed us to demonstrate by RNAi that these channels were responsible for most if not all of the backward swimming in depolarizing conditions. This in turn set the stage for answering the question of why *pwA* and *pwB* mutants cannot swim backward. When we express tagged Ca_V1 a, b, or c in wild type cells, these channels can be found in the ciliary membrane. When these tagged proteins are expressed in *pwA* or *pwB* cells, these channels are not detected in the ciliary membrane. However, these channels can be found again in the ciliary membranes, when these mutants are "rescued" with the wild type copy of their mutant gene. Therefore, *pwA* or *pwB* mutants do not swim backward because they do not have Ca_V channels in their cilia where they must reside in order to generate the action potential that drives backward swimming.

C64 Mitochondrial contributions to behavioral and developmental phenotypes in *Paramecium tetraurelia*. *W. E. Bell*, E. A. Thompson, O. M. Emery. Virginia Military Institute, Lexington, VA.

Mitochondria have long been recognized as the primary energy conversion organelle in Eukaryotic cells. More recent studies have illuminated other critical processes in cellular development that involve mitochondria, specifically roles in programmed cell death and cell division. Ciliates have a long history of contributing to our understanding of cellular processes including chemosensory behavior, genetic reorganization, calcium regulation, and ciliary function. Little work has been done on assessing the role of mitochondria in the cellular dynamics of Ciliates. *Paramecium* are excitable cells whose swimming behavior is regulated by membrane potential. Backward swimming responses can be initiated by depolarizing the cell with an increase in external K^+ added to the bathing solution. We have identified a ryanodine-sensitive calcium flux in *Paramecium* that can be observed under such depolarizing conditions. When *Paramecium* were treated with ryanodine receptor antagonists, backward swimming responses initiated by K^+ depolarization were significantly reduced, but not eliminated. Our attempts to localize these channels led not to the endoplasmic reticulum (the expected site of ryanodine receptor/channels) but to mitochondria. Increasing evidence suggests that ryanodine sensitive channels can be found in mitochondria. In addition, recent sequence analysis of the *Paramecium* genome reveals several channels with conserved ryanodine domains, although none with significant overall homology. Since Ca^{2+} is a mediator of the backward swimming response, we used the mitochondrial calcium-sensitive dye Rhod-2 to assess mitochondrial calcium contributions to depolarization. During a K^+ – induced depolarization, Rhod-2 fluorescence in the mitochondria decreased by approximately 30%. When cells were treated with the ryanodine receptor antagonist dantrolene prior to depolarization, the loss of calcium from mitochondria was significantly attenuated. We conclude that mitochondrial calcium stores can extend backward swimming responses in *Paramecium*. We have also utilized MitoTracker dyes to observe mitochondrial phenotypes displayed during autogamy and autophagy in *Paramecium*. Disruption of mitochondrial outer membrane proteins result in increased autophagy and disruption of cell division in *Paramecium*.

C65 Role of Aurora Kinases in Single-Cell Regeneration of *Stentor*. *A. Lin*, W. Marshall. UCSF, San Francisco, CA.

Single cells are capable of developing complex patterns and shapes, but the mechanism by which cells develop shape is largely unknown. *Stentor coeruleus* is a classical model system to study the development and regeneration of cell shape due to the large size ($1mm^3$), the presence of distinct cortical features that define body axes, and most importantly due to the fact that we can surgically manipulate the cells and visualize their regeneration. When the oral apparatus is regenerated in *Stentor*, the macronucleus undergoes shape changes identical to those that occur during cell division at the point in division when a new oral apparatus is formed. This observation has suggested that the timing of distinct steps of oral apparatus formation might be regulated by the same molecules that regulate the timing of division, possibly suggesting that mitosis mechanisms are integral to the processes of regeneration. To study whether there is a connection between regeneration and mitosis, we looked at the role of Aurora kinases in regeneration. Aurora kinase A (AurkA) is a kinase known to regulate spindle assembly. Aurora kinase B (AurkB) is known to guide kinetochore attachment to the spindle. We studied the role of AurkA and AurkB in single-cell regeneration using Aurora kinase inhibitors. We have observed that AurkA inhibitor, MLN8237 and VX-680, accelerates regeneration. Surprisingly, AurkA and AurkB inhibitor, PF03814735, suppresses regeneration entirely. Thus, we show that Aurora kinases are involved in single cell-regeneration and a link between regeneration and mitosis.

C66 Transcriptional dynamics of single-cell regeneration in the ciliate *Stentor coeruleus*. *P. Sood*[1], M. Slabodnick[2], J. G. Ruby[3], S. Reiff[1], S. Roy[4], W. Marshall[1]. 1) UCSF, San Francisco, CA; 2) UNC Chapel Hill, Chapel Hill, NC; 3) Calico, South San Francisco CA; 4) San Francisco State University, San Francisco CA.

The ciliate *Stentor coeruleus* is a remarkable cell–individuals can reach up to 1 mm in length and exhibit great subcellular complexity, including its beautiful wineglass shape. *Stentor* additionally has incredible regenerative abilities: almost any portion of the cell, when removed

through excision, will give rise to a normally proportioned cell with intact subcellular organization. Pioneering studies of *Stentor* elucidated morphological principles of its regeneration (Morgan, 1901; Tartar, 1961), but we know little about the molecular basis of *Stentor*'s regenerative and healing abilities. In general, little is known about regeneration and healing at the level of an individual cell. Because of its large size and its subcellular coordinate system where the anterior and posterior are clearly marked by the oral apparatus and holdfast, respectively, *Stentor* is a very useful system for understanding single cell regeneration and wound repair.

We have recently sequenced and annotated the genome of *Stentor coeruleus*, which will serve as a foundation for future molecular studies. I am currently using RNA-seq to study the transcriptional dynamics underlying the regeneration of the oral apparatus (OA), one of the most prominent features of the cell and a complex organelle composed of thousands of cilia. Upon subjecting cells to sucrose shock, the OA is induced to shed, and 8 hours later a new one forms. We show that genes are organized into five groups of gene expression with distinct temporal signatures, corresponding to the known morphological changes taking place during OA regeneration. During the earliest waves of gene expression, conserved genes involved in centriole production and ciliogenesis are expressed, necessary to replace the OA. Also during these earliest stages, genes involved in RNA metabolism are expressed, including Pumilio, suggesting the requirement for large scale transcriptome alteration through regeneration. The detailed transcriptional time course, in combination with RNAi manipulations, will further reveal the genetic networks that regulate OA regeneration, and will help elucidate the fundamental principles of cell regeneration and healing at the scale of a single cell.

C67 Quantifying HAP2-mediated cellular fusion in a sexual ciliate. *Jennifer F. Pinello*, Donna Cassidy-Hanley, Theodore G. Clark. Cornell Univ., Ithaca, NY.

Although the mechanisms underlying gamete fusion during sexual reproduction remain obscure, recent studies have implicated the conserved transmembrane protein Hapless 2 (HAP2) as an ancestral gamete fusogen. In this regard, genetic disruption of the *HAP2* locus in a variety of eukaryotic organisms, ranging from the ciliated protist *Tetrahymena thermophila*, to flowering plants and malaria parasites, has been shown to lead to a decisive block to fertilization due to the hapless cells' inability to fuse their gametic membranes. To better study the role of HAP2 in membrane fusion we developed a flow cytometry-based assay for the quantification of cellular fusion during *T. thermophila* sexual conjugation. In this assay, complementary *T. thermophila* mating types are first labeled with fluorescent cell tracers (either carboxyfluorescein diacetate succinimidyl ester or cell trace far red) and then allowed to undergo mating. When membrane fusion occurs, the cells in a mating pair actively exchange a portion of their fluorescently-labeled cytoplasmic proteins. After mating, exconjugant cells disengage enabling easy quantification of the overall percentage of cells that exchanged cytoplasm along with the relative amount of cytoplasm transferred using flow cytometry. This assay allowed us to validate our previous finding that HAP2 is necessary for membrane fusion during *T.thermophila* fertilization and provided a rapid way to test for essential functional domains in the HAP2 protein using deletion analysis. We found that disruptions of core domains within the N'-terminus severely restricted membrane fusion events between mating cells, whereas deletions at the C'-terminus had little impact on fusogenicity. Importantly, through the use of homology modelling, we identified a region within the N'-terminal ectodomain that appears to have a high degree of structural similarity to the Dengue virus envelope protein (a class II viral fusogen). This region contains a peptide loop used by the viral protein to perturb target membrane bilayers enough to initiate fusion, allowing viral entry into host cells during infection. We found that deletion of either this 'fusion loop' or the entire Dengue envelope protein homology domain in *T. thermophila* HAP2 completely eliminated cytoplasmic exchange between mating *Tetrahymena* cells. In addition to raising interesting questions regarding the evolutionary origin of HAP2, these results may provide new insights into the mechanistic function of this key developmental protein.

C68 The Role of Extracellular Microvesicles During Conjugation in *Tetrahymena thermophila*. *E. S. Cole*[1], O. Dmytrenko[1], A. Ripeckyj[1], L. Higgins[2], T. Markowski[2], T. Giddings[3], C. Ozzello[3], R. Anderson[3], M. Winey[3]. 1) St. Olaf College, Northfield, MN; 2) Center for Mass Spectrometry & Proteomics, U.MN, St. Paul, MN; 3) MCDB, Univ. Colorado, Boulder, CO.

Presenting author: Eric S. Cole[1]

Tetrahymena thermophila undergo mating that involves adhesion of two cell partners, formation of a mating junction between conjugating cells, and the reciprocal exchange of nuclei across the mating junction. Cell adhesion happens early during pair formation and is followed by cell fusion initiated at hundreds of sites in the future exchange junction. Fusion loci begin as small membrane protrusions that span the intercellular gap, make contact and fuse with membrane of the mating partner. The resulting junction pores expand to create a membrane "curtain" that accommodates bi-directional nuclear exchange. During pore expansion one observes microvesicles extruded into the extracellular space within the mating junction. This study aims to understand the role of these extracellular microvesicles (EMVs). Two hypotheses were explored: 1) EMVs could participate in membrane excavation during pore expansion; 2) EMVs could be involved in signaling between mating cells relevant to advancement of the developmental program. EMVs were isolated by disrupting mating pairs of *T. thermophila* 2-3 hours into conjugation and performing differential high-speed centrifugation. The presence of vesicles was confirmed by negative staining and transmission electron microscopy. Both RNA and protein were detected in purified EMV material. Protein identification from isolated vesicles was performed using capillary liquid-chromatography and tandem mass spectrometry. The results of proteomic analysis (specifically the presence of proteins associated with ubiquitination and formation of multivesicular bodies), were consistent with the hypothesis suggesting that EMVs participate in membrane remodeling during pore-expansion. Proteasome components, typically associated with protein recycling, were also found. Finally, we found Argonaute proteins normally associated with RNAi, suggesting that EMVs could be involved in down-regulating the small "scan" RNAs expressed from the germ-line nucleus early during meiosis. These findings suggest that EMVs represent a complex recycling mechanism targeting cytoplasmic proteins, miRNAs and membrane components during early stages of conjugation. Preliminary evidence also suggests that EMVs secreted early during early conjugation may play a role in cell signaling with

developmental consequences. We are currently pursuing RNA analysis of the EMV contents, and following up on their potential role as mediators of developmental signaling. .

C69 TetraMine and Web Apollo at Tetrahymena Genome Database. *Naomi Stover*, William Chu. Bradley University, Peoria, IL.

Tetrahymena Genome Database (TGD; Ciliate.org) has provided information on the genes, proteins, and genomes of T*etrahymena thermophila* and related ciliate species since 2004. The latest additions to the tool set at this community website are TetraMine and Web Apollo. TetraMine is built using InterMine, an open source software package developed for the integration and analysis of complex biological data. We have incorporated the data from TGD Wiki, our community annotation and data display service, into TetraMine and schedule regular updates to maintain user annotations at both sites. Web Apollo at TGD utilizes the open source Web Apollo package, which allows update of genome sequence annotations by members of the Tetrahymena research community. Web Apollo has been loaded with the final sequences produced from JCVI and is now accepting community annotations of gene start/stop sequences and intron/exon boundaries. Combining these two new tools with the existing resources at TGD, including TGD Wiki and the Student/Unpublished Research Database (SUPRDB), Tetrahymena researchers have access to the advanced search and editing techniques necessary to capture the latest annotations based on published and unpublished research. .

C70 TetraExpress™: A Breakthrough Protein Expression Technology. *Janna Bednenko*[1], Yelena Bisharyan[1], Ashot Papoyan[1], Joanna Cardarelli[1], Alka Agrawal[1], Miguel Pineros[2], Paul Colussi[1], Ted Clark[1]. 1) Tetragenetics Inc. 91 Mystic Street, Arlington, MA, 02474; 2) Robert W. Holley Center for Agriculture and Health USDA-ARS Ithaca, NY 14853.

Membrane proteins are involved in various cellular processes, and many of them serve as therapeutic targets for human diseases. Conventional (mammalian, insect, microbial) cell lines often fail to produce recombinant membrane proteins in large quantities. Tetragenetics, Inc. has developed TetraExpress™, a protein expression platform that takes advantage of the unique biology of *Tetrahymena thermophila*, to overcome the historical limitations of current recombinant systems. TetraExpress™ technology was utilized to tackle an extremely challenging task – rapid production of correctly folded and functional mammalian ion channels in *Tetrahymena* membranes or in purified form. For example, tetrameric (4 x 64 kDa) potassium voltage-gated channel Kv1.3, a therapeutic target implicated in autoimmune disorders, and a 221 kDa sodium voltage-gated channel Nav1.8, a well-validated target for pain treatment, were shown to localize on plasma membrane and in endoplasmic reticulum when expressed in *Tetrahymena*, with the levels of expression 50-100 fold higher than those observed in commercially available mammalian cell lines. Both ion channels were isolated at >90% purity, with the yield of 0.5-2 mg from a liter of culture, and reconstituted into phospholipids. Correct folding and functionality of human Kv1.3 were confirmed by binding assays with fluorescent ShK toxin and voltage clamp recordings in *Xenopus* oocytes injected with Kv1.3 proteoliposomes. Ion channel activity of purified Nav1.8 was demonstrated by electrophysiology in giant unilamellar vesicles using a Nanion Port-a-Patch system. Thus, TetraExpress™ represents an attractive platform that can advance a variety of downstream applications including therapeutic antibody discovery, drug screening, and structure-based drug design. In addition, Tetragenetics, Inc. has partnered with the Tetrahymena Stock Center at Cornell University to facilitate the application of TetraExpress™ to basic and translational research in the form of providing academic community with the opportunity to order starting material for purification of membrane, intracellular or secreted proteins.

C71 Construction of a Gateway fluorescent tagging plasmid system for integration into the *btu1-1* locus. *Jeremy Y. Tee*, Joshua J. Smith. Missouri State University, Springfield, MO.

Tetrahymena thermophila is a ciliate single-celled eukaryote that is extensively studied as a model organism, particularly in the area of chromatin remodeling and DNA repair, where key discoveries have elucidated nucleosome structure and telomerase function. Fluorescence tagging with GFP and RFP is a common way to study protein interactions in *T. thermophila* and typically makes use of recombination of the fusion gene product into the RPL29 locus (exogenous tagging system). GFP/RFP localization along with immunoprecipitation and gene expression studies can elucidate unknown interactions and uncover pathways previously uncharacterized. This project was to develop constructs that are directed to a beta tubulin 1 locus and exogenously express fluorescent-tagged genes (GFP and RFP), while maintaining compatibility with Gateway cloning technology. This will give the ability to visualize protein dynamics while inducing protein expression in live cells, easily moving genes into the plasmid and examining co-localization of tagged genes expressed in different loci. Our plasmids contain a metallothionein (MTT-1) inducible promoter and fluorescence tags of GFP or RFP. Through homologous recombination, genes will be inserted into the beta tubulin 1-1 (*btu1-1*) locus, and following transformation cells are selected by paclitaxel resistance. Of particular interest to this work are proteins involved in DNA repair, in which studying sirtuin and NER-related homologues and making comparisons with previous data provide a benchmark to judge the effectiveness of our plasmid construction.

C72 Research and Cloning of *Tetrahymena thermophila UBE2S* in an Introductory Science Lab. *E. M. Schmoll*, L. N. Allen, J. J. Smith. Missouri State University, Springfield, MO, MO.

The model organism *Tetrahymena thermophila* is used in many modern research experiments due to its simplicity and the numerous homologues that it shares with other more complex organisms. In this freshman honors course, Introduction to the Biomedical Sciences, students with little laboratory experience or background were expected to complete several original research projects throughout the semester, though the primary focus was on learning to analyze, understand, and ultimately clone genes such as *UBE2S* found in *Tetrahymena thermophila*. *UBE2S*, or Ubiquitin Conjugating Enzyme E2S, is a gene present in numerous organisms and active within several cellular processes. The gene aids in a wide variety of functions, most notably mitosis regulation and protein degradation. At the start of the lab,

students were introduced to techniques to isolate and concentrate genomic DNA from *T. thermophila*. The targeted gene was then researched through bioinformatics using several databases and molecular computational tools. This procedure was followed by amplification using polymerase chain reactions, visualization through agarose gel electrophoresis, and cloning using pENTR plasmid TOPO cloning and transformation into *E. coli*. The isolated plasmids were then screened for correct insertion through restriction enzyme digestion. A final gel electrophoresis at the conclusion of the semester confirmed the successful cloning of *T. thermophila UBE2S*. All positive clones were then cryopreserved for use in future research projects in upper division biomedical sciences labs, specifically Recombinant DNA Techniques.

C73 Characterization of the SIRT2 and SIRT3 homologs in *Tetrahymena thermophila*. *Kyle Cook*, Joshua Smith. Missouri State University, Springfield, MO.

The ciliate *Tetrahymena thermophila* contains 18 histone deacetylase (HDAC) homologs, which are responsible for removing acetyl groups from acetylated lysines on histones and other proteins. There is a class of HDACs called Sirtuins (Class III HDACs), which have been implicated in various cellular processes like cancer, diabetes, aging, apoptosis, and transcription regulation. The model organism *Tetrahymena thermophila* has 11 homologs of Sirtuins (four more than humans and other vertebrates even). The scope of this research is to investigate the genes homologous to human SIRT2 and SIRT3, Tetrahymena Histone Deacetylases (THDs) 13, 15, and 16. This study will investigate their expression levels within the cell under various conditions including genotoxic stressors, starvation, and conjugation using qRT-PCR. Localization studies will be done through cloning these genes into plasmids to encode for GFP and 2HA tags. These tagged constructs were then transformed into *T. thermophila* to be used in future studies. Characterizing the function, localization, and the proteins interacting with THD13, THD15, and THD16 could help us better understand the various roles of SIRT2 and SIRT3 histone deacetylases.

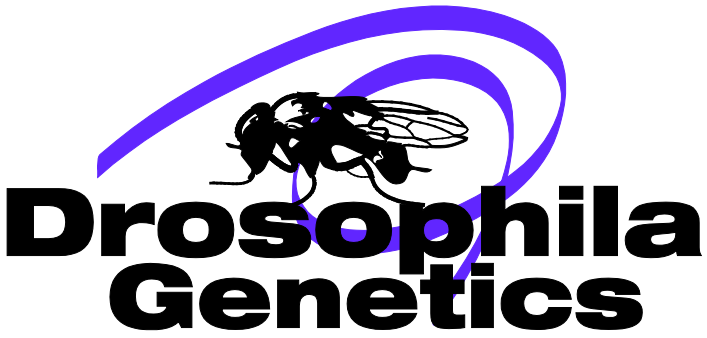
C74 Gene expression changes during infection of *Paramecium caudatum* by *Holospora undulata* bacteria. *C. Kagemann*[1], L. Bright[1], T. Doak[1], O. Kaltz[2], M. Lynch[1]. 1) Indiana University, Bloomington, IN; 2) Institut des Sciences de l'Evolution (ISEM), Montpellier, France.

Holospora is a genus of endosymbiotic bacteria that only grow and divide within one of the two nuclei of their *Paramecium caudatum* hosts. For our study, we focus on *Holospora undulata*, a species that infects the micronucleus of specific *P. caudatum* strains, while other *P. caudatum* strains are resistant. In previous studies, it was shown that the presence of *Holospora* in *Paramecium* benefits the host, especially under stress conditions: certain genes that protect *Paramecium* against both osmotic stress and excess heat are expressed in the presence of *Holospora*. At the same time, infection comes at a significant growth-rate cost to the *Paramecium* host, and we expect that there are host defense mechanisms that are activated. *Holospora* have two forms: a reproductive form and an infectious form. During infection of *P. caudatum, H. undulata* are engulfed and released from the phagosome into the cytoplasm, where they begin to move to the micronucleus. Once the *Holospora* have successfully entered the micronucleus, binary fission occurs to produce reproductive forms of the bacteria. Upon starvation, the reproductive forms transform into infectious forms until they are able to break out of the micronucleus, to find a new host. The movement of *Holospora* within the host suggests that factors such as signaling and membrane trafficking mediate *Holospora* infection. Currently we are focused on determining what genes are associated with membrane trafficking and what stages of infection the resistant strains of Paramecium are blocked at. Total mRNA (RNA seq) from infected and uninfected *Paramecium* will be sequenced to find the total set of genes that are up-regulated during various stages of *H. undulata* infection. To find the genes that are up-regulated at specific time points during infection, we are staging infections and isolating mRNA though the infection cycle.

C75 Towards the Identification of Genomic Targets of MED 31 in *Tetrahymena thermophila*. *C. ThuppuMudalige*[1], J. Garg[2], J. Lambert[3,4], A. Gingras[3], R. Pearlman[2], J. Fillingham[1]. 1) Ryerson University, Toronto, Ontario, Canada; 2) York University, Toronto, Ontario, Canada; 3) Samuel Lunenfeld Research Institute, Toronto, Ontario, Canada; 4) University of Toronto, Ontario, Canada.

Tetrahymena thermophila is a unicellular protist that has a nuclear dimorphism with a polyploid somatic macronucleus (MAC) and a diploid germline micronucleus (MIC) within its single cell. During the vegetative growth of *Tetrahymena*, the two nuclei replicate and divide independently of each other; MIC divides by mitosis and the MAC divides by amitosis. The MIC undergoes meiosis during the sexual life cycle of *Tetrahymena* known as conjugation. The MIC is transcriptionally inactive during the vegetative state and active during meiosis while the MAC is active during vegetative growth and conjugation. The MIC genome is extensively remodeled to form the transcriptionally active MAC genome. The Med31 protein belongs to the transcriptional coactivator complex, Mediator. Med31 protein is small and highly conserved in T. thermophila and most eukaryotes at the amino acid level. While Mediator complexes are well characterized in plants, fungi and animals, it is yet to be characterized in protists. In humans and yeast, Mediator has been shown to interact with the C-terminal domain (CTD) of RPB1 subunit of RNA Polymerase II. Since T. thermophila lacks a canonical CTD in its RPB1 subunit, it raises the question whether the organism has a canonical Mediator. Affinity purification using epitope tag added to the Med 31 and subsequent mass spectrometry analysis represented a potential Mediator complex in T. thermophila. Indirect immunofluorescence has indicated that during vegetative growth, Med 31 localizes to the MAC and to the MIC during meiosis, consistent with function in transcription. To test this hypothesis, we are working towards mapping the genomic targets of Med31 in growth and development using Chromatin Immunoprecipitation combined with next generation sequencing (ChIP-Seq). ChIP is a powerful molecular method where crosslinked chromatin extracts are immune depleted of DNA-protein complexes with specific antibodies against the DNA-binding proteins. The DNA is subsequently analyzed using a variety of methods including direct sequencing. The ChIP method was initially developed for *Tetrahymena* model organism by Dedon et al. (1991) using purified MACs as starting material. We have modified the protocol to use whole cells as starting material and intend to use highthroughput sequencing to identify the genomic targets of Med31.

57TH ANNUAL DROSOPHILA RESEARCH CONFERENCE



Plenary and Platform Session Abstracts

57th Annual Drosophila Research Conference

SCHEDULE AT-A-GLANCE

Wednesday, July 13		
2:00pm-9:30pm	Speaker Ready Room Open	Hall of Cities - Anaheim
7:00pm-9:00pm	Scientific Session: Opening General Session	Crystal Ballroom M
9:00pm-11:00pm	Opening Mixer with Exhibits	Cypress Ballroom
Thursday, July 14		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities -Anaheim
7:45am-10:00am	Genetics and Determinants of Health Joint Plenary Session	Palms Ballroom
8:00am-4:00pm	Exhibits Open	Cypress Ballroom
9:00am-8:00pm	Demo Room: MOD (FlyBase, MGI, SGD, WormBase, Zfin) Demo Room Open	Palms Ballroom Canary 3-4
10:30am-12:30pm	Scientific Session: Plenary Session I	Palms Ballroom Sago/Sabal/Royal
12:30pm-1:30pm	Mentoring Roundtables #1	North Tower - Harbor Beach
12:30pm-1:30pm	Speaking Up for Genetics and Model Organism Research	Crystal Ballroom H
1:30pm-3:30pm	Poster Presentations 1:30pm-2:30pm: Even-numbered posters 2:30pm-3:30pm: Odd-numbered posters	Cypress Ballroom
1:30pm-3:30pm	GeneticsCareers Center and Job Fair	Cypress Ballroom 1C
4:00pm-6:00pm	Concurrent Scientific Sessions: Cell Division and Growth Control Neural Development Organogenesis & Gametogenesis	 Palms Ballroom Sago Palms Ballroom Sabal Palms Ballroom Royal
4:00pm-6:00pm	Plenary Session and Workshop for Undergraduate Researchers	North Tower - Sawgrass
7:45pm-9:45pm	Concurrent Scientific Sessions: Cell Cycle and Cell Death Evolution & Quantitative Genetics I Pattern Formation	 Palms Ballroom Sago Palms Ballroom Sabal Palms Ballroom Royal
10:00pm-11:30pm	*Science Cafe Event	Palms Ballroom Sabal
Friday, July 15		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities - Anaheim
8:00am-9:30am	Concurrent Scientific Sessions: Cell Biology & Cytoskeleton Evolution & Quantitative Genetics II Chromatin & Epigenetics	 Palms Ballroom Sago Palms Ballroom Sabal Palms Ballroom Royal
8:00am-4:30pm	Exhibits Open	Cypress Ballroom
9:00am-8:00pm	Demo Room: MOD (FlyBase, MGI, SGD, WormBase, Zfin) Demo Room Open	Palms Ballroom Canary 3-4

** Ticketed Event*

#TAGC16

Friday, July 15 (continued)		
10:00am-12:00pm	Concurrent Scientific Session: Physiology, Organismal Growth & Aging Techniques & Resources RNA Biology	 Palms Ballroom Sago Palms Ballroom Sabal Palms Ballroom Royal
12:00pm-1:30pm	*Editor's Panel Discussion and Roundtable	North Tower - Harbor Beach
1:30pm-3:30pm	Poster Presentations 1:30pm-2:10pm: "A" poster authors present 2:10pm-2:50pm: "B" poster authors present 2:50pm-3:30pm: "C" poster authors present	Cypress Ballroom
1:30pm-3:30pm	GeneticsCareers Center	Cypress Ballroom 1C
2:00pm-2:45pm	GeneticsCareers Workshop - Nailing the Job Talk	Cypress Ballroom 1B

D80 Organizing the contraction that changes tissue shape. *A. C. Martin*, F. M. Mason, J. S. Coravos. Massachusetts Institute of Technology, Cambridge, MA.

Cells generate forces in tissues to sculpt the myriad of tissue shapes that occur in an organism. An engine that is associated with cell and tissue shape changes in diverse contexts is a dynamic actomyosin meshwork or cortex underlying the plasma membrane. In epithelial cells, contraction of the apical actomyosin cortex can drive apical constriction. How apical actomyosin meshworks contract is not well understood. In particular, the organization and polarity of actin filaments in the cortex are not well defined in contractile epithelial cells. Here, we show that in constricting non-muscle cells of the Drosophila embryo, actin filament pointed ends and myosin are enriched near the center of the apical cortex and actin filament barbed ends are enriched at the junctions. Thus, the apical cortex of non-muscle cells can adopt a polarized structure that topologically resembles a muscle sarcomere. Importantly, we provide evidence that depolarized apical Rho-kinase (ROCK) activity is insufficient to contract actin networks or to promote apical constriction, suggesting that targeted myosin activation by ROCK at the center of the cell apex is required for cell shape change. Polarized ROCK accumulation requires dynamic regulation of its upstream activator RhoA, and we identified an uncharacterized RhoA GAP that is critical for establishing ROCK polarity and apical constriction. ROCK activity is continuously required to sustain its own polarity and also the junctional enrichment of E-cadherin within the apical cortex, demonstrating ROCK's key role in organizing a contractile apical cortex. In conclusion, we identified that establishing ROCK polarity and a sarcomere-like organization to the apical cortex requires a dynamic upstream signaling network that surprisingly involves, not only activation, but inhibition of the RhoA GTPase.

D81 Hox Transcription Factors and their Cell type-specific Role in Development. *I. Lohmann*. Ruprecht-Karls University, Heidelberg, Heidelberg, DE.

The highly conserved and essential class of transcription factors encoded by the *Hox* genes specifies cell fates along the anterior-posterior axis of all bilaterian animals. Besides early patterning functions, Hox proteins are also involved in the morphogenesis of various organs and in the homeostasis of cell lineages in adults. This functional diversity is achieved through a high level of transcriptional specificity, since Hox proteins trigger developmental programs with extreme spatial and temporal resolution, even at the level of single cells. One of the processes controlled by Hox proteins is feeding, a crucial behaviour of all animals, which depends on the rhythmic activity of feeding muscles stimulated by specific brain neurons. We identified the Hox transcription factor Deformed (Dfd) to be expressed and functional in specific neurons and muscles, which are essential for feeding in *Drosophila*. Using genetic, molecular, genomic and behavioural approaches we demonstrate that Dfd is required at subsequent phases in the formation of the feeding unit by directly controlling in a stage-specific manner target genes of motor neuron development, from the initial specification to the establishment of functional synapses. Furthermore, the synchronous regulation of cell adhesion molecules in motoneurons and muscles critical for feeding uncovers Hox proteins as an important factor that might guide the recognition of the interacting synaptic partners. In order to provide vigorous proof for this hypothesis, we use now cell type-specific genomic approaches (INTACT, ChIPseq, RNAseq) to identify the full complement of synaptic molecules in two tissues, the mesoderm and the CNS. By interfering large-scale with synaptic specificity molecules and Hox gene expression, we aim to formulate a Hox-based synaptic specificity code critical for motoneuronal targeting, synaptic wiring and consequently regional motor outputs. Taken together, our multi-scale approach allows us to decipher how the developmentally critical class of Hox transcription factors acquires context-dependent activity and function at the mechanistic level.

D82 Modelling Intellectual Disability Disorders in *Drosophila* - from Genes to Functional Modules and Clinical Applications. *Annette Schenck*, & laboratory. Department of Human Genetics, Donders Institute for Brain, Cognition and Behaviour, Radboud university medical center, Nijmegen, the Netherlands.

Intellectual Disability (ID) disorders are, due to their high frequency and lifetime long expenses, the biggest unmet challenge in clinical genetics and among the largest cost factors of health care in Western countries. ID disorders are largely monogenic, and disease gene identification over the past decade has been highly successful. More than 800 causative genes ('ID genes') have been reported, providing unique stepping stones into the molecular basis of cognition. However, the role of most ID genes, particularly in the nervous system, is poorly understood. A highly efficient model organism is needed to make use of the available information and advance our knowledge in this field.

I will present a synopsis of our work in humans and *Drosophila,* which aims to identify novel pathways and mechanisms that are commonly disrupted in ID and clinically & genetically overlapping Autism Spectrum Disorders. Large-scale phenotyping in *Drosophila* revealed novel roles of ID genes, such as regulation of basal neurotransmission, synapse development and learning. Our data present experimental evidence that ID disorders converge on highly connected, evolutionarily conserved functional modules. Consistent with conserved modularity, *Drosophila* phenotype groups mirror human disease similarity, establishing *Drosophila* as a model for human phenomics. I would also like to discuss how

Drosophila can contribute to disease gene validation in the era of Next Generation Sequencing, and report on our ongoing effort to establish parallel outcome measures in human patients and *Drosophila* models to enhance the translational impact of our model.

Our goal is to provide conceptual advance in understanding of higher brain function in health and disease and to significantly contribute to the development of 'Next Generation' diagnostic and therapeutic strategies for ID and related disorders.

D83 Hippo Signaling in Growth Control and Beyond. *D. Pan*. Johns Hopkins Univ, Baltimore, MD.

The Hippo signaling pathway regulates organ size and tissue homeostasis in diverse species from *Drosophila* to mammals. This pathway comprises several tumor suppressors acting in a kinase cascade that ultimately phosphorylates the oncoprotein Yorkie (Yki) or its mammalian counterpart YAP/TAZ. Much of the recent research on Hippo signaling has focused on identifying upstream inputs into the Hippo kinase cascade, elucidating the mechanisms of Yki/YAP/TAZ in transcriptional regulation, and developing small molecule probes and inhibitors targeting the Hippo pathway. Recent work has also expanded the physiological function of Hippo signaling to many biological processes beyond growth control. I will present recent progress in these areas at the GSA meeting.

D84 Centrosomes and the Spindle Assembly Checkpoint cooperatively ensure proper growth and organization of the developing fly brain by promoting genome stability and viability of neural stem cells. *John Poulton*, John Cuningham, Mark Peifer. University of North Carolina, Chapel Hill.

Proper assembly of the mitotic spindle ensures accurate transmission of genetic material into the two daughter cells. In animals, centrosomes are the primary microtubule organizing centers of mitotic spindles. Intriguingly, most cases of human primary microcephaly (MCPH) are caused by mutations in centrosomal proteins, though the mechanism(s) by which centrosome dysfunction leads to MCPH remains unclear. Although most cells can build mitotic spindles in the absence of centrosomes, we previously demonstrated that acentrosomal epithelial cells of the fly wing disc are prone to mitotic errors and subsequent cell death. In contrast, reports indicate that acentrosomal cells of the developing fly brain do not suffer significant mitotic error or cell death. We therefore explored the underlying basis for the ability of fly brain cells to tolerate centrosome loss. Our data indicate that one reason brain cells avoid detrimental consequences of centrosome loss is the activity of the Spindle Assembly Checkpoint (SAC), which delays anaphase until microtubule-kinetochore attachments form. We found that loss of both centrosomes and the SAC (*mad2,sas-4* double-mutant) disrupts brain development, resulting in dramatically reduced brain size, disorganized architecture, and loss of neural stem cells. Importantly, either single-mutant brains are essentially normal in size and appearance. We also found that cells of these double-mutant brains experience significant increases in mitotic error (~80% of cells are aneuploid/polyploid). Double-mutant brains displayed dramatic increases in rates of DNA damage and cell death, including apoptosis of neural stem cells. Cell death appears to be an important contributor to reduced brain size in these animals, as blocking apoptosis partially rescues double-mutant brain size. Together, our data suggest epithelial cells of the wing imaginal disc are sensitive to mitotic perturbation and quickly eliminated by apoptosis, perhaps because they can be easily replaced. However, irreplaceable central brain neuroblasts may have evolved robust checkpoints to ensure greater tolerance for cellular insults such as aneuploidy.

Drosophila models of microcephaly have been limited because mutations in most fly homologues do not dramatically disrupt brain development. Our data indicate the SAC is one reason fly brains do not mirror the microcephaly observed in humans. This genetic model can now be used to test additional hypotheses regarding the roles of centrosomes and mitotic fidelity during brain normal development and the pathology of microcephaly.

D85 The GATOR2 Complex Uses TORC1 Dependent and Independent Pathways to Regulate Cellular Metabolism. *W. Cai*, Y. Wei, M. Jarnik, J. Reich, M. Lilly. NICHD, National Institute of Health, Bethesda, MD.

TORC1 is a master regulator of metabolism in eukaryotes that responds to multiple upstream signaling pathways. The GATOR complex is a newly defined upstream regulator of TORC1 that contains two sub-complexes, GATOR1, which inhibits TORC1 activity in response to amino acid starvation and GATOR2, which opposes the activity of GATOR1. While the GATOR1 complex has been implicated in a wide array of human pathologies including cancer and hereditary forms of epilepsy, the *in vivo* relevance of the GATOR2 complex remains poorly understood in metazoans. We have defined the *in vivo* role of the GATOR2 component Wdr24 in *Drosophila*. Using a combination of genetic, biochemical, and cell biological techniques we demonstrate that Wdr24 has both TORC1 dependent and independent functions in the regulation of cellular metabolism. Through the characterization of a null allele, we show that Wdr24 is a critical effector of the GATOR2 complex that promotes the robust activation of TORC1 and cellular growth in a broad array of *Drosophila* tissues. Additionally, epistasis analysis between *wdr24* and genes that encode components of the GATOR1 complex revealed that Wdr24 has a second critical function, the TORC1 independent regulation of lysosome dynamics and autophagic flux. Notably, we find that two additional members of the GATOR2 complex, Mio and Seh1, also have a TORC1 independent role in the regulation of lysosome function. These finding represents a surprising and previously unrecognized function of GATOR2 complex components in the regulation of lysosomes. Taken together our data support the model that Wdr24 is a key effector of the GATOR2 complex, required for both TORC1 activation and the TORC1 independent regulation of lysosome acidification and autophagic flux.

D86 Vamana couples Fat signaling to the Hippo pathway. *J. R. Misra*[1,2], K. D. Irvine[1,2]. 1) Howard Hughes Medical Institute; 2) Waksman Institute, Department of Molecular Biology and Biochemistry, Rutgers University, Piscataway, NJ.

Coordinated Growth and morphogenesis is critical to development of tissues of specific size and shape. The protocadherins Dachsous (Ds) and Fat initiate a signaling pathway that regulates both growth, through regulation of Hippo signaling, and morphogenesis, through regulation of planar cell polarity (PCP). Ds-Fat signaling regulates Hippo signaling and PCP by controlling the membrane localization of the atypical myosin

Dachs. Many studies have provided important insights both into how Dachs influences Hippo signaling, and how it influences PCP. In contrast, the mechanism by which Fat signaling actually controls Dachs has remained less well understood. Here we report isolation and characterization the *vamana (vam)* gene as playing a crucial role in regulating membrane localization of Dachs, and in linking Fat to Dachs. Loss of *vam* function decreases growth, whereas overexpression of *vam* promotes growth. These effects are mediated through regulation of the Hippo pathway. Epistasis experiments indicate that *vam* functions genetically downstream of *fat*, as *vam* mutations can suppress lethality, overgrowth and PCP phenotypes elicited by loss of *fat*. Vam localizes to the apical region of epithelial cells in a polarized manner, co-localizing with Dachs, and is required for proper membrane localization of Dachs. Vam physically interacts with both the carboxy-terminal domain of Dachs, and with a region of the Fat intracellular domain that is essential for controlling Hippo signaling and levels of Dachs. Structure-function analysis of Vam argue that Fat negatively regulates Dachs by displacing Vam from the membrane. Our findings establish Vam as a crucial component of the Dachsous-Fat pathway and identify a mechanism for transmission of Fat signaling.

D87 Genetic regulation of cell-fate plasticity in *Drosophila* imaginal discs. *M. I. Worley*, I. K. Hariharan. Univ California, Berkeley, Berkeley, CA.

During the development of an organism, the continued maintenance of determined cell fates is contingent upon the stability of networks of gene expression. Classical experiments using disc transplantation by Ernst Hadorn discovered the phenomenon of transdetermination in regenerating *Drosophila* imaginal discs. Damaged discs do not always regenerate the appropriate structures, and occasionally generate tissue appropriate for other discs or other parts of the same disc. Transdetermination results when cells with one determined state switch to a different determined state. Some signaling pathways, including Wg and Dpp have been shown to be important for this process. However, the underlying events that cause damage-induced transdetermination remain largely unknown, including the genes that regulate this process and the source of cells that change fate.

To address this question, we have conducted a deficiency screen for modifiers of regeneration that lead to the appearance of inappropriate structures following the ablation of the wing pouch by the temporally and spatially controlled expression of the TNF-alpha homolog *eiger.* Using this screen, we identified multiple loci that significantly increase the frequency of transdetermination. From one such locus, we identified the responsible gene as *C-terminal Binding Protein* (*CtBP*), which encodes for a transcriptional co-repressor that interacts with many different transcription factors. Inactivating mutations in the *CtBP* gene result in a high frequency of notum-to-wing transdetermination following damage, indicating that *CtBP* functions to maintain cell-fate identity during imaginal disc regeneration. The notum-to-wing fate change occurs following the generation of a secondary or ectopic blastema in the notum that is dependent on JNK activity. The new wing pouch arises from multiple cells and grows near the boundary that separates the anterior and posterior compartments, which is reminiscent of normal wing pouch development and suggests that cells at specific locations of the notum are more prone to undergo transdetermination into wing-pouch fated cells. In addition, during transdetermination multiple cells of the notum can also re-specify their compartmental identities, which under normal conditions are stably maintained. We have also observed that notum-to-wing transdetermination is significantly enhanced by increased expression of the cytokine Unpaired, and suppressed by reducing STAT activity, thereby demonstrating a role for the JAK/STAT pathway in triggering cell-fate plasticity. Taken together, our studies indicate that CtBP stabilizes cell fates and limits cell plasticity during regeneration and, especially when CtBP levels are reduced, damage-induced activation of JNK and JAK/STAT signaling can promote cell-fate plasticity and respecification.

D88 Oxidative Stress in Oocytes During Mid-Prophase Induces Premature Loss of Cohesion and Chromosome Segregation Errors. *A. T. Perkins*, T. M. Das, E. M. Morse, S. E. Bickel. Dartmouth College, Hanover, NH.

In humans, errors in meiotic chromosome segregation that produce aneuploid gametes increase dramatically as women age, a phenomenon termed the maternal age effect. During meiosis, cohesion between sister chromatids keeps recombinant homologs physically attached and premature loss of cohesion can lead to missegregation of homologs during meiosis I. A growing body of evidence suggests that meiotic cohesion deteriorates as oocytes age and contributes to the maternal age effect. One hallmark of aging cells is an increase in oxidative damage caused by reactive oxygen species (ROS). Therefore, increased oxidative damage in older oocytes may be one of the factors that lead to premature loss of cohesion and segregation errors. To test this hypothesis we used a Gal4/UAS RNAi strategy to induce oxidative stress in Drosophila oocytes and measured the fidelity of chromosome segregation during meiosis. Knockdown of the ROS scavengers SOD1 (cytoplasmic) or SOD2 (mitochondrial) caused a significant increase in segregation errors. This increase occurred primarily because recombinant chromosomes missegregated during meiosis I at a significantly greater frequency, consistent with oxidative damage causing premature loss of meiotic cohesion. FISH analysis confirmed that arm cohesion is disrupted in SOD knockdown genotypes. Together these results provide the first *in vivo* demonstration that oxidative stress during meiotic prophase induces chromosome segregation errors and support the model that accelerated loss of cohesion in aging human oocytes is caused, at least in part, by oxidative damage.

D89 Yorkie, a transcriptional co-activator that regulates growth, also functions at the cell cortex to promote cytoskeletal tension. *Jiajie Xu*[1], Pamela Vanderzalm[2], Ting Su[1], Misha Ludwig[1], Richard Fehon[1]. 1) University of Chicago, Chicago, IL; 2) John Carroll University, University Heights, OH.

Yorkie (Yki) is well known as a transcriptional co-activator that functions downstream of the Hippo pathway to positively regulate transcription of genes that promote tissue growth. Recent studies have shown that increased cytoskeletal tension activates both Yki and YAP (a mammalian orthologue of *Drosophila yki*), resulting in increased nuclear localization and tissue growth. To better understand the effects of tension, as well as upstream pathway activity, on Yki function in living tissues, we generated a tagged *yki* transgene that is expressed at

endogenous levels. Using this Yki reporter, we find that tension, generated either mechanically or genetically, results in increased nuclear Yki accumulation in the wing epithelium. Unexpectedly, we also find that tension induces Yki to accumulate in the cell cortex at the apical junctional region (AJR) in live cells. To ask if Yki might have a previously unrecognized, non-transcriptional function at the cell cortex, we added a myristoylation signal to the Yki N-terminus to tether Yki to the membrane. Remarkably, when expressed transgenically in the wing myristoylated Yki promotes cytoskeletal tension and folding in the epithelium by activating the *Drosophila* myosin regulatory light chain Spaghetti squash (Sqh). In addition, we found that activating Yki by genetically inactivating the Hippo pathway also causes Yki to accumulate at the AJR and increases Sqh activity. Conversely, depletion of *yki* using RNAi resulted in reduced Sqh activity. Based on these results, we suggest that active Yki functions in a feed forward 'amplifier' loop that promotes cytoskeletal tension, and thereby greater Yki activity, in response to tension such as that generated in the peripheral regions during imaginal disc growth. We are testing this hypothesis by generating *yki* alleles that lack the ability to activate Sqh, and are also dissecting the molecular mechanism underlying this novel function of Yki.

D90 Notch signaling promotes cell proliferation and controls cell identity in developing imaginal ring cells. *S. Yang*, W. Deng. Florida State University, Tallahassee, FL.

Imaginal rings are larval tissues composed of precursor cells that are essential for the formation of adult foreguts, hindguts and salivary glands. Imaginal ring cells are specified from subsets of the ectoderm at embryonic stage. These cells kept quiescent until late second instar and then undergo rapid cell proliferation during the third instar to attain adequate number of cells that will replace apoptotic larval tissues for adult organ formation. Therefore, cell specification, cell identity maintenance and cell proliferation are tightly associated with the development of imaginal rings, but the regulatory mechanisms are poorly understood. Here, we show that Notch signaling is activated in all three imaginal rings from middle embryonic stage to early pupal stage. Our mutant clonal analysis, knockdown and gain-of-function studies indicate that canonical Notch signaling positively is required and sufficient for cell proliferation in all three imaginal rings during the third instar. We also found that Serrate (Ser) but not Delta (Dl) from neighboring cells is the ligand for Notch activation. Ser predominantly *trans*-activates Notch signaling, but also plays a role in *cis*-inhibition to modulate the level of Notch activity. In addition, we demonstrate that Notch signaling is required for cell specification of all imaginal ring cells from primordium at middle embryonic stage and maintains imaginal ring cell identity during first and second instars. Taken together, our studies indicate that Notch acts as a growth-promoting and development-regulating signal in *Drosophila* larval precursor cells, and that imaginal rings are excellent *in vivo* models to decipher how Notch regulates cell proliferation and organogenesis.

D91 Regulating the regulator of cell cycle, Xpd. *R. NAG*, S. NIGGLI, S. GUIMARAES, B. SUTER. UNIVERSITY OF BERN, BERN, CANTON OF BERN, CH.

Xpd, a DNA helicase, classically known to play a role in transcription and nucleotide excision repair, has also been shown to be involved in cell cycle regulation in young Drosophila embryos (Chen et al., 2003, Li et al., 2010). Xpd has been shown to perform its functions as part of the TFIIH, the Cdk Activating Kinase (CAK) complex and the Crumbs/Galla-2 complex (Yeom et al., 2014). In our study of early Drosophila embryos, we report the interaction of Xpd with the Mms19 protein, which together form a complex consisting of Xpd/Mms19/Galla-2. Further investigations of the *mms19* gene revealed that the knockdown of the maternal *mms19* product in early embryos causes mitotic defects. We observed mainly chromosome segregation defects and spindle abnormalities. Interestingly, homozygous *mms19* mutants fail to develop imaginal discs during the larval stages, a typical phenotype of a loss-of-function mutation in a mitotic gene. Epistasis studies conducted in these larvae led to the rescue of some of the *mms19* phenotypes by the over expression of CAK. Our research indicates that the interactions of Xpd with Mms19 and/or Cdk7 at different stages of the cell cycle are crucial for the cell to undergo normal cell divisions.

D92 Formin3 regulates dendritic architecture via microtubule stabilization and is required for somatosensory nociceptive behavior. *R. Das*[1], A. A. Patel[1], H. M. Bobo[1], J. M. Harris[1], I. Foldi[2], S. Nanda[3], G. A. Ascoli[3], J. Mihaly[2], D. N. Cox[1]. 1) Georgia State University, Atlanta, GA; 2) Institute of Genetics, Szeged, Hungary; 3) George Mason University, Fairfax, VA.

The cytoskeleton is a defining component of eukaryotic cells including neurons and constitutes the foundation of their inner architecture. Despite many significant advances, it is not yet clear how genetically encoded growth rules are dynamically expressed through the local molecular interactions of cytoskeletal components driving dendritic arborization. Cell-type specific dendritic morphologies emerge via complex growth mechanisms modulated by intrinsic signaling involving transcription factors that mediate neuronal identity, as well as functional and morphological properties of the neuron subtype. Thus, in pursuit of identifying a convergent nodal point of combinatorial transcription factor regulation and modulation of the actin and microtubule cytoskeletons in *Drosophila* dendritic arborization (da) sensory neurons, we found that Formin3 (Form3) is a target of both Cut and Knot, two key transcription factors known for their modulatory role of cytoskeletal components. To investigate the role(s) of *form3* in dendritic development, we conducted *in vivo* neurogenetic analyses of loss-of-function mutants, together with Form3 overexpression analyses and immunohistochemistry (IHC) studies of Form3 localization. Intriguingly, among the six *Drosophila* Formins, only disruptions in *form3* function elicit strong defects on dendritic development, whereas disruption of the other five fly Formins had mild or no effect on class IV (CIV) dendrite morphogenesis. We demonstrate that Form3 is differentially expressed in da neuron subclasses and functions cell-autonomously in CIV neurons to stabilize distal higher order branching along the proximal-distal axis of dendritic arbors. Furthermore, live confocal imaging of cytoskeletal multi-fluor reporters and fixed tissue IHC analyses reveal that *form3* mutation leads to collapse of the microtubule (MT) cytoskeleton. Biochemical analyses indicate Form3 directly interacts with MTs via the FH1/FH2 domains. Form3 is predicted to interact with two ATAT1 alpha-tubulin N-acetyltransferases suggesting it may promote MT stabilization via acetylation. Analyses of acetylated dendritic MTs supports this hypothesis as defects in *form3* lead to reductions, whereas overexpression promotes increases in MT acetylation. Neurologically, *INF2* (the human ortholog of *form3)* mutations have been demonstrated to be causative

for dominant intermediate Charcot-Marie-Tooth (CMT) disease E. CMT sensory neuropathies lead to distal sensory loss resulting in a reduced ability to sense heat, cold, and pain. Intriguingly, disruption of Form3 function in CIV nociceptive neurons results in a severe impairment in nocifensive behavior in response to noxious heat suggesting that *INF2* and *form3* may share a primordial function in regulating nociception.

D93 Heparan sulfate proteoglycans promote dendritic growth of *Drosophila* sensory neurons through receptor protein tyrosine phosphatase Ptp69D. *Amy Poe*, Lingfeng Tang, Bei Wang, Chun Han. Weill Institute for Cell and Molecular Biology, Department of Molecular Biology and Genetics, Cornell University, Ithaca, NY.

Dendrite morphogenesis is essential for the formation of neural circuitry. As dendritic architectures profoundly affect neuronal functions, establishing cell type-specific dendrite morphologies is critical for diverse functions of neurons. A key question in dendrite morphogenesis is how extracellular cues direct dendritic patterning. In particular, many so-called "space filling" neurons have the capacity to extensively and uniformly cover the receptive field. Whether these neurons are self-sufficient in innervating their target fields or they rely on extracellular permissive signals is unknown. To answer this question, we use *Drosophila* class IV dendritic arborization (da) neurons as a model system. The dendrites of class IV da neurons completely and non-redundantly cover the larval epidermis. Using RNA interference (RNAi) in epidermal cells, we discovered that the innervation of receptive fields by class IV da neurons require epidermis-derived heparan sulfate proteoglycans (HSPGs), a type of extracellular or membrane-associated glycoproteins. This suggests the existence of an extracellular permissive signal for the dendritic growth of class IV da neurons. Our loss-of-function (LOF) analyses of HSPG genes demonstrated that Syndecan (Sdc) and Dally act redundantly to promote the local growth of high order dendritic branches. By conducting time-lapse imaging, we found that HSPGs are not required for short-term dynamics of terminal dendrites but are necessary for stabilizing dendritic microtubules. Rather than promoting dendritic growth by binding to secreted ligands, our data suggest that HSPGs themselves may serve as the permissive signal. Supporting this hypothesis, we found that receptor protein tyrosine phosphatase Ptp69D, a HSPG receptor expressed in class IV da neurons, is required for the growth of and the microtubule stabilization in class IV da dendrites. Together, our results demonstrate that HSPGs are permissive signals for dendritic growth of space-filling class IV da neurons.

D94 *nejire*-mediated transcriptional regulation of dendritic growth and arborization complexity. *S. G. Clark*, A. A. Patel, J. Lott, S. Bhattacharya, D. N. Cox. Georgia State University, Atlanta, GA.

nejire (*nej*), the *Drosophila* homolog of CREB Binding Protein, has been studied as a regulator of embryonic pattern formation and of circadian rhythms in adult *Drosophila*, however its potential role in dendritic development remains largely unexplored. In a genetic screen for transcriptional regulators of dendritic development in complex arbor neurons, we identified *nej* as a novel regulator of dendritic development. Here, we investigate the role of *nej* as an essential regulator of dendritic growth and branching complexity using dendritic arborization (da) sensory neurons of the *Drosophila* larva. Loss-of-function studies implicate *nej* in regulating dendritic growth and proximal-distal branch order distribution as disruptions lead to a reduction in dendritic field coverage and a shift from distal terminal branching complexity to more proximal dendritic tufting in class IV (CIV) da neurons. Conversely, *nej* overexpression in CIV neurons leads to severe disruption in higher order dendritic growth and branching whereby nearly all branches above second order are absent. To identify putative functional domains required for *nej*-mediated arbor development, domain-specific deletion constructs were expressed in CIV neurons revealing that deletion of the N-terminal region (ΔNZK) leads to defects that largely phenocopy those observed with *nej* knockdown, whereas deletion of the C-terminal region (ΔQ) generates phenotypic defects consistent with overexpression of full-length *nej*, albeit even more severe. To gain further insight into *nej*-mediated signal transduction in dendritic development, we have investigated putative *nej* interacting molecules. These analyses reveal a regulatory relationship between *nej* and *dar1*, a transcription factor known to affect dendritic growth by regulation of the microtubule severing protein Spastin. *dar1* overexpression produces a phenotype that is strikingly similar to that of *nej* knockdown and changes in *nej* expression cause shifts in the subcellular localization of Dar1 in CIV neurons. We also demonstrate a potential relationship between *nej* and *shaggy* (GSK3), which is known to affect microtubule dynamics in axons, as the expression of a kinase-dead *shaggy* results in CIV dendritic morphology that is phenotypically nearly identical to that caused by expression of the *nej* ΔNZK construct. Furthermore, our analyses suggest potential links to the NF-κB pathway, as *relish* overexpression phenocopies *nej* knockdown and *relish* knockdown causes a reduction in branching complexity that is phenotypically consistent with *nej* overexpression. Collectively, these analyses extend our understanding of molecular mechanisms of transcription factor activity at a class-specific level and how this regulation contributes to specification of distinct neuronal morphologies that underlie the establishment of complex neural networks.

D95 A Functionally Conserved Gene Regulatory Network Module Governing Olfactory Neuron Diversity. *S. Barish*[1], Q. Li[2], S. Okuwa[1], A. Maciejewski[1], A. Brandt[3], D. Reinhold[4], C. Jones[3], P. Volkan[1]. 1) Duke University, Durham, NC; 2) Stanford University, Palo Alto, CA; 3) University of North Carolina, Chapel Hill, NC; 4) Clark University, Worcester, MA.

Drosophila uses 50 different olfactory receptor neuron (ORN) classes that are clustered in combinations within distinct sensilla subtypes to decipher a complex chemical environment. Each sensilla subtype houses 1-4 ORN identities that arise through asymmetric divisions from a single multipotent sensory organ precursor (SOP). How each class of SOPs acquires a unique differentiation potential that accounts for ORN diversity is unknown. Here, we show that Rn, along with BarH1/H2 (Bar), Bric-à-brac (Bab), Apterous (Ap) and Dachshund (Dac), is part of a conserved proximodistal (PD) gene regulatory network module that patterns the antennal disc into seven concentric rings and diversifies SOP identities. Each ring expresses a unique combination of the aforementioned transcription factors, and encodes the differentiation potentials for a limited number of sensilla subtypes. Genetic perturbations of the network lead to predictable changes in ORN diversity. These data suggest that the diversification of precursor fields by the prepatterning network is the first step to neuronal diversification, followed by SOP selection

by proneural genes, and Notch-mediated neurogenesis. As each step operates in a context-dependent manner, deployment of the same transcription factor network module may regulate neuronal diversity in parallel systems with completely different fate outputs.

D96 Developmental programs and olfactory receptor signaling in structural and functional development of *fruitless* positive olfactory neurons. *P. C. VOLKAN*, C. E. HUESTON, D. OLSEN, Q. LI, S. OKUWA, J. WU, B. PENG. DUKE UNIVERSITY, DURHAM, NC.

During development, sensory neurons must choose identities that allow them to detect specific signals and connect with appropriate target neurons. Ultimately, these sensory neurons will successfully integrate into appropriate neural circuits to generate defined motor outputs, or behavior. This integration requires a developmental coordination between the identity of the neuron and the identity of the circuit. The mechanisms that underlie this coordination are currently unknown. Here we describe two modes of regulation that coordinate the sensory identities of Drosophila melanogaster olfactory receptor neurons (ORNs) involved in sex-specific behaviors with the sex-specific behavioral circuit identity marker fruitless (fru). The first mode involves a developmental program that coordinately restricts to appropriate ORNs the expression of fru and two olfactory receptors (Or47b and Ir84a) involved in sex-specific behaviors. This regulation requires the chromatin modulatory protein Alhambra (Alh). The second mode relies on the signaling from the olfactory receptors through CamK and histone acetyl transferase p300/CBP to maintain ORN-specific fru expression. Our results highlight two feed-forward regulatory mechanisms with both developmentally hardwired and olfactory receptor activity-dependent components that establish and maintain fru expression in ORNs. Such a dual mechanism of fru regulation in ORNs might be a trait of neurons driving plastic aspects of sex-specific behaviors.

D97 Inhibition of mitochondrial calcium entry in mushroom body neurons during pupariation causes memory impairment and neuronal structural defects in adult flies. *Ilaria Drago*, Ronald Davis. The Scripps Research Institute-Scripps Florida, Jupiter, FL.

Mitochondria are one of the key players in cellular calcium signaling. Upon an increase in cytoplasmic calcium concentration, the mitochondrial calcium uniporter protein complex is activated allowing calcium to enter the mitochondrial matrix. Mitochondrial calcium entry is critical to a plethora of cellular processes including cytoplasmic calcium buffering, regulation of ATP production, apoptosis and autophagy (Kamer and Mootha, 2015).

Components of the mitochondrial calcium handling machinery were found among the hits of a pan-neuronal RNAi screen performed to discover new genes that are required for normal olfactory memory formation in *Drosophila* (Walkinshaw et al., 2015). Subsequent olfactory conditioning experiments showed that inhibiting mitochondrial calcium entry specifically in the mushroom bodies (MB) causes a memory impairment without altering the ability of the flies to learn. Surprisingly, impairing mitochondrial calcium entry in MB only during pupariation - but not during earlier developmental stages or adulthood- recapitulates the phenotype observed when mitochondrial calcium entry is impaired both during development and adulthood. Global structural analyses of the MB in flies where the mitochondrial calcium uniporter is silenced failed to reveal any gross structural defect. Nevertheless, a more detailed analysis revealed that the number of synaptic vesicles in the MB of these flies is significantly decreased when compared to control flies. Moreover, single MB neuron analyses using photoactivatable GFP showed that the axonal length of a specific sub-population of MB neurons is increased when mitochondrial calcium entry is inhibited.

Our results uncover a novel role for mitochondria calcium handling *in vivo* and reveal a relationship between developmental mitochondrial calcium homeostasis, olfactory memory formation, and MB neuronal structure in adult flies.

D98 Syncrip regulates *prospero* stability during neuroblasts division and differentiation. *Lu Yang*[1], Francesca Robertson[1], Aino Jarvelin[1], Tamsin Samuels[1], Yoav Arava[2], David Ish-Horowicz[3], Ilan Davis[1]. 1) University of Oxford, Oxford, United Kingdom; 2) Department of Biology Technion, Israel Institute of Technology, Haifa, Israel; 3) MRC for Molecular Cell Biology, University College London, London, United Kingdom.

Brain development depends on precise regulation of the balance between neural stem cell proliferation and differentiation. One of the most extensively studied regulators of neural stem cells is Prospero (Pros). In *Drosophila* larval brains, it had been demonstrated that Pros level must be precisely regulated both spatially and temporally to allow correct brain development. However, how this is achieved remains unknown. In the current study, we directly test whether differential Pros level is regulated at transcriptional or post transcriptional level by performing *in situ* using a combination of intron and exon probes against *pros.* We showed although Pros is expressed at low level in neuroblasts (NB) and gradually increase in level in NB progeny over time, *pros* mRNA is transcribed at equal level in all cells types. This suggests post-transcriptional regulation is likely to be involved in achieving the differential Pros expression. We have identified a novel interactor of *pros* mRNA - Syncrip. In *syp* mutants, we observed significantly enlarged optic lobes along with increased number of nBs and increased nB division rate. Both Pros protein and mRNA level are decreased in *syp* mutants. Surprisingly, our data showed *pros* transcription is not affected in *syp* mutants but the stability of the RNA is significantly decreased. Mapping the poly(A) site of *pros* mRNA revealed *pros* mRNA harbours two distinct 3'UTR variants, one 3 kb and one 15 kb 3'UTR with the 15 kb UTR being the predominant form. By using *in situ* probes directly against the 15 kb 3'UTR, we showed the 15 kb variant is only transcribed in mature neurons and this is accompanied by an up-regulation of Pros protein. Interestingly, both forms for *pros* mRNA are made in *syp* mutants but not maintained. From the current data, we propose a Syncrip dependent model for regulating differential Pros protein expression through choice and maintenance of 3'UTR variants.

D99 Spontaneous grooming and other activity phenotypes resulting from Neurofibromin loss of function in Drosophila. *L. B. King*[1], M. Koch[1,2], K. Murphy[1], Y. Velazquez[1], W. W. Ja[1], S. M. Tomchik[1]. 1) The Scripps Research Institute, Jupiter, FL; 2) Center for the Biology of Disease, VIB, Leuven, Belgium.

Neurofibromatosis I is a common genetic disorder that results in tumor formation and predisposes individuals to a range of cognitive/behavioral symptoms, including deficits in attention, visuospatial skills, learning, language development, sleep, and autism spectrum

disorder-like traits. The *nf1*-encoded neurofibromin protein (Nf1) exhibits high conservation, from the common fruit fly, *Drosophila melanogaster*, to humans. *Drosophila* provide a powerful platform to investigate the signaling cascades upstream and downstream of Nf1, and the fly model exhibits similar behavioral phenotypes to mammalian models. In order to understand how loss of Nf1 affects motor behavior in flies, we combined traditional activity monitoring with video analysis of grooming behavior. In *nf1* mutants, spontaneous grooming was increased up to 7x. This increase in activity was distinct from previously-described dopamine-dependent hyperactivity, as dopamine transporter mutants exhibited slightly decreased grooming. Finally, we found that relative grooming frequencies can be compared in standard activity monitors that measure infrared beam breaks, enabling the use of activity monitors as an automated method to screen for grooming phenotypes. Overall, these data suggest that loss of *nf1* produces excessive activity that is manifested as increased grooming, providing a platform to dissect the molecular genetics of neurofibromin signaling across neuronal circuits.

D100 Mediator subunit *skuld* is required sex specifically for ovary development. *H. Sultana*, H. Yang, B. Oliver. NIDDK, National Institutes of Health, Bethesda, MD.

Organogenesis requires spatio-temporal regulation of gene expression. We use development of the female gonads as a model to understand gene expression regulation. In *Drosophila melanogaster*, female gonads consist of a pair of ovaries, which contain both germ cells and somatic cells. Somatic cells are indispensible for proper growth, differentiation, and sex determination of germ cells. Here we took two independent approaches to identify the genes that potentially affect germ cells nonautonomously. In the first approach, we performed a reverse genetic screen using the UAS-Gal4 system to knockdown genes in Traffic Jam positive somatic cells and screen for female sterility. We tested 1,119 genes in this screen and found 169 to be female sterile. In the second approach, we performed transcriptional profiling of the anterior ovariole consisting of germaria and round previtellogenic egg chambers, which are regions with close contact between germ cells and somatic cells. We performed RNA-Seq on 12 biological replicates of anterior ovariole and compared it to whole ovary. We found expression of 3,999 genes enriched in anterior ovariole compared to whole ovary *(Padj<= 0.05)*. Out of these 73 were female sterile in the genetic screen. We selected 67 genes for further characterization that were either female sterile in the genetic screen or were enriched in the anterior ovariole RNA-Seq experiment. Development of both testes and ovaries was affected in the knockdown of 18 genes, whereas knockdown of three genes *skuld*, *broad* and *misshapen* gave ovary specific phenotypes. *skuld (skd)* is a component of the kinase domain of the mediator complex along with *kohtalo (kto), Cyclin C* and *Cdk8*. *skd* knockdown in somatic cells of the gonad resulted in developmental arrest of the ovaries but not the testes. In L3 larval ovaries, germ cells were not present in a zone like control ovaries but were spread across the ovary suggesting a nonautonomous role of *skd* in germ cell organization. *skd* and *kto* have been shown to function in a similar context in several tissues. When we knocked down *kto* we found an effect on the development of both testes and ovaries. Both at L3 and adult stages, mutant ovaries for *skd* and *kto* looked similar. However, *kto* mutant testes were thin and sterile at 29°C unlike *skd* mutant testes, which were fertile. We cross-validated this phenotype by investigating gene expression of *skd* and *kto* in ovaries vs. testes from different publically available RNA-Seq datasets. We found significant enrichment of *skd* expression (*Padj<0.0001*) in the ovaries compared to the testes whereas *kto* is expressed at comparable levels in both male and female gonads. Our study suggests differences in function of mediator components *skd* and *kto* in gonad development and also proposes a sex specific role of *skd* in ovary development.

D101 Neuropeptide-dependent control of female germline stem cell proliferation after mating in *Drosophila melanogaster*. *T. Ameku*[1], Y. Yoshinari[1], S. Kondo[2], R. Niwa[1,3]. 1) University of Tsukuba, Tsukuba, Ibaraki, JP; 2) National Institute of Genetics, Mishima, Shizuoka, JP; 3) Japan Science and Technology Agency, Kawaguchi, Saitama, JP.

Gametogenesis and mating are two essential components of animal reproduction. Gametogenesis must be modulated by the need for gametes, yet little is known of how mating, a process that consumes gametes, may modulate the process of gametogenesis at the cellular level.

Here we report that mating stimulates female germline stem cell (GSC) proliferation via neuronal and endocrine systems in *Drosophila*. Mating-induced GSC proliferation is not simply owing to the indirect effect of emission of stored eggs, but rather is caused by a sex peptide (SP) and its receptor SPR, the canonical pathway to transduce the signal from male seminal fluid to female flies. We also identify ecdysteroid, the principal insect steroid hormone, as a key mediator of GSC proliferation after mating. Importantly, ovarian ecdysteroid biosynthesis is induced by neuronal SP signaling, suggesting that GSC proliferation is under the control of the characterized neuroendocrine system in response to an external stimulus, mating.

Previous studies and our own analysis, however, suggest that *SPR* gene is not expressed in GSC cells or GSC niche cells. Therefore, neuroendocrine mechanisms transmitting SP signals to GSCs still remain to be elucidated. To address this question, we carried out a transgenic RNAi screen to search genes that are required for transmits SP signals to GSCs. We examined GSC phenotypes in females in which a wide variety of membrane receptor genes in neurons as well as GSC niche cells have been knocked down. We identify 50 candidate genes, including 13 neuropeptide receptors, which are potentially involved in controlling mating-induced GSC proliferation. We also show that genes encoding ligands for some of the neuropeptide receptors are expressed in the midgut and are required for mating-induced GSC proliferation. Moreover, overexpression of the ligand genes are sufficient to induce GSC proliferation. These results suggest that neuropeptide signaling mediates mating-induced GSC proliferation via the hormonal interactions among different tissues. Our work reveals a novel role of neuropeptide signaling in regulating GSC proliferation that coordinates gametogenesis in response to the stimulus of mating.

In this presentation, the relationship between SP, ecdysteroid and neuropeptide in regulating GSC will be discussed.

D102 Electron Transport Chain Remodeling by GSK3 during Oogenesis Connects Nutrient State to Reproduction. *Matthew Sieber*[1], Michael Thomsen[1], Allan Spradling[1,2]. 1) Carnegie Institution for Science, Baltimore, MD; 2) Howard Hughes Medical Institute.

Reproduction in all systems is heavily influenced by nutrition and the metabolic state of the organism. Furthermore, metabolic syndrome is thought to be a major factor in a number of reproductive disorders in humans. For example, PolyCystic Ovary Syndrome (PCOS), the most common cause of infertility in women, is strongly associated with type-2 diabetes and obesity. However, despite these intimate relationships, the precise metabolic mechanisms that support reproduction remain poorly defined. Interestingly, as *Drosophila* eggs develop, nutrients accumulate in the germline in a coordinated stepwise manner. This stepwise accumulation, in conjunction with the advanced genetics available in *Drosophila*, provides an excellent system to investigate the roles of energy homeostasis during oocyte development and reproduction.

Using a combination of metabolomics, proteomics, and molecular genetics we have found that developing *Drosophila* follicles undergo a major metabolic transition after stage 10 that leads to massive glycogen accumulation. This transition leads to shift in the balance of glycolysis and gluconeogenesis that results in the build up of several glycolytic/gluconeogenesis intermediates as well as a subset of TCA intermediates. Intriguingly, this shift in carbohydrate metabolism is the result of germline mitochondria entering into a state of respiratory quiescence in the late stages of oogenesis. Mitochondria enter respiratory quiescence as a result of a dramatic remodeling of the electron transport chain (ETC). ETC remodeling and mitochondrial quiescence are triggered by a reduction in insulin/akt signaling, and mediated by glycogen synthase kinase 3 (GSK3). Using proteomic analysis of isolated germline mitochondria we have found that GSK3 induces respiratory quiescence by promoting a global shift in mitochondrial protein content. Intriguingly, we observed a similar glycogen and ETC remodeling in Xenopus oocytes, suggesting that remodeling the ETC and inducing carbohydrate storage are important and conserved aspects of the terminal stages of egg production. Collectively, our data indicates that GSK3-mediated ETC remodeling is a novel, but highly conserved, mechanism of mitochondrial regulation. Furthermore, these data provide valuable insights into the mechanistic links between metabolic syndrome and many reproductive disorders.

D103 The mitochondrial outer membrane protein MDI promotes local protein synthesis and mtDNA replication. *Y. Zhang*, Y. Chen, M. Gucek, H. Xu. NHLBI, Bethesda, MD.

Early embryonic development features rapid nuclear DNA replication cycles, but lacks mtDNA replication. To meet the high-energy demands of embryogenesis, mature oocytes are furnished with vast amounts of mitochondria and mtDNA. However, the cellular machinery driving massive mtDNA replication in ovaries remains unknown. Here we describe a *Drosophila* AKAP protein, MDI that recruits a translation stimulator, La-related protein (Larp), to the mitochondrial outer membrane in ovaries. The MDI-Larp complex promotes the synthesis of a subset of nuclear-encoded mitochondrial proteins by cytosolic ribosomes on the mitochondrial surface. MDI-Larp's targets include mtDNA replication factors, mitochondrial ribosomal proteins and electron-transport-chain subunits. Lack of MDI abolishes mtDNA replication in ovaries, which leads to mtDNA deficiency in mature eggs. Targeting Larp to the mitochondrial outer membrane independently of MDI restores local protein synthesis and rescues the phenotypes of *mdi* mutant flies. Our work suggests that a selective translational boost by the MDI-Larp complex on the outer mitochondrial membrane might be essential for mtDNA replication and mitochondrial biogenesis during oogenesis.

D104 Signaling through the G-protein-coupled receptor Rickets is important for polarity, detachment, and migration of the border cells in *Drosophila*. *Lauren ANLLO*, Trudi Schüpbach. PRINCETON UNIVERSITY, PRINCETON, NJ.

Cell migration plays crucial roles during development. An excellent model to study coordinated cell movements is provided by the migration of border cell clusters within a developing *Drosophila* egg chamber. In a mutagenesis screen, we isolated two alleles of the gene *rickets* (*rk*) – encoding a G-protein-coupled receptor. The *rk* alleles result in border cell migration defects in a significant fraction of egg chambers. In *rk* mutants, border cells are properly specified and express the marker Slbo. Yet, analysis of both fixed as well as live samples revealed that some single border cells lag behind the main border cell cluster during migration, or, in other cases, the entire border cell cluster can remain tethered to the anterior epithelium as it migrates. These defects are observed significantly more often in mosaic border cell clusters, than in full mutant clusters. Reduction of the Rk ligand, Bursicon, in the border cell cluster also resulted in migration defects, strongly suggesting that Rk signaling is utilized for communication within the border cell cluster itself. The mutant border cell clusters show defects in localization of the adhesion protein E-cadherin, and apical polarity proteins during migration. E-cadherin mislocalization occurs in mosaic clusters, but not full mutant clusters, correlating well with the *rk* border cell migration phenotype. Our work has identified a receptor with a previously unknown role in border cell migration that appears to regulate detachment and polarity of the border cell cluster coordinating processes within the cells of the cluster themselves.

D105 A mutation in *fat2* uncouples tissue elongation from global tissue rotation in *Drosophila*. *F. Aurich*, C. Dahmann. Technische Universität Dresden, Dresden, Germany.

Global tissue rotation was proposed as a morphogenetic mechanism controlling tissue elongation. In *Drosophila* ovaries, global tissue rotation of egg chambers coincides with egg chamber elongation. Egg chamber rotation was put forward to result in circumferential alignment of actin filaments and extracellular fibers. These fibers serve as molecular corsets to restrain growth of egg chambers perpendicular to the anteroposterior axis, thereby leading to the preferential egg chamber elongation along this axis. The atypical cadherin Fat2 is required for egg chamber elongation, rotation, and the circumferential alignment of actin filaments and extracellular fibers. The localization of Fat2 protein at the basal side of follicle cells is planar polarized. Fat2 protein is enriched on cell junctions oriented parallel to the long axis of the egg chamber. The functional relationship between Fat2 planar polarized localization, egg chamber rotation and egg chamber elongation, however, remained unclear.

Here we have generated a truncated form of Fat2 that lacks its entire intracellular region. *fat2* mutant egg chambers expressing this truncated protein display normal actin and extracellular fiber alignment and properly elongate. However, the localization of the truncated Fat2

protein is not planar polarized and these egg chambers fail to rotate. Our data for the first time uncouple Fat2 planar polarization and global tissue rotation from egg chamber elongation. Thus global tissue rotation, even though coinciding with tissue elongation, is not a necessary prerequisite for elongation.

D106 Steroid signaling in mature follicles is essential for *Drosophila* ovulation. *E. Knapp*[1], J. Sun[1,2]. 1) Physiology and Neurobiology, University of Connecticut, Storrs, CT; 2) Institute for Systems Genomics, University of Connecticut, Storrs, CT.

Steroid hormones ecdysone (E) and 20-hydroxyecdysone (20E) are not only critical for early development in *Drosophila*, but are also essential in adult physiology. Particularly, ecdysteroid signaling has been shown to regulate female specific metabolic state and multiple processes of oogenesis, thus functionally equivalent to estrogenic steroids in mammals. Unlike estrogenic steroids, mainly progesterone, that are essential for ovulation, it is unknown whether ecdysteroid signaling regulates *Drosophila* ovulation. Our recent work demonstrated that Drosophila ovulation, resembling mammalian ovulation, involves the degradation of posterior follicle cells, the rupture of mature oocytes into the oviduct, and the formation of corpus luteum by the residual follicle cells. In addition, this rupture process is induced by the octopamine (OA) signaling in mature follicle cells that elicits an increase in intracellular calcium to activate matrix metalloproteinase 2 (Mmp2) enzymatic activity. In this study, we demonstrated that ecdysteroid signaling is operating in mature follicle cells to control ovulation. Knocking down shade (shd), encoding the enzyme for converting E to 20E, in mature follicle cells inhibits OA-induced follicle rupture *ex vivo* and ovulation *in vivo*. These defects can be rescued by ectopic expression of Shd or exogenous 20E. In addition, disruption of the ecdysone receptor (EcR) function in mature follicle cells also causes similar ovulation defects. Furthermore, we showed that ecdysteroid signaling functions upstream of calcium rise to regulate Mmp2 activity. Our data strongly suggest that 20E production in follicle cells prior to ovulation is necessary to prime mature follicles to be responsive to neuronal ovulatory stimuli, thus providing mechanistic insights into steroid signaling in ovulation and further evidence that ovulation control is largely conserved between fly and mammals.

D107 Identification and characterization of an "insect epididymis". *T. L. Karr*[1], M. Rosenow[2], L. Benner[3], B. Oliver[3], S. Skerget[4]. 1) Drosophila Genomics and Genetic Resources, Kyoto Institute of Technology, Kyoto, JP; 2) Caris Life Sciences, Phoenix, AZ; 3) National Institutes of Health, NiDDK, Bethesda, MD; 4) Arizona State University, Tempe, AZ.

Sperm development is accompanied by post-testicular modification of sperm as they transit the epididymis- a process necessary for fertilization competency. However, unlike well-studied mammalian systems, less is known about what, if any, similar sperm modifications occur in in other taxonomic groups, including Drosophila. However, recent work on the Dmel sperm proteome (DmSP, ~1100 proteins) revealed that ~50% of genes encoding the DmSP were not significantly expressed in the testis suggesting they were inserted following spermatogenesis. RNA-seq analysis confirmed that these genes were significantly expressed in the terminal epithelium and seminal vesicle (further termed "TE/SV" tissue). This raised the intriguing possibility that these proteins are inserted into sperm after exit from the testis. Analysis of the seminal vesicle proteome revealed functional enrichment in protein secretion, translocation and targeting similar to those found in secretory cells and polarized epithelia of the mammalian epididymis suggesting a similar function in the TE/SV. To further explore tissue-specific origin of the DmSP we identified a subset of genes not overexpressed in the testis (FA "down") but present in significant protein levels (determined by spectral counting). From this list, three readily available CPTI protein-trap lines of the DmSP were identified and their cell- and tissue-specific expression patterns were monitored by epifluorescence microscopy. As predicted, all three proteins showed low level testis expression and high expression in the seminal vesicle and the terminal epithelium suggesting that sperm exiting the testis were modified during transit into, or residence within, the TE/SV. Taken together these results suggest that Drosophila sperm are extensively modified following exit from the testis during transit into, and storage within, the seminal vesicle in a manner akin to that observed in the mammalian epididymis. As such, an "insect epididymis" could provide a rich new experimental model system useful for the study of fertility and related reproductive processes in both arthropods and vertebrates.

D108 An autonomous requirement of the lysosomal nuclease DNaseII in a caspase-independent primordial germ cell death in the *Drosophila* embryo. *L. Tarayrah*, E. Arama. The Weizmann Institute of Science, Rehovot, IL.

Programmed cell death (PCD) is an intracellular genetic program that is activated by all dying metazoan cells. Apoptosis is the most abundant form of PCD and is manifested by the activation of cysteine proteases called caspases. However, activation of caspases does not always lead to apoptosis and emerging evidence suggests the existence caspase-independent alternative cell death (ACD) pathways. Considering that cancer cells have developed ways to evade apoptotic cell death, uncovering the molecular mechanisms underlying ACD pathways has tremendous therapeutic value. However, progress in this field has been slow primarily due to the lack of physiological paradigms of ACD. In this study, we characterize the non-apoptotic cell death of primordial germ cells (PGCs) in the *Drosophila* embryo. During the early stages of embryo development, germ-line progenitors known as pole cells originate at the posterior pole and must migrate to their somatic partners in order to form the embryonic gonad. Prior studies have demonstrated the involvement of guidance cues that drive PGC migration, while mismigrating germ cells that remain ectopic to the gonad are eliminated. These findings suggest the existence of a mechanism within the embryo that regulates germ cell survival, however little is known about the molecular details governing this elimination mechanism. Our results indicate that PGCs that do no coalesce into a gonad by stage 13 of embryo development undergo caspase-independent cell death that involves the activity of lysosomes. We also find that DNaseII, a lysosomal deoxyribonuclease, is required maternally and cell autonomously in PGCs to drive their elimination providing an excellent physiological system to investigate a caspase-independent cell death pathway *in vivo.* .

D109 Move or Die: Linking caspases and cell migration and invasion in *Drosophila*. *E. Arama*, A. Gorelick, R. Weiss, A. Florentin, L. Tarayrah. Weizmann Institute of Science, Rehovot, IL.

The initiator caspase Dronc and the effector caspase Drice are required for most of the developmental and stress-induced apoptosis in *Drosophila*, whereas the role of the minor effector caspase, Dcp-1, is largely dispensable. After irradiation-induced apoptosis, both Drice and Dcp-1 become activated in wing imaginal discs (WDs). Here we show that following ionizing irradiation, WD cells compromised for caspase activity change their morphology, form protrusions, loose E-cadherin expression, delaminate and migrate away from their original compartment in an invasive manner. We termed this process irradiation-induced cell migration (ICM), and it is reminiscent of the epithelial-to-mesenchymal transition (EMT). Interestingly, we revealed both autonomous and non-autonomous factors required for ICM induction. We performed a candidate RNAi screen for signaling pathways involved in ICM induction. We then isolated the migrating cells and subjected them to RNA-seq analysis. Here I will describe our recent findings about the pathways and mechanisms underlying this unexpected phenomenon.

D110 Lysosome activity controls nurse cell death non-autonomously. *Albert Mondragon*, Alla Yalonetskaya, Anthony Ortega, Yuanhang Zhang, Kim McCall. Boston University, Boston, MA.

One of the most prevalent forms of cell death in the human body is phagoptosis, where one cell kills and engulfs another cell that would otherwise continue living. The mechanism of phagoptosis is poorly understood. We have recently shown that ovarian nurse cells die by this form of cell death, providing a powerful model for phagoptosis. In the Drosophila ovary, there are 15 nurse cells that support the oocyte throughout development. In late stages of oogenesis the nurse cells dump their cytoplasmic contents into the oocyte, and are subsequently acidified and cleared by the surrounding stretch follicle cells. We have previously found that the engulfment machinery (Draper, Ced-12, etc.) acts through the JNK pathway within the stretch follicle cells to promote nurse cell death, but the exact mechanism remained elusive. Through genetic manipulation and live imaging, we have determined that lysosomal components actively kill the nurse cells. To understand the role of lysosomes more precisely, we cultured late stage egg chambers and live-imaged nurse cells throughout death with probes and GFP fusion proteins. LysoTracker staining shows a gradual increase in nurse cell acidification and clearance by surrounding follicle cells. A candidate RNAi screen of genes encoding lysosomal proteins identified several key lysosomal components such as V-ATPases and cathepsins, which are required non-autonomously for the acidification and clearance of nurse cells. Additional hits from the RNAi screen are being followed up by confocal imaging and live imaging of GFP-tagged proteins. Altogether, this work further characterizes this novel form of cell death and illustrates the importance of non-autonomous control over cell death. Our work also demonstrates an essential role for lysosomal machinery in actively killing neighboring cells.

D111 Programmed necrosis control germ cell homeostasis during Drosophila spermatogenesis. *B. Mollereau*[1], S. Vincent[1], S. Yacobi-Sharon[2], B. Gibert[3], P. Mehlen[3], J. Felten[1], G. Chatelain[1], M. Decoville[4], V. Girard[1], E. Arama[2], F. Napoletano[1,5]. 1) Ecole Normale Supérieure de Lyon, LBMC, CNRS, INSERM, Lyon, France; 2) Weizmann Institute of Science, Rehovot, Israel; 3) Centre de Cancérologie de Lyon, INSERM, France; 4) CNRS, Orléans, France; 5) Department of Life Sciences, University of Trieste, Italy.

Regulated necrosis occurs in pathologies such as cerebral stroke and myocardial infarction, however the underlying mechanisms and its physiological relevance remain unclear. Here, we report a role for p53 in regulating necrosis in *Drosophila* spermatogenesis. We found that *Drosophila* p53 is required for the programmed necrosis that occurs spontaneously in mitotic germ cells during spermatogenesis. Prevention of p53-dependent necrosis resulted in testicular hyperplasia, which was reversed by restoring necrosis in spermatogonia. *Drosophila* spermatogenesis will thus be useful models to identify inducers of necrosis to treat cancers that are refractory to apoptosis.

D112 Regulation of cell size by variant cell cycles. *T. L. Orr-Weaver*[1,2], J. Von Stetina[1], L. E. Frawley[1,2], Y. Unhavaithaya[1]. 1) Whitehead Institute, Cambridge, MA; 2) Dept. of Biology, Massachusetts Institute of Technology, Cambridge, MA.

The endocycle is a modified cell cycle consisting of solely S and G phases that is widely used in differentiated Drosophila tissues. DNA replication in the absence of mitosis and cell division increases ploidy and cell size. We find that in addition to the endocycle an alternate cell cycle, endomitosis, is utilized in the subperineurial glia (SPG) in the Drosophila brain. In this variant cycle, mitosis and nuclear division occur, but not cytokinesis. Thus cell number does not increase, and large multinucleate cells are produced. The SPG are the first identified endomitotic cells in Drosophila. The presence of both endocycling and endomitotic SPG raises the question of the function of each of the two cell cycle types. We previously showed that increased cell size of the SPG is crucial for their role in maintaining the blood-brain barrier as the neuronal mass of the nervous system increases during development. Therefore we analyzed the developmental regulation of the endocycle and endomitosis, and the contribution of each to SPG size and the blood-brain barrier. We found that during embryogenesis initially all SPG enter the endocycle, but between the first and second larval instar stages the majority of SPG in the brain switch to endomitosis. Notch signaling is required for SPG to remain in the endocycle. To evaluate the functional roles of endomitosis and the endocycle, we reduced Notch signaling and consequently increased the proportion of SPG undergoing endomitosis. Additionally, we generated brains in which all SPG are endocycling by reducing expression of the Cdc25 phosphatase, String. Either of these changes in the ratio of endocycling to endomitotic cells caused defects in the blood-brain barrier. Thus the proper proportion of endocycling and endomitotic SPG is essential, likely to ensure total cell size of the SPG tissue layer to maintain an envelope over the neuronal mass, as we observe that cell size increases disproportionally to ploidy with increasing nuclear number.

D113 An inhibitory mono-ubiquitylation of the *Drosophila* initiator caspase Dronc functions in both apoptotic and non-apoptotic pathways. *HE Kamber*[1*], M. Ditzel[2], P. Meier[3], A. Bergmann[1]. 1) Department of Molecular, Cell and Cancer Biology, University of Massachusetts Medical School, Worcester, MA, 01605, USA; 2) MRC Institute for Genetics and Molecular Medicine, The University of Edinburgh, Edinburgh, UK; 3) The Breast Cancer Now Toby Robins Research Centre, Institute of Cancer Research, London SW3 6JB, UK.

Apoptosis is an evolutionary conserved cell death mechanism, which requires activation of initiator and effector caspases. The *Drosophila* initiator caspase Dronc, the ortholog of mammalian Caspase-2 and Caspase-9, has an N-terminal CARD domain that recruits Dronc into the apoptosome for activation. In addition to its role in apoptosis, Dronc also has non-apoptotic functions such as compensatory proliferation and male genitalia rotation. Given the detrimental effect of caspases, their activity is tightly controlled. One control mechanism is ubiquitylation. However, the mechanistic details of ubiquitylation of Dronc are less clear. For example, monomeric inactive Dronc is subject to non-degradative ubiquitylation in living cells, while ubiquitylation of active apoptosome-bound Dronc triggers its proteolytic degradation in apoptotic cells. Here, we examined the role of non-degradative ubiquitylation of Dronc in living cells *in vivo*, i.e. in the context of a multi-cellular organism. Our *in vivo* data suggest that in living cells Dronc is mono-ubiquitylated on Lys78 (K78) in its CARD domain. This ubiquitylation prevents activation of Dronc in the apoptosome and protects cells from apoptosis. Furthermore, K78 ubiquitylation plays an inhibitory role for non-apoptotic functions of Dronc. We provide evidence that not all of the non-apoptotic functions of Dronc require its catalytic activity. In conclusion, we demonstrate a mechanism whereby Dronc's apoptotic and non-apoptotic activities can be kept silenced in a non-degradative manner through a single ubiquitylation event in living cells.

D114 The *Drosophila* TNF Eiger activates Dronc-dependent necrosis when apoptosis is blocked. *M. Li*, Y. Fan. School of Biosciences, University of Birmingham, Birmingham, United Kingdom.

Eiger (Egr), the homolog of the mammalian tumor-necrosis factor (TNF), is the ligand of the c-Jun N-terminal kinase (JNK) stress response signaling pathway in *Drosophila*. Although expression of Egr frequently leads to apoptosis, it has also been implicated in activation of non-apoptotic cell death. For example, expression of Egr under the control of the eye-specific driver GMR (*GMR>egr*) results in a small eye phenotype which cannot be suppressed by P35, an inhibitor of the effector caspases DrICE and Dcp-1. Paradoxically, it has been reported that *GMR>egr*-induced eye ablation phenotype can be partially rescued by defective apoptosis through reduction of pro-apoptotic gene expression or inhibition of the initiator caspase Dronc. It is therefore not yet clear whether Egr can induce both apoptotic and non-apoptotic cell death, and if so, how such processes are coordinated. Here, we show that *GMR>egr* primarily induces apoptosis starting from the 3rd instar larval stage. Loss-of-function analysis reveals that such induction of apoptosis is through the canonical pathway and mainly mediated by the pro-apoptotic gene *hid*. Intriguingly, when apoptosis is blocked by expression of P35 (*GMR>egr, p35*), necrosis, indicated by Propidium Iodide labeling and Electron Microscopy, is induced that counteracts apoptotic inhibition by P35 resulting small eyes at the end. Moreover, loss one copy of Dronc, which does not affect *GMR>egr*-induced apoptosis, can suppress *GMR>egr, p35*-induced eye ablation phenotype suggesting different levels of Dronc are required for Egr-induced apoptosis and, if apoptosis is blocked, necrosis. As the mammalian TNF can activate the extrinsic apoptosis pathway and, if apoptosis is defective, triggers necrosis, our study suggests such a process is more conserved in *Drosophila* than previously thought.

D115 Enhancer of Polycomb represses transcription of Cyclin B during male germ cell differentiation. *L. Feng*, X. Chen. Johns Hopkins University, Baltimore, MD.

Adult stem cells modulate balance between proliferation, differentiation and cell death to maintain tissue homeostasis. We use *Drosophila* testes to study how germ cells transit from proliferation to differentiation, and repair DNA damage to prevent cell death. In testes, Cyclin B (CycB) accumulates in proliferating germ cells, decreases upon completion of mitosis, and regain expression just before meiotic G2/M transition. Transcriptional activation and translational repression of CycB in meiosis are well studied. But how CycB is downregulated after mitosis and if such downregulation is crucial remain unknown. Here we found chromatin factor E(Pc) transcriptionally represses CycB by modulating H4 acetylation and reduced CycB is essential for germ cell differentiation. Moreover, E(Pc) depletion causes accumulated DNA double strand breaks and severe germ cell death. In addition, lacking activity of Tip60 histone acetyltransferase (HAT) leads to similar defects. Taken together, acetylation plays crucial roles in maintaining tissue homeostasis though transcriptional regulation and DNA damage repair.

D116 Towards a Genetic Understanding of Behavior Evolution: An Ion-channel Gene Causes Natural Courtship Song Variation in *Drosophila*. *Yun Ding*[1], Augusto Berrocal[1,2], Tomoko Morita[1], Kit Longden[1], David Stern[1]. 1) Janelia Research Campus, HHMI, Ashburn, VA; 2) UC Berkeley, Berkeley, CA.

Animal species display enormous variation for innate behaviors, but little is known about how genomes evolve to generate this diversity. The features of ***Drosophila*** courtship song are easy to quantify and vary widely within and between species, making song an excellent system for genetic studies. We developed a mapping strategy that combined traditional mapping protocol with high-resolution recombinant mapping using engineered visible markers via CRISPR/Cas9 genome editing. This approach allowed us to map the sine song frequency difference between two wild isolates, ***Drosophila simulans 5*** and ***D. mauritiana 29***, to a 966 bp region within the ***slowpoke*** locus, which encodes a calcium-activated potassium channel. We confirmed that ***slowpoke*** is the causal locus using a reciprocal hemizygosity test, and further narrowed down the casual mutation to an intronic insertion of retrotransposon that occurred within ***D. simulans*** populations. Difference in exon usage was observed around the retrotranspon insertion site. Like many ion-channel genes, ***slowpoke*** is expressed widely in the nervous system and influences many behaviors. The ***slowpoke*** mutants sing very little song with disrupted features. However, the naturally evolved ***slowpoke*** alleles cause significant variation in only one component of courtship song, showing that a highly pleiotropic ion channel gene can

evolve to generate a specific new behavior pattern through changes in gene regulation. Currently, we are trying to confirm the retrotranspon insertion as the causal mutation by targeted deletion, and identify the molecular mechanism of how the retrotranspon insertion has fine-tuned the *slowpoke* function.

D117 A delicate balance of mating preference in *Drosophila melanogaster*. *Akihiko Yamamoto*[1,2], Michael Magwire[1,2,3], Lauren Dembeck[1,2,4], Mary Anna Carbone[1,2], Trudy Mackay[1,2]. 1) Biological Sciences, North Carolina State University, Raleigh, NC; 2) W M Keck Center for Behavioral Biology , North Carolina State University, Raleigh, NC; 3) Syngenta Biotechnology, Durham, NC; 4) Okinawa Institute of Science and Technology Graduate University, Okinawa, Japan.

Incipient speciation between stocks of Sub-Saharan Africa and cosmopolitan populations in *D. melanogaster* has been reported for decades but genes involved in their mating preference are elusive because prevalence of inversions in African populations hampers detailed genetic analyses. We employed a new strategy to explore the variations in a cosmopolitan population and confirmed 42 genes which affected significantly on the copulation success of cosmopolitan males to Zimbabwean Z30 females. Surprisingly, most of the RNAi mediated disruptions of these genes enhanced the male copulation success and a weak driver did so rather than the strong ones. Using mutants affecting female's sensory systems and surgical removal of female antennae, we demonstrated that the effects of gene-disruption on cosmopolitan males were perceived by *Ir8a*/*Ir25a* mediated olfaction. We further specified male oenocytes as the target of these genes and most of methyl branching cuticular hydrocarbons were reduced in the gene-disrupted males.

D118 Mechanism of hybrid incompatibility between two subspecies of *Drosophila pseudoobscura*. *C. Large*, N. Phadnis. University of Utah, Salt Lake City, UT.

Understanding the genetic and molecular basis of hybrid incompatibilities is a long-standing and central problem in evolutionary genetics. Despite decades of studies, we understand little about the genetic basis of hybrid sterility and even more lacking is our understanding of the molecular basis of hybrid dysfunction. The Bogota and USA subspecies of *Drosophila pseudoobscura* provides a paradigmatic case of the earliest stages of speciation. Previously, we have shown that a single gene, *Overdrive* (*Ovd*) is essential for both hybrid sterility and segregation distortion in hybrid F1 males between these populations. Little is known, however, about the normal function of *Ovd* within species and its molecular role in causing hybrid sterility between species.

To understand the molecular basis of hybrid sterility, we performed a comprehensive cytological characterization of spermatogenesis in *D. pseudoobscura* hybrid F1 males. Our results show that the primary defect in hybrid males is a failure to compact DNA after the last meiotic division. This failure to properly condense DNA leads to an arrest in sperm development later in spermiogenesis, leading to little to no functional sperm. We further employed CRISPR-Cas9 based methods to GFP tag *Ovd* at its native locus in *D. melanogaster*. Our studies on the localization patterns of *Ovd* in the developing male germline in congruence with the hybrid defect suggests that *Ovd* has a direct effect on chromatin state during spermatogenesis that leads to hybrid incompatibility between these new subspecies. Together, these findings are providing the first insights into the molecular function of *Ovd* and highlight the role of chromatin state dynamics in the evolution of reproductive barriers between species.

D119 Recurrent changes to *pdm3* drive convergent evolution of female-limited polymorphism in the *Drosophila montium* subgroup. *Emily K. Delaney*[1], Amir Yassin[2], Adam Reddiex[3], Héloïse Bastide[2], Thaddeus Seher[1], Nicholas Appleton[3], Justin Lack[2], Jean R. David[4], Stephen F. Chenoweth[3], John E. Pool[2], Artyom Kopp[1]. 1) University of California-Davis, Davis, CA; 2) University of Wisconsin-Madison, Madison, WI; 3) University of Queensland, St. Lucia, Australia; 4) Université Paris Sud, Gif-sur-Yvette, France.

In spite of a shared genome, males and females can have dramatically different phenotypic traits. Some sex-specific traits are also polymorphic, so that different genotypes are expressed as two or more phenotypes in one sex but not the other. Such sex-limited polymorphisms offer an opportunity to reconstruct the origin of molecular mechanisms limiting trait expression to a single sex. The *Drosophila montium* subgroup, comprised of 76 species, harbors diverse abdominal pigmentation: some species are sexually monomorphic, others are dimorphic, and many species have female-limited color dimorphism (FLCD), where females are either light or dark but males are always the same color. Thus, sexually dimorphic and sexually monomorphic genotypes can either segregate within a single species or be fixed between closely related species, making this group an ideal model for reconstructing evolutionary transitions between sex-specific and sexually monomorphic development. We mapped FLCD in four distantly related species from the *Drosophila montium* subgroup and found that it mapped to the same locus, the POU domain transcription factor (*pdm3*), in all cases. In *D. serrata*, we pinpointed a small region within the first intron of *pdm3* that differs in size and sequence between color morphs. The dark allele contains putative binding sites for *dsx,* the transcriptional effector of the *Drosophila* sex determination pathway, and the HOX gene *Abd-B,* which controls the development of posterior abdominal segments. The region spanning this complex structural variant acts as an abdominal enhancer in transgenic reporter assays, suggesting that sex-limited polymorphism is due to intraspecific segregation of *cis*-regulatory variation in *pdm3*. In *D. kikkawai, D. leontia,* and *D. burlai*, the structural polymorphism observed in *D. serrata* is not present, and female pigmentation is associated with different non-coding variants upstream of *pdm3*. These results suggest that FLCD has originated multiple times through regulatory changes in the same locus.

D120 Evolution of the Sex Peptide Network: Lineage-specific adaptive evolution and gene duplication. *Meaghan McGeary*, Geoffrey Findlay. College of the Holy Cross, Worcester, MA.

The sex peptide (SP) network consists of at least 13 proteins from males and females that interact to control female behavior and physiology after mating. In *Drosophila melanogaster*, these changes can last for several days and include increased egg production, efficient sperm storage, and a decrease in female receptivity to remating. However, other *Drosophila* species show dramatically different reproductive phenotypes, including faster female remating and differences in sperm size and sperm storage patterns. We thus investigated the molecular evolution of the SP network proteins across the *Drosophila* genus. After bioinformatically identifying SP network proteins in up to 22 species, we used PAML to test whether any proteins had sites that had evolved under recurrent positive selection and to test for adaptive evolution on specific phylogenetic branches that correlate with major changes in reproductive phenotypes. While only 2 of 11 tested genes showed evidence of recurrent positive selection across the phylogeny, we identified bursts of adaptive evolution on lineages correlating with phenotypic changes. For example, the lineage leading to the melanogaster species group showed evidence of adaptive evolution on three genes. This lineage corresponds to a change in the expression level of the SP receptor in the female reproductive tract and to two gene duplication events of the network member, seminase. We then investigated the importance of gene duplication in the network's evolution by studying seminase in further detail. Three copies of this gene are present in the melanogaster group of *Drosophila*, while only a single copy is found in other species. PAML analysis showed no evidence for adaptive evolution of seminase following duplication, and gene expression analysis in seven species showed that seminase and both paralogs are expressed specifically in males. Taken together, these results paint a dynamic picture of SP network evolution, with different lineages and genes having experienced different selective pressures.

D121 Investigating the female's role in sperm competition in *Drosophila melanogaster*. *S. White*, J. Sitnik, C. Chow, A. Clark, M. Wolfner. Cornell University, Ithaca, NY.

The formation of a fertilized egg involves many interactions between males, females, and their gametes. This is even more complex in cases of multiple mating, as in *Drosophila melanogaster,* as the presence of ejaculates from multiple males presents the opportunity for sperm competition to occur. Male-derived seminal fluid proteins are known to influence sperm competition outcomes, in addition to other post-mating effects. While studies have shown that female genotype is also important for sperm competition outcome, the mechanisms underlying the female's contribution to the success of a particular male's sperm are less understood.

A previous GWAS screen based on sperm competition phenotypes across natural isolates of *D. melanogaster* identified candidate genes for the female's contribution to sperm competition. Interestingly, about half of the top 33 genes have predicted neurological function, pointing to an active role for the female in sperm use and preference. We performed ubiquitous or tissue-targeted local RNAi knockdowns to assess the impact of decreased expression of these genes on sperm competition. Females were scored for sperm competition effects using progeny-phenotype assays, and for reproductive processes including fecundity, fertility, and resistance to remating. Of 29 genes tested, knockdown of 9 affected sperm competition outcomes. Genes whose knockdowns in females affect sperm competition outcomes will be further characterized for their effects on sperm storage, retention and release, and on sperm competition, by direct examination of sperm dynamics within the female, for the neurons (or other tissues) through which these genes exert their effects, and for the roles of the specific alleles found in the wild-derived genomes. Collectively, results from these experiments will provide a clearer picture as to how females are influencing sperm competition outcomes.

We thank the NIH for funding (R01-HD059060) and HHMI for a Gilliam Fellowship to SLW.

D122 Missing variation revealed by deep sequencing of individuals in a population of *D. simulans*. *S. A. Signor*[1], Felicia New[2], Lauren McIntyre[2], Sergey Nuzhdin[1]. 1) University of Southern California, Los Angeles, CA; 2) University of Florida, Gainesville , FL.

The observed heritable variation in complex phenotypes can only partially be explained by mutation-selection balance. Directional selection is expected to remove most additive variation, so possible hypotheses for its maintenance include balancing selection, inefficient selection, or failure of populations to reach equilibrium . Looking at patterns of polymorphisms to corroborate these hypotheses mostly negative values of Tajima's D have been observed in *Drosophila* (indicating selective sweeps or rapid population expansion). Here, we have established a panel of 170 nearly homozygous *D. simulans* genotypes from a single stable population and found that D is strongly biased towards positive values in the regions of normal recombination. We rule out demography, admixture, and balancing selection based on the patterns of linkage disequilibrium and Tajima's D. Using recently developed statistical tests based on a measure of haplotype homozygosity (H12) we were able to detect numerous soft and hard sweeps and distinguish between them (H2/H1). We found evidence for abundant incomplete soft sweeps, including that they are much more numerous than in comparable populations of *D. melanogaster*. We hypothesize that transient selective sweeps might be responsible for the bulk of phenotypic variation in complex traits. This is a potential explanation for the excess of variation observed in most traits compared to theoretical expectations.

D123 Mutational patterns in Drosophila melanogaster. *Zoe June Assaf*, Dmitri Petrov. Stanford University, Stanford, CA.

It is critical to have accurate estimates of mutational rates and biases in order to successfully perform many population genetic analyses. Yet, because a substantial fraction of new mutations are deleterious, our ability to detect de novo events is severely limited. Fortunately, the scientific community studying Drosophila melanogaster has generated a large body of sequence data that is publicly available. We leverage these resources, in combination with additional strains sequenced in our lab, to investigate mutational patterns in Drosophila melanogaster using two different strategies.

The first strategy is via mutational accumulation, an experiment that allows new mutations to accrue in the genomes of laboratory strains,

and which has now been conducted three independent times. The two previously published experiments used the inbreeding method of mutation accumulation (Keightley et. al. 2009, Schrider et. al. 2013) and to this we are contributing a novel data set that was generated using an alternative experimental method, one which additionally permits recessive strongly deleterious mutations to accumulate. We find a significantly higher mutation rate than previously reported, suggesting that strongly deleterious recessive mutations are an important part of the mutational spectrum. In other metrics the three experiments have very similar patterns, and thus we merge these three resources and give estimates for a variety of fundamental mutational biases.

Mutation accumulation studies are excellent for measuring mutation rates, yet our ability to characterize other more subtle mutational patterns is still limited by the small number of events which occur during these experiments. To address this, we combine the individually sequenced strains made available by the Drosophila Genome Nexus (which includes lines from DGRP, DPGP, and DSPR) (Lack et. al. 2015), with newly generated sequence data using pooled individuals from natural populations, which collectively represent >17,000X coverage of >5,000 strains. These data sets allow the detection of extremely rare polymorphisms, which we further validated with resequencing. Extremely rare variants are a class of sites enriched for new deleterious mutations, because at low frequencies their dynamics are dominated by stochastic rather than selective forces. We show that the these extremely rare variants in fact approach the de novo spectrum as revealed by mutation accumulation experiments, and use this high quality set of rare variants to measure additional mutational patterns.

D124 Cell fate transformations in sine oculis eye-specific LOF mutants obscures direct regulatory interactions within the retinal determination network. *B. Weasner*, J. Kumar. Indiana University, Bloomington, IN.

The *sine oculis* (*so*) and *eyes absent* (*eya*) genes are required for retinal development as mutations in either gene leads to the complete absence of the adult retina. These proteins are known to form a biochemical complex which functions as a bipartite transcription factor to activate targets necessary for eye development. Examination of null clones of either gene shows a corresponding absence of the partner protein. Together these data support a model in which *so* and *eya* regulate each other's expression. The no-eye phenotype that characterizes the eya^2 mutant is caused by the deletion of an eye specific enhancer element. Prior studies have concluded that this enhancer is the main cis-regulatory element controlling the expression of *eya* during eye specification. The enhancer contains a So binding site thus *eya* expression could be initiated and maintained by the So-Eya complex itself. Several additional So binding sites are present within the locus and a recent ChIP-seq study indicated the presence of several So peaks. We sought to identify additional cis-regulatory elements that might be responsive to the So-Eya complex but whose activity might be masked in the eya^2 mutant. To this end we expressed a SoVP16 chimeric molecule in eya^2 mutants and found it capable of restoring some Eya protein and partially rescuing the no-eye phenotype implying the presence of additional So responsive enhancers. We have identified multiple new cis-regulatory elements that are responsible for robust eya expression in the retina. Surprisingly, these elements are still activated in *so* mutants suggesting they are not regulated by So. This led us to more thoroughly examine Eya expression in *so* mutants. We find that the loss of Eya protein corresponds to the temporal de-repression of non-ocular genes within the eye field. We have previously shown that this de-repression ultimately results in a cell fate switch from retinal progenitor to head epidermis. Concurrently, a wave of cell death in the eye field clears retinal progenitors which, for reasons unknown, are incapable of undergoing the cell fate transformation. These two events lead to a progressive loss of Eya protein. Our examination of *so* mutant clones indicates that those lacking Eya protein expression ultimately differentiate into head capsule. As expected those clones which have not undergone a cell fate switch still contain Eya protein further supporting our model that *so* is not directly regulating *eya* expression in the developing retina. Finally, our data suggests that caution should be exhibited when using RD mutants to interpret regulatory interactions among RD network members as cell fate transformations can lead to false positive interactions.

D125 Genome-wide analyses of Hox target genes in *Drosophila melanogaster*. *N. P. Singh*[1], Bony De Kumar[1], Cyber Cynthia[1], Alexander Stark[2], Julia Zeitlinger[1], Kausik Si[1], Robb Krumlauf[1]. 1) Stowers institute for Medical research, Kansas City, MO; 2) Research Institute of Molecular Pathology, Vienna, Austria.

Hox genes regulate the antero-posterior (AP) body axis in all Bilaterians. Hox genes encode transcription factors which regulate expression of downstream target genes important for morphogenesis during early development. While the conserved role of these proteins is well established little is known about the nature of the downstream targets of Hox genes. Another challenge is that Hox proteins have very similar protein sequences, which makes it difficult to understand the basis for their individual specificities and functional activities. Studies in our group using epitope-tagged versions of Hox proteins and programmed differentiation of mouse ES cells have enabled us to examine binding regions and downstream targets of mammalian Hox proteins on a genome wide basis through ChIP-seq approaches. This work has uncovered both novel and overlapping sets of downstream target genes for Hox proteins. Computational analyses of these mammalian Hox binding sites and co-associated binding motifs is also helping to uncover roles for partners (factors and complexes) and co-factors that may serve to potentiate the activity and regulatory roles of the Hox proteins. The function of Hox genes in AP patterning is conserved from arthropods to humans. Hence, my research objective has been to compare and contrast genome wide binding properties of mouse and *Drosophila* Hox proteins to understand the general principles and molecular mechanisms underlying Hox protein binding at target loci. Towards this goal, I used specific antibodies against Drosophila Hox proteins and a fly stock having an epitope tagged version of Ubx. Using ChIP-seq and ChIP-nexus I have mapped the downstream targets of Antp, Ubx, Abd-A and Abd-B in fly genome in 4-16 hr embryos. Analysis of the target genes is revealing distinct subsets of common and different target regions. Based on finding in our mammalian Hox studies, we have also generated specific antibodies against the Drosophila REST protein (Charltan-Chn) and Mediator complex subunit Med19and mapped their downstream target genes. Our initial results suggest that Mediator, REST and Hox proteins share a large number of common targets in *Drosophila* genome. Genetic and biochemical experiments further indicate genetic and physical interactions between Hox, Chn and Mediator complexes. This data

implies that regulation of Hox target genes may involve input from Chn/REST and Mediator complexs in both *Drosophila* and mammals. We are now doing locus specific experiments to validate and understand more precisely the mechanisms of these interactions in gene regulation.

D126 Manipulating fate with light – an optogenetics tool to understand Bcd function. *A. Huang*[1], C. Amourda[1], T. E. Saunders[1,2,3]. 1) Mechanobiology Institute, Singapore; 2) Department of Biological Sciences, NUS, Singapore; 3) IMCB, A-star, Singapore.

At the onset of embryogenesis, the segmentation gene network translates maternal inputs into more complex body patterns. Quantitative studies using *Drosophila melanogaster* embryo as a model have characterized the temporal evolution of the maternal Bicoid (Bcd) gradient as well as downstream hierarchical genes. Nevertheless, how individual cells interpret a dynamic Bcd gradient at different time windows remains elusive. To better understand the temporal readout of Bcd, we developed an optogenetics tool to turn off Bcd transcription activity with blue-light (488nm) illumination while the activity is restored minutes after switching back to dark. We used the *hunchback* (hb)-MS2 reporter assay to confirm that 488nm illumination immediately abolishes the Bcd-dependent transcription of Hb in the anterior region of the embryo while leaving the posterior Bcd-independent domain intact. By inactivating Bcd activity at different time-windows during the blastoderm stage, we found that Bcd activity during both nuclear cycle (NC) 14 and NC 13 is essential for embryonic viability. Interestingly, although inactivation of Bcd during NC10-12 does not cause embryonic lethality, it results in an anterior shift of the downstream gap genes and pair-rule genes, resembling that of 1-copy Bcd embryos. This suggests that, at early stages, Bcd may be playing a role in presetting the competency of the nuclei to interpret Bcd in the later stages potentially by occupying DNA binding sites and/or remodeling the chromosomal conformation. Furthermore, we analyzed the cuticle patterns of embryos exposed to different time windows of Bcd-inactivation. Even during fast phase of cellularization Bcd inactivation results in embryo lethality, due to subtle defects at the most anterior region (e.g. mouth hook, cirri). Prolonged inactivation of Bcd (throughout cellularization or even earlier) impedes the formation of more posterior structures. This suggests that the more anterior in space the structure is, the later in time cell fate is determined. Last, by combining our optogenetics tool with light-sheet microscopy imaging, we were able to inactivate Bcd activity in only one lateral half of the embryo. We observed that the cephalic furrow formation was blocked at the illuminated side of the embryo, while the tissue invagination occurs normally in the non-illuminated side. As the mechanism of cephalic furrow formation has yet to be understood, our approach has the potential to elucidate the property of this morphological movement and identify essential molecular players. Our future work will focus on understanding the link between the initial Bcd-dependent cell fate determinations and morphogenesis during later embryonic development.

D127 Regulation of Dpp signaling by O-linked glycosylation. *M. J. Moulton*[1], G. B. Humphreys[2], A. Letsou[1]. 1) University of Utah, Salt Lake City, UT; 2) Pennsylvania State University, University Park, PA.

Animal embryogenesis requires input from diverse signaling pathways to coordinate proper placement and organization of body structures, tissues, and organs. Activation and deactivation of signaling pathways at the right time and place is essential for embryogenesis, with defects in signaling often leading to inborn errors of development. A molecular and biochemical understanding of signal transduction pathways is important for proper diagnosis and treatment of congenital developmental abnormalities. Our lab uses the fruit fly, *Drosophila melanogaster*, to understand developmental defects caused by alterations in Decapentaplegic (Dpp) signaling. Dpp is a homologue of vertebrate BMP2/4 and is a member of the TGF-β family of cytokines. In the fly, both losses and gains of Dpp signaling result in embryonic lethality with associated defects in dorso-ventral patterns and structures.

While we have previously reported that loss of the *mummy* (*mmy*)-encoded UDP-*N*-acetylglucosamine diphosphorylase results in ectopic Dpp signaling and embryonic lethality, here we provide mechanistic insight into the specific role of GlcNAc in Dpp signal antagonism. Our studies have their foundation in our discovery of *super sex combs* (*sxc*), the Drosophila O-GlcNAc transferase, in an RNAi screen for glycosyltransferases that share loss-of-function phenotypes with *mmy*. Here we show that, like Mmy, Sxc is a Dpp signaling antagonist that functions to restrict Dpp signal transduction in the *Drosophila* embryonic epidermis. Loss of *sxc* results in ectopic Dpp phenotypes, including an expanded pMad domain and a loss of larval ventral denticle belts. Notably, these markers of ectopic Dpp signaling persist in the absence of the Dpp Type I receptor Thickveins (Tkv), but require Saxophone (Sax). Taken together, our data point to Sax as a potent Dpp signal transducer in the embryonic epidermis, with the capacity to activate Mad well beyond the domain normally specified by Tkv. We speculate that epidermal Tkv and Sax function as short- and long-range signaling receptors, respectively, and that Sxc-mediated inhibition of Sax limits epidermal Dpp signaling to Tkv. Our studies are the first to: 1) demonstrate a role for Sxc in embryogenesis, and 2) provide mechanistic insight into the role of GlcNAc in modulating responses to Dpp.

D128 A Transcription Factor code controlling serial specification of muscle identities in *Drosophila* . *A. J. M. Vincent*, Laurence Dubois, Jean-Louis Frendo, Hélène Chanut-Delalande, Michèle Crozatier. CNRS/University Toulouse 3, Toulouse, FR.

Each Drosophila body wall muscle is seeded by one Founder Cell (FC) issued from division of a Progenitor Cell (PC). Each PC is selected from an equivalence group of myoblasts, called promuscular cluster (PMC), at a precise position within the somatic mesoderm. Muscle identity – i.e, orientation, size, shape and final skeletal attachment sites - reflects the expression by each PC and FC of a specific combination of identity Transcription Factors (iTFs). Our previous observation of the serial emergence of several PCs at the same position raised the question of how developmental time controlled the muscle iTF code. Through a systematic chromosomal deficiency screen, and focusing on the 6 dorso-lateral muscles, all issued from the same PMC, we identified new roles of Anterior Open (Aop), ETS domain lacking (Edl), Eyes absent (Eya), No Ocelli (Noc), and Sine oculis (So), in serial specification of muscle identities. The muscle phenotypes and windows of transcription of these, and several other transcription factors such as *collier/knot* (*col/kn*), and *slouch/S59*, in wild type and mutant embryos, as determined by using intronic probes, revealed a cascade of regulations integrating temporal with positional information. This includes lineage-specific feed-forward

or incoherent loops, and sequential use of alternative transcription start sites. Together, our data provide a dynamic view of the transcriptional control of muscle identity in *Drosophila* and an extended framework for studying interactions between general myogenic factors such as Nautilus/Myo-D and iTFs in evolutionary diversification of body wall muscles.

D129 Tracking morphogens down: Uncovering the Dpp morphogen gradient. *P. Sánchez Bosch*[1], R. Yagi[2], K. Basler[1]. 1) University of Zurich, Zurich, CH; 2) ETH Zurich, Zurich, CH.

Morphogens are secreted proteins that regulate key processes during development, such as cell proliferation, growth and patterning. They are produced from a localized source and somehow establish a concentration gradient. Decapentaplegic (Dpp), the *Drosophila* BMP, is expressed at the anterior-posterior (AP) boundary of the wing imaginal disc, generating an AP morphogenetic gradient that regulates the expression of key genes involved in the wing development. Despite the broad knowledge regarding its function, the mechanism by which the Dpp gradient is established and how it synchronizes proliferation and patterning has been under debate for years.

In order to analyze the behavior of Dpp and its effects in development, we have modified the endogenous *dpp* locus by CRISPR/Cas9, replacing the first coding exon by a transgenic dpp tandem. This gene tandem can be manipulated via FLP/FRT recombination. With the help of this system, we studied the behavior of the Dpp gradient, tracking the intracellular and extracellular Dpp populations.

We have imaged and measured Dpp gradient formation, protein degradation and other parameters involved in the movement of Dpp, in an effort to model the gradient dynamics. Our results show a fast protein turnover in the producing cells, as well as a high retention of the extracellular Dpp population. Our current data suggest that the gradient is generated by restricted Dpp diffusion and oppose to a free diffusion model, where fast protein degradation is required.

D130 Flies have 11 abdominal segments (as suggested by the bithorax complex). *Welcome Bender*[1], Sarah Bowman[2], Heber Domingues[1], Robert Kingston[2]. 1) Harvard Medical Sch, Boston, MA; 2) Mass. Genereal Hospital, Boston, MA.

Drosophila larvae have 8 obvious abdominal segments, and rudiments of the 9th and 10th abdominal segments have been described, based on ENGRAILED expression patterns in early embryos. The bithorax complex has a series of regulatory domains, one for each parasegment, from PS5 (~3rd thoracic segment) through the posterior abdominal segments. The domains were first described by E. B. Lewis, based on mapping of mutations affecting different segments. These domains have been confirmed by enhancer trap expression patterns, by parasegment-specific discontinuities in H3K27 methylation patterns, and by the coincidence of most domain borders with binding sites for CTCF. We have used CRISPR-mediated gene conversion to introduce a Gal4 reporter into putative parasegmental domains towards the distal end of the bithorax complex. We see distinctive expression patterns, especially in the CNS, corresponding to domains for PS12-16 (~7th through 11th abdominal segments). We are currently working to isolate nuclei from each of these parasegments, in order to confirm these domains with H3K27me3 maps.

D131 Spatial patterning of the *Drosophila* ventral epithelium is important for proper tissue shape. *Natalie Heer*, Adam Martin. MIT, Cambridge, MA.

During development two-dimensional epithelial sheets fold into three-dimensional structures. In many cases, such as the vertebrate neural tube and *Drosophila* gastrulation, epithelial cells constrict their apical surfaces, which coupled with a lack of constriction, or even expansion, of the basal domain is thought to cause epithelial folding. In *Drosophila* gastrulation, the ventral epithelium, or presumptive mesoderm, folds in response to the expression of two embryonic transcription factors, Twist and Snail. Here, we use quantitative microscopy to measure the pattern of gene activation, signaling, myosin activation, and cell shape in the ventral mesoderm. We used *in situ* hybridization to measure the distribution of Twist mRNA before and during tissue invagination. Next, we measured downstream signaling components, including T48 and DRhoGEF2, using fluorescent fusion proteins under the control of the endogenous promoters. In addition, we have measured the kinetics of non-muscle myosin II accumulation per cell along the dorsal-ventral axis within the ventral region. We have identified multiple mutations in the pathway downstream of Twist that lead to phenotypically similar defects in furrow morphology, some of which prevent invagination. We are testing whether these mutants disrupt the normal spatial pattern of contractility across the ventral mesoderm.

D132 An actomyosin-Arf-GEF negative feedback loop for tissue plasticity. *J.John. West*[1], T. Zulueta-Coarasa[1], R. Fernandez-Gonzalez[1,2], T. J. C. Harris[1]. 1) University of Toronto, Toronto, Ontario, CA; 2) The Hospital for Sick Children, Toronto, Ontario, CA.

Actomyosin contractility is critical for organizing various forms of morphogenesis. In some cases, high levels of contractility are important for driving cell shape changes, while in other cases, contractility must be maintained at moderate levels that help guide morphogenetic processes. The mechanisms that induce contractility are well characterized, however, it is not clear how actomyosin networks are counteracted to maintain moderate levels of contractility. Recently, the Arf-GEF Steppke was shown to antagonize actomyosin contractility during cleavage of the early *Drosophila* embryo. Therefore, we hypothesized that Steppke plays a similar role during later stages of embryogenesis as the ectoderm undergoes various forms of actomyosin driven morphogenesis. We report that Steppke is enriched in areas of high actomyosin contractility throughout embryonic development, including cytokinetic rings and adherens junctions. *step* zygotic mutant embryos fail head involution, and display a disorganized epithelium beginning at germ band retraction. In contrast to the wildtype tissue in which cells become elongated and aligned along the dorsal-ventral axis. Expression of a Steppke construct can rescue these defects, and its GEF activity is required for normal tissue structure. *step* mutants display abnormal local increases of actin and myosin levels, as well as increased tissue tension in the ectoderm. Thus, Steppke seems to act locally to antagonize actomyosin activity to promote the orderly spreading of an epithelial sheet. Strikingly, actomyosin activity appears responsible for locally recruiting Step since loss or gain of actomyosin function results in decreased or

increased Steppke levels respectively. Taken together, these data suggest a negative feedback loop in which Step is recruited to areas of high actomyosin activity, and antagonizes this activity for tissue plasticity.

D133 E-Cadherin decrease transmits proliferative-dependent forces via actin-myosin flows. *D. Pinheiro*[1,2], E. Hannezo[3], S. Herstzerg[1,2,4], I. Gaugue[1,2], M. Balakeriva[1,2], Z. Wang[1,2], S. Rigaud[1,2], O. Markova[1,2], Y. Bellaiche[1,2]. 1) Institut Curie, Paris, FR; 2) Sorbonne Universités, UPMC, France, Fr; 3) Cavendish Laboratory, Department of Physics, Cambridge, UK; 4) The Francis Crick Institute, Mill Hill Laboratory, London, UK.

During epithelial cytokinesis, the remodelling of adhesive cell-cell contacts between the dividing cell and its neighbours has profound roles in the integrity, arrangement and morphogenesis of proliferative tissues. This remodelling is powered by an interplay between contractile ring cosntriction in the dividing cell and the dynamics of non-muscle Myosin II (MyoII) in the interphasic neighbouring cells. Here we explore how the dividing cell regulates MyoII dynamics in its neighbours. We found that pulling forces, resulting from contractile ring constriction, lead to MyoII accumulation in the neighbouring cells independently of the classical Vinculin-mediated mechano-transduction pathway. We established that the contractile ring pulling forces promote local junction elongation, resulting in a decrease of E-Cadherin concentration at the ingressing ***adherens*** junction (AJ). In turn, the local reduction of E-Cadherin concentration and the contractility of the neighbouring cells promote a self-organized outward flow of F-Actin and MyoII, ultimately leading to their accumulation at the base of the ingressing AJ. Mechano-sensing has been extensively studied in the context of AJ strengthening to stabilize adhesive cell-cell contacts, we propose an additional mechano-sensing mechanism able to coordinate actin-myosin dynamics between epithelial cells and to sustain AJ remodelling in response to mechanical force.

D134 A gradient of Rac activity determines protrusion form and position in a 3-dimensional epithelial sheet. *M. Georgiou*, A. Couto, N. Mack, L. Favia. University of Nottingham, Nottingham, Nottinghamshire, GB.

Epithelial sheets exhibit several defining characteristics, including mechanically strong cell-cell junctions and a coordinated cell polarity, which maintain epithelial integrity and impart correct cell shape and tissue organization. Key to the acquisition of these characteristics is the intimate interplay between cell-cell adhesion, polarity proteins and regulators of the actin cytoskeleton.

By combining genetic and cell biological analyses we show that epithelial cells within the fly dorsal thorax possess distinct classes of dynamic protrusion along their apical-basal axis. Cells possess apical microvilli, lateral sheet-like protrusions at an intermediate level, and filopodia and lamellipodia at the base of the cell. Using in vivo inducible constructs that can sense or modify Rac activity, we demonstrate an apicobasal gradient of Rac activity that is required to correctly form and position these distinct classes of protrusion along the apicobasal axis of the cell. Apicobasal polarity is required to form this gradient, and we show that we can modify the Rac activity gradient in genetic mutants for specific polarity proteins, with consequent changes in protrusion form and position. We additionally show, using photo-activatable Rac constructs, that it is the level of Rac activity that determines protrusion form, with high levels of Rac activity required to form filopodia and lower levels required to form lamellipodia. Following exposure to pulses of laser light, thereby increasing Rac activity in photo-activatable-Rac expressing cells, we are able to convert lamellipodial protrusions to filopodial protrusions in the living animal.

It has long been known that polarity proteins are essential in maintaining epithelial cell shape, with loss of apicobasal polarity being a prerequisite for epithelial-to-mesenchymal transitions, and abnormal cell invasiveness. Our data provide a mechanism by which polarity proteins can influence Rac activity and the actin cytoskeleton, thereby ensuring the maintenance of epithelial cell shape, and consequently the architecture of the epithelium as a whole.

D135 A STRIPAK-like complex regulates axonal transport of autophagosomes and dense core vesicles by modulating PP2A activity. *A. L. Neisch*, T. P. Neufeld, T. S. Hays. University of Minnesota, Minneapolis, MN.

Axonal transport is essential for neuronal function and survival, and dysregulation of this transport is associated with neurodegenerative disorders. Axonal transport is precisely regulated by adaptor and scaffolding protein complexes that mediate the linkage and transport of cargoes by kinesin and dynein motor proteins. In an RNAi screen for autophagosome transport defects we identified Connector of kinase to AP-1 (CKA), a scaffolding protein with a previously uncharacterized role in axonal transport. CKA is a regulatory subunit of the phosphatase PP2A and a scaffolding protein for the Striatin-interacting phosphatase and kinase (STRIPAK) complex. We find that CKA, together with the core STRIPAK components Mob4 and Strip, regulates retrograde axonal transport of autophagosomes and dense cores vesicles. Additionally we show that CKA is in a complex with dynein, suggesting that a STRIPAK-like complex may regulate dynein activity. Our results reveal that CKA also interacts directly with the autophagosomal membrane protein Atg8, potentially providing a linkage between dynein and its autophagosome cargo. Furthermore, we show that CKA's ability to bind and regulate PP2A is required for dense core vesicle transport. Decreased PP2A activity is linked to neurodegenerative disease, and we find that dysregulation of PP2A activity by CKA disrupts axonal transport, which may contribute to disease progression. These findings demonstrate that a STRIPAK-like complex functions to regulate the transport of a subset of organelles important for both protein turnover and neuronal signaling, two processes essential for neuronal survival.

D136 Centrosomal proteins are required for autophagy to maintain neural homeostasis. *Y. Zheng*, O. Cabrera, J. Chen, B. Dietrick, R. Buchwalter, L. Kao, T. Megraw. Florida State University, Tallahassee, FL.

The centrosome is the major microtubule-organizing center in animals. Mutations in centrosomal genes cause primary microcephaly (MCPH), a neurological disorder characterized by smaller brain size due to insufficient neurogenesis, highlighting the importance of centrosome proteins in neural development and in maintaining neural health. Yet the etiological basis for MCPH and the role of centrosome proteins in its pathogenesis remains unclear. To explore the etiological basis of MCPH, we performed 2-D difference gel electrophoresis in combination with mass spectrometry to identify molecular signatures of MCPH mutant brains in Drosophila. Proteomic analysis led us to discover a novel role of

centrosomal proteins-regulation of autophagy. Autophagy is a major means by which cells clear misfolded or aggregated proteins and damaged organelles that contribute to the decline of neuronal health. We show that mutations in two essential centrosome proteins in Drosophila, *centrosomin (cnn)* and *sas-4*, impair starvation-induced autophagy and accumulate dramatically more protein aggregates. Consistently, *cnn* mutant larvae and flies are much more sensitive to starvation and have poor locomotor function compared to wild-type. Transmission electron microscopy analysis showed that Cnn regulates early steps in the assembly of autophagosomes, the double membrane structures that deliver cargos for lysosomal degradation. Mechanistically, our preliminary data showed that Cnn could act through a novel partner protein, an E3 ubiquitin ligase, to regulate autophagy. Overexpression of this E3 ligase induces autophagy, reduces cell size and causes tissue degeneration dependent on its E3 ligase activity. These findings reveal a novel role of centrosomal proteins and implicate defective autophagy as a novel function for centrosome proteins and a novel etiological basis for MCPH.

D137 Centrosome-pole cohesion requires Abnormal Spindle and Calmodulin to ensure proper centrosome inheritance in neural stem cells but is dispensable for brain size. *T. Schoborg*, A. Zajac, C. Fagerstrom, R. X. Guillen, N. M. Rusan. Naitonal Heart, Lung and Blood Institute, National Institutes of Health, Bethesda, MD.

The interaction between microtubule organizing centers (MTOCs) and spindle poles is critical for the establishment and maintenance of the mitotic apparatus in many organisms. However, our understanding of the dynamics of this relationship and the potential implications for tissue homeostasis remains largely unexplored. Here we report that the microcephaly-associated protein, Abnormal Spindle (Asp), plays a key role in maintaining centrosome-pole attachments and pole focusing in *Drosophila* neural stem cells. Complete loss of function mutations in *asp* cause centrosome detachment from poles shortly after metaphase, leading to free-ranging centrosomes that randomly move around the cell until anaphase onset. As a consequence, centrosome inheritance is randomized, with neural stem cells either losing their centrosome or retaining both following asymmetric division. Furthermore, we show that Asp's spindle function is dependent on the calcium-sensing protein Calmodulin (CaM). Both proteins colocalize on spindles and dynamically move towards spindle poles with similar velocities, suggesting that they form a complex with CaM acting as a regulator of Asp. Our direct binding assay and structure-function analysis of Asp support this hypothesis. However, the Asp-CaM interaction is dispensable for head and brain size, and the spindle defects observed in neural stem cells of *asp* mutants do not correlate with microcephaly phenotypes. Instead, the ability of Asp to suppress microcephaly is conferred by an unknown domain in the N-terminus of the protein through a mechanism that is currently under investigation.

D138 Local Adaptation and the Establishment of Inversions in Natural Populations of *Drosophila pseudoobscura* Through the Indirect Effects of Suppressed Recombination. *Zachary Fuller*[1], Gwilym Haynes[1], Stephen Richards[2], Stephen Schaeffer[1]. 1) Penn State, University Park, PA; 2) Baylor College of Medicine, Houston, TX.

Despite the expected homogenizing effects of extensive gene flow, the third chromosome of *Drosophila pseudoobscura* is polymorphic for > 30 gene arrangements that are distributed over a stable gradient in frequency across the American Southwest. Furthermore, no chromosome arrangement has been detected at complete fixation in any ecological niche and heterokaryotypes can form at appreciable frequencies. Inversions may become established in populations due to (1) direct effects of the inversion mutation, (2) indirect effects of suppressed recombination where different arrangements capture adaptive alleles and maintain associations of multiple selected genes, (3) the capture of a single sweeping adaptive allele, or (4) random genetic drift. We tested hypotheses regarding the establishment of inversions by sequencing the complete genomes of 54 *D. pseudoobscura* strains that include multiple copies of six common arrangements. Additionally, we quantified gene expression across three life stages and tested for differential gene expression between arrangement homokaryotypes and heterokaryotypes. We find evidence for high levels of genetic differentiation across inverted regions of the third chromosome and observe a significant overabundance of derived allele and amino acid frequency changes. The number of selected genes within an arrangement is positively correlated to the size of the inversion mutation, which is consistent with models of local adaptation that find that the size of an inversion is proportional to the number of genes contributing to local adaptation. Inverted regions also harbor significantly different patterns of gene transcription between homokaryotypes, yet in heterokaryotypes we find prevalent additive interactions of gene copies derived from different chromosome arrangements. Genes involved in odorant and sensory perception pathways are significantly enriched for both differential expression and derived amino acid changes. Our results provide evidence that inversions have become established in *D. pseudoobscura* through the indirect effects of suppressed recombination that have maintained genetic and transcriptional differences across arrangements. We further expand upon existing theory and propose a multi-locus model to explain the existence of a stable gradient as a result of local adaptation across a heterogeneous environment.

D139 *Cis*-regulatory basis of expression divergence between recent gene duplicates. *K. Tanaka*[1], L. Baudouin-Gonzalez[1], M. Santos[1], É. Sucena[1,2]. 1) Instituto Gulbenkian de Ciência, Oeiras, PT; 2) Faculdade de Ciências da Universidade de Lisboa, Lisbon, PT.

Gene duplication plays a major role in evolution of novel gene functions as it provides a material basis for selection to act upon. How *cis*-regulatory landscapes are altered after duplication events to contribute to expression divergence is not well understood. Here we address this question by studying a recent duplicate pair originating at the base of drosophilids. The *Drosophila* Ly6 genes *CG9336* and *CG9338* arose through the tandem duplication of a single ortholog still present outside Drosophilidae. Despite their recent origin, the paralogs in *D. melanogaster* have diverged in embryonic tissue-specificities from each other as well as from the unduplicated ortholog. While retaining the ancestral expression in the glia, both genes acquired a novel expression in the embryonic heart and *CG9338* alone in the hemocytes. Interestingly, these two novel expression domains are only present in subsets of *Drosophila* species examined, suggesting that their acquisitions may have been lineage-specific.

To elucidate the *cis*-regulatory basis of expression divergence, we first mapped the enhancer activities of the duplicated locus in *D. melanogaster*. We identified two enhancers driving the conserved glial expression, one located in the 3' intergenic region of *CG9336* and the other in the second intron of *CG9338*. Interestingly, the two fragments also showed activities in the heart and the hemocytes, respectively. Homologous regions from four additional *Drosophila* species all showed the conserved glial activity. However, they had a variable capacity to drive heart and hemocyte expression matching the species-specific mRNA expression. These results suggest that the pre-exiting glial enhancers inherited by each duplicate were differentially modified to acquire novel tissue-specific activities. Our study delineates a possible trajectory of enhancer evolution at a duplicated locus, which culminated in transcriptional divergence between the paralogs.

D140 Beyond the tip of the iceberg: New *Drosophila* reference genomes reveal novel structural variants. *M. Chakraborty*, Anthony Long, J. J. Emerson. University of California, Irvine, CA.

Identifying functionally important sequence variants in a genome is a key step in studying phenotypic evolution and uncovering disease causing mutations. Variation that copies, deletes, or rearranges chromosome segments has been shown both to be ubiquitous and phenotypically important. However, our ability to study such structural variation is hobbled by incomplete and fragmented genomes assembled from short reads. Recent advances in long read sequencing technology makes studying copy number variation (CNV) and transposable elements (TE) far easier, revealing a vast reservoir of genetic variation that was previously invisible. Here we report a new assembly and SV analysis of a *Drosophila melanogaster* strain, called A4, using PacBio long reads. The A4 genome is accurate, complete, and exceeds sequence contiguity of even the *D. melanogaster* reference genome assembly. Using this high quality genome, we discovered previously unknown gene sequences, like *Mitf* on chromosome 4, in the heterochromatic regions. Additionally, comparative genomics between the A4 and the reference genome ISO1 revealed a large number of CNVs, 40% of which were invisible to previous methods relying on PE Illumina data. Nearly 20% of the A4 genome is made up of TEs, with hundreds of new insertions distributed non-uniformly across the genome. In order to characterize the population genetics and phenotypic consequences of structural variation, we chose to sequence the 15 Drosophila Synthetic Population Resource (DSPR) founder strains (www.flyrils.org). We have generated a list of genetic variants, including both SNP and SV from the platinum grade DSPR assemblies. These data provide a comprehensive platform for understanding evolution and the phenotypic consequences of structural variation.

D141 Functional and evolutionary consequences of epigenetically silenced transposable elements in euchromatin. *Grace Yuh Chwen Lee*[1], Gary Karpen[1,2]. 1) Lawrence Berkeley National Lab, Berkeley, CA; 2) University of California, Berkeley, CA.

Transposable elements (TEs) are genome parasites that can increase their copy number at the expense of host fitness. Natural selection against deleterious TE insertions is a potent evolutionary mechanism for counterbalancing the constant increase in TE copy number. There is a rich understanding of the deleterious effects of TEs that are mediated by physical disruption of DNA, such as insertions of TEs into functional elements. Instead, we focus on the largely unexplored *epigenetic* consequences of TE insertions. In *Drosophila,* euchromatic TEs can be epigenetically silenced via small RNA-dependent enrichment of heterochromatic marks, which can spread to and influence the function of adjacent sequences. We hypothesized that this spread of heterochromatic marks from euchromatic TEs has deleterious functional impacts and leads to selection against individual TEs, both of which were supported by our previous genomic study. We further investigated the evolutionary consequences of TE's epigenetic effects in natural populations using wildtype *D. melanogaster* strains and the closely related *D. simulans.* In these wild-derived genomes, we also observe enrichment of heterochromatic marks in sequences adjacent to TEs, suggesting that the epigenetic effects of TEs are a general phenomenon and can have a significant role in the evolutionary dynamics of TEs in natural populations. The vastly different positions of TE insertion sites between the genomes of wildtype strains allowed for unprecedented quantification of the epigenetic effects of TEs. More than half of the TE insertions show enrichment for silencing marks in adjacent sequences. This spreading of silencing marks from TEs can extend up to 20kb (average 4kb) and lead to maximally a 2.5 fold (average 48%) increase in heterochromatic mark enrichment, demonstrating the pervasive epigenetic effects of TEs in host genomes. Importantly, TE families that show more extensive spread of heterochromatic marks have lower population frequencies, which again supports our evolutionary hypothesis. Interestingly, TE families that show significant spread of heterochromatic marks are enriched for TE families displaying recent horizontal transfer between *Drosophila* species, as well as those targeted by the endo-siRNA pathway. Furthermore, the type of TEs that show the strongest epigenetic effects is different between *D. melanogaster* (LTR TEs) and *D. simulans* (TIR TEs), which echoes the well-known differences in the predominant type of TEs in these two host genomes (LTR in *D. melanogaster* and TIR in *D. simulans*). We will report on ongoing investigation aimed at identifying the functional causes and evolutionary implications of these observations.

D142 Co-evolution within the nuclear branch of the *Drosophila* piRNA pathway. *S. Parhad*, S. Tu, B. Koppetsch, Z. Weng, W. Theurkauf. Univ Massachusetts Med Sch, Worcester, MA.

piRNA pathway protects the genome from transposons. Many piRNA pathway genes are rapidly evolving, consistent with a host-pathogen arms race between the pathway and transposons. To directly assay for the functional consequences of piRNA pathway protein evolution, we rescued null mutation in *D. melanogaster rhino (rhi)* gene with *rhi* from the sibling species *D. simulans.* The *rhino* gene encodes a rapidly evolving HP1 homolog that associates with piRNA producing loci termed clusters, and has an essential function in piRNA biogenesis and transposon silencing. Expression of *sim-rhino* fails to complement null *D. melanogaster rhi* mutants, while expression of *mel-rhino* completely restores fertility. Small RNA sequencing and RNA-seq analyses show that *sim-rhi* is equivalent to a null allele. Rhino is composed of chromo, hinge and shadow domains. We therefore swapped individual *D. simulans* domains into a *D. melanogaster*-Rhino backbone and assayed for transgenic rescue of fertility, transposon silencing, and piRNA production. Hybrid proteins carrying the *D. sim* shadow domain are equivalent to

a null allele, and mass spec analysis of proteins associated with full length and domain substitution hybrids indicate that the *D. sim* shadow domain fails to interact with Deadlock, which form a complex with Rhino and recruits additional components of the nuclear piRNA precursor processing machinery. These observations indicate that Rhino and Deadlock are co-evolving, which has generated a species-specific interface, which may be the target for transposon encoded inhibitor that drives an arms race between the piRNA pathway and mobile elements.

D143 Lineage-specific rapid gains of satellite DNA in Drosophila. *K. H. C. Wei*, A. G. Clark, D. A. Barbash. Cornell, Ithaca, NY.

Tandemly repeating DNA elements known as satellite DNA occupy significant portions of Drosophila genomes. As they are prone to cause genomic instability through non-allelic exchange, they are predominantly sequestered in the repressive heterochromatin near the centromeres and telomeres, as well as on the Y where they accumulate as the chromosome degenerates. Interestingly, the types and abundances of satellites vary dramatically between closely related species, suggesting that they are turning-over at high rates. Yet they are often ignored in genome assemblies due to low-sequence complexity and repetitiveness, leading to poor understanding of the evolutionary dynamics underlying the observed rapid changes. Here, we identify and quantify simple satellites using the program k-Seek on whole genome sequences of nine Drosophila species, spanning 40 million years of evolution. We find that very few satellites are shared across species, consistent with the expectation of rapid turn-over. However, when we determined the gains and losses of satellite DNA along the Drosophila phylogeny based on parsimony, we found that most of the interspecific differences are due to lineage-specific gains of satellites; loss events, in comparison, are extremely rare. The rates of gain also differ greatly among lineages, as some species appear to have acquired few to no satellites, while others, including those in the *melanogaster* complex, have accumulated large numbers in a relatively short time. To separately test for satellite age, we identified heterogeneity in satellites caused by mutations and found that older satellites indeed have significantly more indels than younger satellites. In addition, we identified Y-linked satellites via enrichment in males, and found that some Ys are, unexpectedly, satellite-poor, such as the young neo-Ys in the species of the *obscura* group. Our results indicate that within Drosophila species, the vast differences in satellite DNA are predominantly driven by rapid accumulations in only some species.

D144 Repetitious elements drive silencing in the *Drosophila melanogaster* genome through heterochromatin formation. *Sarah C. R. Elgin*[1], Michael Lee[1], Tingting Gu[2], Pui Pik Law[3], Richard Festenstein[3], Elena Gracheva[1]. 1) Washington University, St Louis, MO; 2) Nanjing Agricultural University, Nanjing, China; 3) Imperial College, London, UK.

Within eukaryotic genomes, repetitious sequences are often silenced. Within the *Drosophila melanogaster* fourth chromosome, the DNA transposon remnant *1360* is an effective target, promoting silencing of an adjacent *hsp70*-driven *white* gene; this results in a Position Effect Variegation (PEV) phenotype. However, outside of the fourth chromosome, PEV is only observed when the reporter construct *P*{*1360, hsp70-white*} is present within or close to a heterochromatic domain (Haynes et al 2006 Curr Biol 16: 2222-7). At the 1198 "landing pad" site at the base of chromosome arm 2L, a copy of either *1360* or *Invader4* (a retrotransposon remnant) can switch a euchromatic region to a heterochromatic one, with increased HP1a and H3K9me2; here the variegating *hsp70-white* shows a ~2-fold decrease in expression (Sentmanat & Elgin, PNAS 109:14104-9). Recently we observed that 256 copies of a 36 bp *lacO* fragment induces even stronger PEV, an ~8-fold decrease in expression of the *hsp70-white* reporter at this site. Surprisingly, *lacO* mediated silencing shows an inverse temperature effect, with a loss of silencing at lower temperatures (G. Reuter; EG). A fragment with 310 copies of the GAA triplet repeat in the 1198 site similarly results in eight-fold silencing. All three cases exhibit a loss of silencing on introduction of HP1a mutations, confirming that heterochromatin assembly is required. While mutations in the H3K9 methyl transferase *Su(var)3-9* are dominant suppressors of *1360*- and GAA_{310}-induced silencing, this is not the case for *lacO*-induced silencing at 25°C. We find that *lacO*-induced silencing, the PEV observed in the w^{m4} line, and the PEV phenotype of a reporter in the pericentric heterochromatin (118E-10 line), are all sensitive to nicotinamide, an HDAC inhibitor, supporting a general role for histone deacetylation in heterochromatin formation in Drosophila. The heterochromatin-based mechanism for silencing the tandem *lacO* repeats apparently differs in some important aspects from that used to silence TEs, while the silencing induced by GAA_{310} mimics that seen at TEs and in pericentric heterochromatin generally. Supported by NIH GM068388, NSF MCB-1243724, & NSF MCB-1517266.

D145 Establishment and maintenance of heritable patterns of chromatin structure during early embryogenesis. *S. A. Blythe*, E. F. Wieschaus. Princeton University, Princeton, NJ.

Throughout the life cycle, the functional specializations of cells and tissues are directly reflected in the patterns of chromatin structure. During embryogenesis, genetic loci involved in cell fate specification and differentiation –committed decisions that restrict a cell's developmental potential– must be packaged in such a way that they can ultimately respond to precise spatial and temporal developmental cues. Furthermore, a mechanism must exist for faithfully replicating such chromatin states in daughter cells following mitosis. We have measured by ATAC-seq how the initial patterns of chromatin structure are established and maintained during early *Drosophila* embryogenesis with three-minute time resolution for the three cell cycles preceding the midblastula transition (MBT). During this period, the embryo undergoes large-scale zygotic genome activation, and initiates the process of pattern formation. However, because such embryos are also simultaneously engaged in mitotic nuclear amplification, one longstanding question has been to what extent stable chromatin structure could be established in the context of an extremely rapid cell cycle. We find that extensive heritable chromatin structure can be established under these conditions. Over this period, thousands of genomic loci acquire chromatin accessibility at specific times, in response to different biological timing mechanisms. Enhancers, for example, are accessible from very early in development, whereas the majority of promoters acquire accessibility at or around the MBT. The majority of these promoters gain accessibility in response to the biological timer that measures the nucleo-cytoplasmic ratio and controls the onset of the MBT. In addition, we observe that once established, these patterns of accessibility

are maintained in metaphase chromatin, suggesting that the major mechanism for epigenetic inheritance of embryonic chromatin structure relies on acquisition of mitotic stability or chromatin "bookmarking".

D146 Deciphering double strand break repair in heterochromatin and euchromatin using an *in vivo* Drosophila model. *Aniek Janssen*[1], Gregory Breuer[2], Eva Brinkman[3], Annelot van der Meulen[1], Sean Borden[1], Timothy Lee[1], Bas van Steensel[3], Ranjit Bindra[2], Jeannine LaRocque[4], Gary Karpen[1,5]. 1) Biological Systems and Engineering Division, Lawrence Berkeley National Laboratory, Berkeley, California, USA; 2) Departments of Therapeutic Radiology and Experimental Pathology, Yale School of Medicine, New Haven, Connecticut, USA; 3) Division of Gene Regulation, Netherlands Cancer Institute, Amsterdam, the Netherlands; 4) Department of Human Science, School of Nursing & Health Studies, Georgetown University, Washington DC, USA; 5) Department of Molecular and Cell Biology, UC Berkeley, Berkeley, California, USA.

Repair of DNA double strand breaks (DSBs) must be properly orchestrated within the diverse nuclear chromatin regions in order to maintain genome stability. The choice between the two main DSB repair pathways: non-homologous end joining (NHEJ) and homologous recombination (HR), is dictated by the cell cycle as well as chromatin context. Constitutive heterochromatin, which forms a dense, generally transcriptionally silent structure near centromeres and telomeres, is essential for maintaining genome stability and is enriched for repetitive DNA sequences. The compact nature of this chromatin structure and the presence of many repetitive sequences make heterochromatin potentially vulnerable to erroneous DSB repair.

Several studies have revealed that heterochromatic regions display specialized temporal and spatial responses to DNA damage that differ from repair in euchromatin. Irradiation (IR)-induced damage has been shown to result in relaxation of the heterochromatin domain and relocalization of resected DSBs to outside the heterochromatin domain, where HR is thought to be the main mode of repair.

Here, we have developed an *in vivo* single DSB system specifically targeted to heterochromatic as well as euchromatic loci. We find, using live imaging of larval discs, that single DSBs can recapitulate the heterochromatin-specific spatial and temporal DSB dynamics previously seen with IR-induced breaks in cell culture.

Importantly, we identify a prominent role for both the NHEJ and HR pathways in heterochromatic DSB repair and find that the homologous chromosome can be used as a template for HR repair in both eu- and heterochromatin.

These data suggest that, although DSBs in heterochromatin and euchromatin are subject to diverse spatiotemporal dynamics, repair pathway choice is ultimately highly similar in these two distinct chromatin regions.

D147 The Drosophila Y chromosome acts as a heterochromatin sink and contributes to sex-specific aging. *Emily Brown*, Doris Bachtrog. University of California, Berkeley, Berkeley, CA.

The Drosophila Y chromosome is gene poor and primarily consists of epigenetically silenced repetitive DNA, but nonetheless influences expression of thousands of genes genome-wide, possibly by sequestering heterochromatin machinery away from other positions in the genome. To directly test the influence of the Y chromosome on heterochromatin genome-wide, we assayed the genomic distribution of histone marks associated with constitutive heterochromatin (H3K9me2 and H3K9me3) in flies with varying sex chromosome complements (XO, XY, and XYY males, and XX and XXY females). We find that the number of Y chromosomes strongly influences the genome-wide enrichment patterns of repressive chromatin marks. Highly repetitive regions are enriched for heterochromatin marks in wild-type males and females, and even more so in XO males. In contrast, additional Y chromosomes in XXY females and XYY males dilute repressive marks away from normally silenced, repeat-rich regions, which is accompanied by a de-repression of Y-linked repeats. This suggests that the Y chromosome can sequester heterochromatic factors, thus acting as a heterochromatin sink.

We also investigated the role of the Y chromosome and heterochromatin in sex-specific aging. In most XY taxa, males have a shorter average lifespan than females, and accumulating evidence suggests that chromatin mis-regulation, and particularly loss of heterochromatin associated with aberrant expression of repetitive elements, contributes to organismal aging. To investigate whether the Y chromosome's role as a heterochromatin sink could contribute to the shorter male lifespan, we collected lifepan and RNA-seq data from XY, XO, and XYY males, and XX and XXY females. Our results suggest that the Y chromosome contributes to a shorter lifespan, as individuals with a Y chromosome, independent of sex, have a shorter lifespan. Additionally, repetitive elements show greater mis-regulation during aging in individuals with a Y chromosome, especially Y-linked repeats, suggesting that the Y chromosome's influence on heterochromatin may contribute to a shorter average lifespan in males.

D148 Progenitor expansion and competence are controlled by Lsd1, PRC2 and non-coding RNAs. *M. Lee*[1,2], A. C. Spradling[1,2]. 1) Carnegie Institution of Washington, Baltimore, MD; 2) HHMI.

Progenitors must expand sufficiently to achieve final tissue size, while retaining chromatin flexible enough to produce multiple cell types yet receptive to external signals. The Drosophila follicle cell stem cell (FSC) generates daughters that divide nine times to generate a large progenitor pool ideally suited for studying progenitor differentiation. Previously, we showed that antagonistic actions between lysine-specific demethylase 1 (Lsd1) and Trithorax (TRX) methyltransferase dynamically modulate methylation levels at histone lysine 4 (H3K4) to maintain plastic epigenetic states in early progenitors that are crucial for proliferation and to time differentiation (Lee and Spradling (2014) Genes Dev . 28, 2729). Here, we further report a coordinated interaction between an Lsd1 complex and Polycomb Repressive Complex 2 (PRC2) that modifies chromatin states to time progenitor differentiation. All three PRC2 core components (i.e., E(z), ESC and Su(z)12) regulate epigenetic plasticity and modulate progenitor competence during follicle progenitor differentiation. Moreover, our evidence suggests that the Lsd1 complex and PRC2 are coordinated by noncoding RNAs. These results argue that poised chromatin states are dynamically modulated by regulating methylation levels at H3K4 and H3K27 to control cell proliferation and competence during progenitor differentiation.

D149 A somatic piRNA pathway in the *Drosophila* fat body ensures metabolic homeostasis and normal lifespan. *S. L. Helfand*, B. C. Jones, J. G. Wood, C. Chang, A. Tam, M. J. Franklin, E. Siegel. Brown Univ, Providence, RI.

Transposable elements (TEs) are mobile sequences of DNA that parasitize the genomes of their hosts. Due to their replicative ability, TEs account for large portions of their host genomes including nearly 30% of the fly genome and 45% of the human genome. To combat the invasion and expansion of TEs, small RNA (smRNA) silencing pathways have evolved to suppress TEs across species from plants to humans. Such pathways are essential in maintaining genomic integrity by preventing TE transposition that could disrupt normal gene function in otherwise healthy tissues. The Piwi-interacting (piRNA) pathway, classically associated with gonadal tissues, employs 23-29nt smRNAs complexed with argonaute proteins to actively suppress TEs in the germline of animals. However, recent evidence has begun to suggest that components of this pathway may in fact be present in somatic tissues of multiple species including flies, mice, monkeys, and humans. Here we provide evidence of a functional somatic piRNA pathway in the adult *Drosophila* abdominal fat body including the presence of the piRNA effector protein Piwi and canonical 23-29nt long piRNAs that map to TEs and piRNA clusters known to produce TE piRNAs. We also observed fat body genic piRNAs that map to 3'UTRs, another known source of piRNAs in the gonads. *piwi* mutants exhibit depletion of both TE- and 3'UTR-mapping piRNAs, increased TE transcript levels, TE transposition in the fat body, altered metabolic gene expression, and reduced lipid and glycogen reserves. Finally, *piwi* mutants are also sensitive to starvation, immunologically compromised, and have shortened lifespans, all hallmarks of compromised tissue function in the fat body. These findings demonstrate the presence of a functional non-gonadal somatic piRNA pathway in the adult fat body that impacts normal metabolism, immunological function, and overall organismal health.

D150 The sexual identity of adult intestinal stem cells controls organ size and plasticity. *B. Hudry*, S. Khadayate, I. Miguel-Aliaga. Imperial College London, London, GB.

Male and female animals often differ in their metabolism and physiology. Genetic sex determination factors are known to play a key role during development in the formation of reproductive organs and secondary sexual characteristics, which could indirectly lead to physiological differences between the sexes. However, less is known about the maintenance and possible roles of sex determination mechanisms in fully developed organs. We have used the *Drosophila melanogaster* intestine to investigate the nature and significance of intrinsic sex determination pathways in an adult somatic organ *in vivo*. We find that the adult intestinal epithelium displays extensive sex differences in expression of genes with roles in growth and metabolism. We have focused first on one cell subpopulation, the intestinal stem cells (ISCs), to characterize the molecular mechanisms involved, and to establish their functional significance. Cell-specific reversals of the sexual identity of adult ISCs uncovers that this identity has a key role in controlling organ size, reproductive plasticity and response to tumorigenic insults. Unlike previous examples of sexually dimorphic somatic stem cell activity, the sex differences in ISC behaviour arise from intrinsic mechanisms that control cell cycle duration and involve a new *doublesex*- and *fruitless*-independent branch of the sex differentiation pathway downstream of *transformer*. Together, these findings indicate that the plasticity of an adult somatic organ is reversibly controlled by its sexual identity, imparted by a new mechanism, which may be active in more tissues than previously recognized. More recently, we have extended our characterization of these sex differences to cell types other than somatic stem cells. We find that the sexual identity of different - but lineage-related - cell types in the adult fly is maintained through different mechanisms, and are currently exploring the possible metabolic significance of such mosaicism.

D151 Mechanisms underlying sexually dimorphic growth. *Annick Sawala*, Alex P. Gould. The Francis Crick Institute, Mill Hill Laboratory, London, United Kingdom.

Sexual size dimorphism (SSD) is widespread throughout the animal kingdom. In *Drosophila*, sex differences in body size arise during larval development and result in females that are 20-40% larger than males. Signalling mechanisms that regulate larval growth and final body size have been identified, but how they are differentially regulated in males and females to produce SSD is not well understood. A recent study reported that the sex determination gene *transformer* (*tra*) acts in the fat body to promote female-specific body growth (Rideout et al. 2015, PLoS Genetics). Here we show that *Sex-lethal* (*Sxl*), an upstream gene in the sex determination pathway, functions in the nervous system to upregulate female body growth in a non-autonomous manner. Nervous system-specific knockdown of Sxl in females is sufficient to convert their body to a male size, completely abrogating SSD. Conversely, female body size in *sxl* mutants can be rescued by expressing Sxl in only the nervous system. We find that Sxl functions specifically in peptidergic and GABAergic neurons to promote body growth in females. Current research focuses on mapping the Sxl neural circuitry regulating female-specific growth.

D152 Body weight dependent autophagy induction mediates metamorphic timing control under nutrient restriction in Drosophila. *Xueyang Pan*[1,2], Michael O'Connor[1]. 1) Department of Genetics, Cell Biology and Development, University of Minnesota, Minneapolis, MN; 2) Molecular, Cellular, Developmental Biology and Genetics Program, University of Minnesota, Minneapolis, MN.

In Drosophila, the timing of post-embryonic developmental transitions are finely correlated with body growth, and also respond to environmental variants such as food availability. During L3 stage, fasting condition causes arrest of metamorphic transition when larvae do not reach a body weight threshold (critical weight), however, beyond the threshold metamorphosis is no longer postponed by starvation. It is well known that insulin/TOR signaling couples nutrient condition and metamorphic timing in prothoracic gland (PG), the larva endocrine organ making the molting hormone ecdysone. However, how larva body weight poses impact on metamorphic timing control, especially during nutrient deficiency, is not clearly understood.

In this study we find that macroautophagy (hearafter autophagy), a degradative cellular process found in various larva tissues, functions in PG as a body weight sensitive controller of metamorphosis during nutrient restriction (NR). We firstly detected autophagy induction in PG during

NR, which tightly requires Atg genes and can be suppressed by insulin/TOR pathway. Intriguingly, NR-induced autophagy is only dynamic in early L3 stage but is gradually muted as larvae grow heavier. Upon autophagy suppression early L3 NR causes undersized larvae to pupariate precociously, leading to pupal lethality, whereas over-induction of autophagy causes developmental delay even in well fed larvae. Beyond confirming autophagy as a gatekeeper of metamorphosis, we further find that Anaplastic Lymphoma Kinase (Alk), a receptor tyrosine kinase, works as autophagy suppressor during late L3 NR. The Alk expression in PG keeps marginal until early L3 stage and boosts as larvae grow over the critical weight, indicating its functioning time window. Expression of constitutively active Alk in PG prevents NR-induced autophagy in early L3 stage, while knocking down Alk leaves autophagy markedly stimulated during late L3 NR. Besides autophagy, Alk activation larvae also phenocopy insulin pathway activation larvae on developmental timing and final body size, suggesting that Alk receptor may lead to similar signaling pathways to insulin receptor and thus compensate the loss of insulin signaling in PG during late L3 NR. In all, our findings uncover a novel view on how developmental timing is controlled in accordance with body growth.

D153 A SANT-like domain-containing protein regulates lipid droplet size. *X. Huang*, Y. Yao, X. Li, Z. Liu. IGDB, CAS, Beijing, Beijing, CN.

Lipid droplets are the main lipid storage sites in cells. The size of LDs varies greatly under different physiological conditions. Despite many studies reporting factors important for lipid storage, the underlying mechanisms of LD size regulation are still not fully understood. Through a large-scale overexpression screen in the *Drosophila* larval fat body, we found that a SANT-like domain-containing protein is critical for LDs size regulation. Overexpressing this protein leads to enlarged LDs, while mutations have small LDs. Proteins with SANT-like domain have been previously linked to chromatin remodeling. Here we provide multiple evidences suggest that this SANT-like domain-containing protein may links to NURF chromatin remodeling complex via interacting with PZG. Therefore, our work provides a new insight of lipid droplet size regulation.

D154 Identification and Characterization of a Novel Gene that Regulates Mitochondrial DNA Replication. *J. Tang*, Y. Zhang, H. Xu. National Institute of Health, bethesda, MD.

Mitochondrial DNA (mtDNA) replication is essential for mitochondrial function in response to developmental and physiological demand. Impaired mtDNA replication leads to developmental defects, aging and diseases. To identify novel genes involved in the regulation of mtDNA replication, we conducted an in vivo RNAi screen in *Drosophila* and identified a novel gene, EmptyHouse. We found that the protein encoded by EmptyHouse is associated with the mitochondrial inner membrane. EmptyHouse mutant has severe developmental delay and is lethal during pupa and adult stages. Genetic analysis indicates that this gene has an essential role in mtDNA replication. Loss of this gene results in impaired mitochondrial oxidative phosphorylation activity. The human homolog, WBSCR16, is one of the genes that flanking the Williams-Beuren syndrome (WBS) commonly deleted region. The function of WBSCR16 in human is completely unknown. We expressed WBSCR16 in human tissue culture cells and found it expressed in mitochondria. Knocking down WBSCR16 expression in human tissue culture significantly slows down the mtDNA replication rate. Further characterization of EmptyHouse mutant and its human homolog may provide insight into the mechanism of regulation of mtDNA replication during development and the pathogenesis of diseases.

D155 Circadian mutants lacking either *period* or *timeless* have an extended longevity phenotype due to altered mitochondrial function. *M. M. Shirasu-Hiza*, M. J. Ulgherait, C. R. Wayne, A. Chen, S. F. McAllister, M. A. Oliva. Columbia University Medical Center, New York, NY.

We found that arrhythmic mutants lacking the critical circadian regulators *period* or *timeless* exhibit extended lifespan relative to controls. Circadian rhythm is known to affect a wide range of vertebrate physiologies, including many known to impact aging and lifespan. We set out to ask if loss of circadian regulation alters longevity. Unexpectedly, we found that male *period* and *timeless* mutants are long-lived relative to controls. Focusing on male *per* mutants, we found that they do not achieve longevity by mimicking diet restriction: to the contrary, *per* mutants eat more than controls and lack changes in metabolism and signaling pathways typically associated with diet restriction and longevity. While *per* mutants appear to age more slowly than controls, as judged by intestinal and muscle health, their extended longevity is also independent of microbiota and activity. Our results suggest instead that altered mitochondrial function leads to longevity in these mutants. We observed changes in *per* mutants' mitochondrial morphology and DNA copy number that correlate with extended longevity; genetic experiments suggest that their longevity is not due to mitophagy but due to mitohormesis. We are currently investigating specific, circadian-regulated changes in mitochondrial function that underlie *per* mutants' longevity phenotype.

D156 Histidine metabolism perturbations inhibit neural tumours dependent on Myc-mediated dedifferentiation. *F. Froldi*[1], M. Szuperák[1,3], P. Pachnis[2], O. Costas[1], T. Fernando[2], A. P. Gould[2], C. Y. Cheng[1]. 1) Peter MacCallum Cancer Centre, Melbourne, Victoria, AU; 2) The Francis Crick Institute, London, UK; 3) University of Pennsylvania, Philadelphia, PA.

Metabolic rewiring is a hallmark of cancer and it is becoming increasingly clear that metabolic adaptations in tumours are not only driven by proliferative demands, but are highly context-dependent. In this study, we explore how the genetic profile of tumours determines how these respond to perturbations in amino acid metabolism. Using a combination of dietary manipulations and genetics, we show that histidine deprivation or knockdown of histidine metabolic enzymes inhibits the growth of neural tumours induced by *nerfin-1* loss of function. *nerfin-1* encodes for a zinc-finger transcription factor required to maintain neurons in a differentiated state. Upon its loss, post-mitotic neurons dedifferentiate and acquire a stem cell fate in a step-wise process that relies on Myc-dependent cellular growth. Manipulations of histidine metabolism inhibit *nerfin-1* tumour growth by reducing Myc expression and nucleolar volume, and decreasing the overall rate of dedifferentiation. Interestingly, neural tumours caused by Notch hyperactivation, which are the result of a Myc-dependent reversion of

intermediate neural progenitors to stem cells also show a similar sensitivity to histidine metabolism inhibition. In contrast, none of these perturbations have major effects upon the growth of normal neural stem cells, epithelial tumours or *prospero* mutant neural tumours. This study shows that the sensitivity of tumours to dietary manipulations depends on the tumour genetic profile but also on its origin and mode of growth. Moreover, the metabolic vulnerabilities we identified have the potential to inform the search of metabolic interventions that specifically inhibit tumours without affecting normal cells.

D157 Ecology of the gut microbiome determines fly health. *W. B. Ludington*, V. Zhang, Z. T. Guvener. UC Berkeley, Berkeley, CA.

Gut microbiome diversity is thought to be good for animal health. However, no solid body of evidence supports the generalities of that claim, and several recent papers have shown that germ free flies live longer than flies with their typical bacteria. Here we present evidence that intermediate levels of microbial diversity in the *Drosophila melanogaster* gut promote fly health even when a suitably nutritious diet is provided. We assembled a gnotobiotic fly colonized with all of the bacterial strains consistently found in our laboratory stock flies, of which there are two *Lactobacilli* and three *Acetobacter* for a total of five strains. We then measured fly development time with every possible combination of the defined bacterial strains for a total of 32 combinations. We find overall that flies colonized with any single bacterial strain are the slowest to develop, but that flies colonized by all strains are also slow to develop. On nutritionally poor diets, however, some bacteria speed up development while others are detrimental. In flies colonized with combinations of bacterial strains, benign strains can offset the effects of detrimental strains. In a limited set of gnotobiotic fly lifespan experiments, we see a similar overall trend whereby germ free flies and flies with intermediate levels of microbial diversity live the longest.

We used the gnotobiotic fly development time data to build a microbial epistatic interaction map (i.e. a food web) to determine how microbe-microbe interactions affect fly development, noting an abundance of weak interactions. Separate measurements of microbial interactions inside the fly gut indicate that detrimental bacterial strains can promote colonization by beneficial strains. These combinations are more beneficial to the fly, providing an ecological mechanism by which specific microbial interactions and not just absolute strain numbers account for the health phenotypes we observe. In vitro growth assays and bioinformatics suggest syntrophic exchange of nutrients, specifically lactic acid and B-vitamins, as the mechanisms for these microbial interactions inside the fly.

We propose that maintaining a diverse gut microbiome serves as a bet hedge against the more severe consequences of dominance by detrimental strains.

D158 Genome-wide spatial-temporal gene expression pattern prediction in Drosophila melanogaster embryonic development. *J. Zhou*[1], I. Schor[3], V. Yao[1], O. Troyanskaya[1,2], E. Furlong[3]. 1) Princeton University, Princeton, NJ; 2) Simons Foundation, New York, NY; 3) European Molecular Biology Laboratory, Heidelberg, Germany.

Spatial-temporal gene expression patterns are fundamental information for understanding embryonic developmental program and tissue-specific gene functions. High-throughput *in situ* experiments have provide abundant measurements for *Drosophila* embryogenesis, but a high proportion of protein coding genes (>5000) have not been measured and the primary output of these experiments are qualitative. A genome-wide data-integration approach will complement the current spatial-temporal *in situ* data by training machine learning models that integrate all public expression and chromatin profiling data to provide genome-wide and quantitative predictions for all genes. To systematically predict spatial-temporal expression patterns in 282 tissue-stages of *Drosophila melanogaster* embryonic development, we developed structured *in silico* nano-dissection, a computational approach that predicts tissue and developmental stage specific gene expression using cell lineage information and gene co-regulation patterns from a diverse compendium of 6,378 genome-wide expression and chromatin profiling samples. Our method employs a two-stage approach, the first stage trains a predictor for each tissue-stage category, and the second stage integrates all predictions with a global cell lineage based probabilistic graphical model. We systematically evaluated our performance on holdout genes, and validated new predictions by literature and performing new experiments. On genes without previously known spatial temporal patterns or literature evidence for tissue-specificity, we verified the predictions by new *in situ* hybridization. Among all 13 *in situ* experiments with detectable expression signal, all five predicted genes for brain primordium and eight predicted genes for embryonic muscle systems were verified. The co-expression patterns of these genes in other tissues such as gut and plasmatocytes, as well as temporal patterns across developmental stages were also correctly predicted. Furthermore, we show that our spatial-temporal expression predictions can be applied to detect the tissue specificity signals in *twi*, *mef2*, and *trh* mutant embryos, demonstrating its potential in analyzing tissue specificity signal from non-tissue-dissected experiments. Our resource together with exploratory tools are available athttp://find.princeton.edu.

D159 Measuring exercise in *Drosophila:* Characterization of the Rotating Exercise Quantification System (R.E.Q.S.). *L.Patrick. Watanabe*, Nicole Riddle. University of Alabama at Birmingham, Birmingham, AL.

Recent estimates show that more than 78.6 million adults are obese in the United States with the annual medical cost at $147 billion dollars in 2008. The most common treatments for obesity come in the form of a dietary change or an increase in physical activity (exercise). Despite the popularity of exercise as a treatment for obesity, very little is known about how an individual's genetic background impacts his/her response to exercise. This has become increasingly relevant as new studies have indicated that up to 20% of the population may be "exercise non-responders", individuals who are programmed – genetically or epigenetically – to have weak or absent metabolic responses to exercise. In order to elucidate the genetic mechanisms underlying exercise response, we have developed an innovative exercise system for *Drosophila melanogaster* named the Rotating Exercise Quantification System (R.E.Q.S.). This system allows for the real-time quantification of exercise in Drosophila. One interval and one continuous exercise regime were performed on three fly lines from the Drosophila Genetics Reference Panel 2 (DGRP2). Our results show that there is significant variability in exercise levels between these lines, enough so to perform Genome Wide

Association Studies (GWAS) using the entire panel of 200 lines to identify candidate genes. This study validates the use of rotation-based exercise and demonstrates the potential for Drosophila as a model in the field of exercise genetics.

D160 Features and Applications of FlyCircuit Database – From Fluorescent Images to the Drosophila Connectome. *C. T. Shih*[1,2], A. S. Chiang[3,4]. 1) Tunghai University, Taichung, TW; 2) National Center for High-Performance Computing, Hsinchu, TW; 3) National Tsing-Hua University, Hsinchu, TW; 4) Kavli Institute for Brain and Mind, CA.

FlyCircuit (www.flycircuit.tw) is a database containing more than 28,000 image entries of individual neurons in the Drosophila brain. The database was constructed for online data archiving, browsing, searching, analysis, and 3D visualization for the single neurons. Using the genetic mosaic analysis with a repressible cell marker (MARCM), the single neurons were labeled with green fluorescent protein (GFP). Also, the birth date during the brain development and putative neurotransmitter for each neuron could be predicted with this transgenic technique. To handle these terabytes of image data, a fully automatic image-processing workflow was introduced to reconstruct the single neurons from the fluorescent raw images to their three-dimensional digital reconstruction.

With the image data in FlyCircuit, the structural connectome of the fruit flies could be assembled at different scales. The mesoscopic connectome was composed of the brain regions called the local processing units (LPUs) and their directed and weighted links. It showed small-world characteristics, hierarchical modular structure, and rich-club organization. The network consisted of five functional modules – olfactory, auditory, left and right visual centers, and the pre-motor center. Major loops with length from three to five were identified. Many loops were found which could sustain the electrophysiological signals for a longer period.

Microscopic connectome composed of the neuron-to-neuron connections was also analyzed. The network also showed hierarchical modular structure. Interestingly, the modules were corresponding to the functional modules in the mesoscopic version, rather than the expected LPUs or neuropils in the brain anatomy. The numbers of loops with length up to six in the brain network were significantly larger than their counterparts in the random networks. Finally, rich club formed from a population of neurons with high global centrality scores was also detected.

D161 High-speed imaging of neural spiking and dendritic dynamics in awake flies with a fluorescent voltage sensor. *Cheng Huang*[1], Yiyang Gong[1,2,4], Mark Schnitzer[1,2,3]. 1) James H. Clark Center, Stanford University, Stanford, CA; 2) CNC Program, Stanford University, Stanford, CA; 3) Howard Hughes Medical Institute, Stanford, CA; 4) Duke University, Durham, NC.

Genetically encoded voltage indicators (GEVIs) are a promising technology for visualizing the millisecond-scale dynamics of specific neuron types and their fine arbors in live animals, which presently neither electrophysiological nor Ca^{2+} imaging techniques do well. For researchers studying *Drosophila*, optical voltage imaging with GEVIs offers newfound possibilities to investigate cellular and sub-cellular electrophysiological phenomena that remain largely unexplored due to the technical difficulty of *in vivo* intracellular electrical recording methods. Here, to showcase the capabilities for optical voltage imaging in the intact fly brain, we imaged neuronal voltage dynamics in several parts of the fly olfactory system using our recently developed GEVI, Ace2N-mNeonGreen (Gong *et al., Science* 2015), in which a fast voltage-sensing domain from a rhodopsin family protein is coupled to a bright protein fluorophore through resonance energy transfer. Ace2N-mNeonGreen is sufficiently bright and fast to report neural action potentials and membrane voltage dynamics in awake flies, and resolves fast spike trains with 0.2-millisecond timing precision at spike detection error rates orders of magnitude better than prior GEVIs. *In vivo* imaging revealed sensory-evoked responses, including somatic spiking, dendritic dynamics, intracellular voltage propagation, and inter-hemispheric differences in neuronal activity. These results empower *in vivo* optical studies of neuronal electrophysiology and motivate novel experimental designs that will allow researchers to relate high-speed neuronal dynamics and information processing to fruit fly behavior..

D162 Effective knockdown of *Drosophila* long noncoding RNAs by CRISPR interference. *J. L. Liu*, S. Ghosh, C. Tibbit. Department of Physiology, Anatomy and Genetics, University of Oxford, Oxford OX1 3PT, United Kingdom.

Long noncoding RNAs (lncRNAs) have emerged as regulators of gene expression across metazoa. Interestingly, some lncRNAs function independently of their transcripts - the transcription of the lncRNA locus itself affects target genes. However, current methods of loss-of-function analysis are insufficient to address the role of lncRNA transcription from the transcript which has impeded analysis of their function. Using the minimal CRISPR interference (CRISPRi) system, we show that co-expression of the catalytically inactive Cas9 (dCas9) and guide RNAs targeting the endogenous *roX* locus in the *Drosophila* cells results in a robust and specific knockdown of *roX1* and *roX2* RNAs, thus eliminating the need for recruiting chromatin modifying proteins for effective gene silencing. Additionally, we find that the human and *Drosophila* codon optimised dCas9 genes are functional and show similar transcription repressive activity. Finally, we demonstrate that the minimal CRISPRi system suppresses *roX* transcription efficiently *in vivo* resulting in loss-of-function phenotype, thus validating the method for the first time in a multicelluar organism. Our analysis expands the genetic toolkit available for interrogating lncRNA function *in situ* and is adaptable for targeting multiple genes across model organisms.

D163 Optimized synthetic lethal screening approaches for drug target discovery in *Drosophila*. *Benjamin E. Housden*[1], Alexander J. Valvezan[2], Colleen Kelley[1], Andrew P. Georgiadis[1], Yanhui Hu[1], Yuanli Wang[1], Stephanie Mohr[1], Brendan D. Manning[2], Norbert Perrimon[1,3]. 1) Harvard Medical School, Boston, MA; 2) Harvard School of Public Health, Boston, MA; 3) Howard Hughes Medical Institute, Boston, MA.

A major approach for the discovery of potential drug targets for tumorigenic disease is based around the identification of synthetic lethality. Synthetic lethality is defined as a genetic interaction where the combined disruption of two genes is lethal but either disruption alone has no

effect. Genes that have synthetic lethal interactions with tumor suppressors are attractive as drug targets for cancers because treatments will specifically kill tumor cells but will have little effect on the surrounding wildtype tissue. However, these interactions have proved difficult to identify using existing screening technologies and those that are identified are often not reproducible between screens.

We combined CRISPR and RNAi in a novel combinatorial screening method in *Drosophila* cells. Using this approach we identified almost 200 robust candidate drug targets for Tuberous sclerosis complex (TSC), a tumorigenic disease caused by mutation of either the TSC1 or TSC2 tumor suppressors. Based on this work, a promising drug is now in development for this disease. However, despite this success, overlap of hits between screens is limited, indicating that many interactions are still missed. We hypothesized that many synthetic lethal effects occur only with incomplete gene knockdown. These interactions are therefore missed in many cases because weak knockdown has no effect and strong knockdown is lethal to both mutant and wildtype genetic backgrounds. We therefore developed an approach called variable dose analysis (VDA), which uses cytometry-based analysis to profile viability effects over a range of knockdown efficiencies in a single population of cells treated with RNAi. Using VDA to compare viability profiles between wildtype and TSC mutant cells, we found that this method has reduced noise compared to previous screening approaches. We were able to detect 83% of known synthetic lethal interactions with TSC compared to only 22% using established screening technologies. This is therefore a robust method to detect synthetic lethality that will likely be applicable to the identification of drug targets for many tumorigenic diseases.

D164 CRISPR/Cas9-based tools for *in vivo* transcriptional activation and repression in *Drosophila*. *B. Ewen-Campen*[1], Lu-Ping Liu[1], Rong Tao[1], Donghui Yang-Zhou[1], Shauiliang Lin[1], Xingjie Ren[3], Sun Jin[3], Jian-Quan Ni[3], Shu Kondo[4], Norbert Perrimon[1,2]. 1) Harvard Medical School, Boston, MA; 2) Howard Hughes Medical Institute; 3) Medicine, Tsingua University, Beijing, China; 4) National Institute of Genetics, Mishima, Shizuoka, Japan.

CRISPR/Cas9-based transcriptional activation (CRISPRa) and repression (CRISPRi) provide a powerful new set of tools for studying gene function *in vivo*. A major advantage of these systems is that any gene-of-interest can be targeted using a ~20bp guide RNA, making this approach versatile and scalable. However, several different dCas9-fusions and sgRNA design rules have recently been published, and the most effective approaches have not been defined. In this study, we directly compare different dCas9-fusion proteins for both CRISPRa and CRISPRi *in vivo*, and identify highly effective approaches for each. We also present a growing collection of publically available *Drosophila* stocks for activating and repressing target genes in various tissues. Together, these studies lay a foundation for our ongoing effort to generate a genome-wide resource for CRISPRa and CRISPRi for the *Drosophila* community.

D165 A novel 96 well system for housing, manipulating and feeding flies. *M. D. Jaime*, B. Oliver. National Institutes of Health , Bethesda, MD.

The sophisticated genetic tools available in *Drosophila*, coupled with the evolutionary conservation of biological processes found in higher organisms, including humans, should encourage the use of whole organism in drug discovery, diet, and toxicology. For high-throughput work, this requires plate formats compatible with standard equipment, minimization of handling, and low volume feeding. To meet these design specifications, we have developed a 3D printed 96-well system called the Whole Animal Feeding Flat (WAFFL). The WAFFL is an apparatus that enables the housing and feeding of flies while reducing the number of manipulations. It has four main units for: 1) food 2) feeder (housing) 3) receiver and 4) transfer adapter. The liquid food (<10ul) is provided to the fly in a round bottom 96 well plate. The feeder plate is an array of 96 deep square shaped chambers where a single fly is housed that tightly fits into the food plate. The feeder plate includes inner ledges upon which a housed fly can perch while extending its proboscis through narrow capillary ports with liquid food. Cameras integrated into the system allow monitoring of behavior. The transfer adapter allows the interconnection of the chambers of the feeder plate to a receiver plate to harvest the flies by centrifugation to a standard deep well plate for homogenization and assay preparation. The WAFFL facilitates the transfer of flies from one condition to another in seconds by simply placing the feeder plate on a different microplate with the condition of interest without disturbing the flies. To ensure that compound doses are delivered at the same time, we used 6 hr treatments on starvation media, followed by 1 hr of feeding. A bolus of food (with dye) was observed and transit time through the gut is < 3 hrs. We have performed several small screens (600 - 800 flies) for exposure to dimethyl sulfoxide (DMSO), ethanol, and different diets. We will present time-course results (~600 flies) on the effect of DMSO on gene expression profiles following exposure to different concentrations of DMSO .The scalable WAFFL system allows for automated handling of individual flies exposed to different foods, drugs, and compounds, providing a unique high-throughput platform for drug screening in flies. The WAFFL and flies are a limitless discovery duo.

D166 Neuronal 3'UTR extension: ELAV links Pol II pausing to alternative polyadenylation. *V. Hilgers*[1], K. Oktaba[1], W. Zhang[1], D. Rio[1], M. Levine[2]. 1) University of California, Berkeley, Berkeley, CA; 2) Princeton University, Princeton, NJ.

Alternative polyadenylation (APA) has been implicated in a variety of developmental and disease processes. A particularly dramatic form of APA occurs in the developing nervous system of flies and mammals, whereby approximately 200 developmental genes undergo coordinate 3'UTR extension. The RNA-binding protein ELAV inhibits RNA processing at proximal polyadenylation sites, thereby fostering the formation of these exceptionally long 3'UTRs.

We found that paused Pol II promotes recruitment of ELAV to its target genes. Replacing promoters of extended genes with heterologous promoters blocks normal 3' extension in the nervous system, while extension-associated promoters can induce 3' extension in ectopic tissues expressing ELAV. Computational analyses show that promoter regions of extended genes tend to contain paused Pol II and associated cis-regulatory elements such as GAGA. ChIP-Seq assays identify ELAV in the promoter regions of extended genes. We provide the first evidence for a regulatory link between promoter-proximal pausing and APA.

Neuron-specific APA is conserved in humans. 3'UTR extensions are enriched in conserved regulatory motifs, indicating that extended mRNAs play a specific role in the regulatory networks that drive neural development and brain function. Our functional genetics studies reveal that deleting 3'UTR extensions in Drosophila results in diverse phenotypes such as neurodegeneration and life span lengthening.

D167 Mutant rescue by inhibition of nonsense mediated decay. *Mark M. Metzstein*. Univ Utah, Salt Lake City, UT.

The nonsense mediated mRNA decay (NMD) pathway targets and degrades mRNAs containing premature termination codons (PTCs). NMD often exacerbates the effects of nonsense mutation containing alleles by preventing the expression of partially-functional truncated proteins. As such, inhibition of NMD is considered to be a broadly applicable approach for treating numerous inherited diseases. In cases in which the truncated protein does not retain function, NMD inhibition may be synergistic with "readthrough" therapy: the administration of drugs that stimulate ectopic translation of PTCs, thus producing full length proteins.

However, before such an approach can be realized, the endogenous roles of the NMD pathway must be understood. In particular, loss of NMD is in itself completely lethal to most organisms, including *Drosophila*, probably because of a role of the NMD pathway in inhibiting the expression of a number of endogenous (non-mutated) transcripts. Recently, we have shown that this requirement of NMD for viability is due to degradation of only a single endogenous NMD target: the mRNA of the stress response gene *Gadd45* (Growth Arrest and DNA Damage)*. In particular, we have found deletion of *Gadd45* can rescue *Drosophila* carrying null mutations in core NMD genes to adulthood.

Based on these findings, we are now in the position to test whether administration of readthrough drugs does indeed work synergistically with loss of NMD in restoring functional protein expression of PTC-containing genes. To do this, we will combine known stop-codon containing alleles with mutations in NMD genes, while simultaneously suppressing NMD mutant lethality using the *Gadd45* deletion. This will be done both with and without drug-induced stop codon readthrough. Ultimately, our data should reveal the underlying relationship between RNA degradation and translation in regulating gene expression of mutated genes, in both an experimental and clinical setting.

*"Degradation of *Gadd45* mRNA by nonsense-mediated decay is essential for viability". Nelson *et al*. (**2016**) *eLife*, In press.

D168 The *Drosophila* hnRNP F/H homolog, Glorund, Uses Two Distinct RNA Binding Modes to Differentially Regulate its Targets. *E. R. Gavis*[1], J. V. Tamayo[1], T. T. Teramoto[2], T. M. T. Hall[2]. 1) Department of Molecular Biology, Princeton University, Princeton, NJ; 2) Laboratory of Structural Biology, National Institute of Environmental Health Sciences, National Institutes of Health, Research Triangle Park, NC.

Post-transcriptional gene regulation by RNA-binding proteins has proved crucial for developmental events including establishment and patterning of body axes, asymmetric cell fate decisions, and morphogenesis. Among RNA-binding proteins, heterogeneous nuclear ribonucleoproteins (hnRNPs) are notable for their ability to interact with numerous target RNAs and function in multiple aspects of RNA metabolism. The basis for this functional diversity is poorly understood, however. We previously identified Glo as an ovarian repressor of *nanos* (*nos*) translation through its interaction with a double-stranded UA-rich motif in the *nanos* 3' untranslated region (3'UTR). In contrast, human hnRNP F/H proteins are best known for their role in the regulation of alternative splicing through their interaction with single-stranded G-tract sequences. Consistent with this, we have also uncovered a potential role for Glo as a splicing factor. To investigate the multifunctionality of Glo, we determined the crystal structures of Glo's three quasi-RNA recognition motifs (qRRMs) and performed a structure/function analysis. We found that Glo qRRMs recognize G-tracts similarly to hnRNP F but recognize the UA-rich motif in *nos* through a second, noncanonical RNA-binding interface. By assaying the effect of mutations that disrupt each recognition mode *in vitro* on Glo function *in vivo*, we demonstrated that regulation of a subset of Glo's targets *in vivo* is mediated solely using the G-tract binding mode whereas regulation of *nos* requires both modes of recognition. This latter result led to the identification a G-tract in the *nos* 3'UTR that mediates Glo binding and is indeed required for *nanos* regulation. Finally, we establish that Glo's requirement for both RNA binding modes to regulate *nos* translation reflects a requirement for both motifs in the *nos* 3'UTR.

D169 The TREX complex suppresses piRNA precursor splicing and promotes assembly of piRNA cluster heterochromatin. *G. ZHANG*, Shikui Tu, Zhiping Weng, William Theurkauf. UMass Medical School, Worcester, MA.

The PIWI interacting RNA pathway silences transposons and maintains genome integrity during germline development. In *Drosophila*, piRNA precursors are generated from discrete genomic loci, called piRNA clusters. The nuclear factors Rhino, Cutoff and Deadlock appear to be dedicated to processing germline cluster transcripts in *Drosophila* ovaries, and all three proteins localize to germline cluster chromatin. Germline cluster transcripts are not spliced, and mutations in *rhino, cuff* and *deadlock* that block piRNA production also lead to cluster transcript splicing. UAP56 is an ATP dependent RNA binding protein that functions in general mRNP biogenesis. We previously showed that UAP56 interacts with piRNA precursors and that a point mutation in UAP56 (*uap56-sz15*) predicted to weaken RNA binding specifically disrupts piRNA biogenesis and increases cluster transcript splicing. The THO complex and UAP56 forms the evolutionarily conserved TREX (transcription/export) complex. Using immunoaffinity purification and mass spectroscopy from fly ovaries lysate, we confirm the *Drosophila* UAP56 interacts with the THO complex. Significantly, we also show that this point mutation in *uap56-sz15* significantly reduces binding to the THO complex. We also show that THO complex components co-localize to nuclear foci with Rhino. Similar to UAP56, THO complex binds specifically to unsplicing cluster transcripts. Mutation in *thoc7,* one of the core components of the THO complex, disrupts localization of Rhino, Cuff and UAP56. It also blocks piRNA production and leads to global defects in transposons silencing. In addition, *thoc7* mutation increases cluster transcript splicing. We propose that stable cluster transcripts binding by the TREX complex is required to suppress piRNA precursor splicing, and promotes cluster chromatin assembly.

D170 From egg to adult: piRNA-mediated silencing throughout germline development in *Drosophila melanogaster*. *P. Marie*, S. Ronsseray, A. Boivin. IBPS, CNRS, Universite Pierre et Marie Curie, Paris, France.

In metazoan germ cells, transposable element activity is repressed by small noncoding PIWI-associated RNAs (piRNAs). Numerous investigations in *Drosophila* have enlightened the mechanism of this repression in the adult germline. However, very little is known about piRNA-mediated repression during germline development. Nevertheless, to maintain the integrity of the genome, repression should occur throughout lifespan of germ cells. Here, we show that piRNA-mediated repression is active in the female germline from late embryonic to pupal primordial germ cells, and that genes related to the adult piRNA pathway are required for repression during development. *rhino*-dependent piRNAs exhibiting the molecular signature of the piRNA pathway "ping-pong" amplification step are detected in larval gonads. Furthermore, as in adult ovaries, we can observe an incomplete, bimodal and stochastic repression resembling variegation at all developmental stages. We strongly suggest, using clonal analyses, that this variegation reflects a cellular memory of an early repression decision taken in embryonic germ cells. This study shows that piRNAs and their associated proteins are the epigenetic components of a continuous repression system throughout germ cell development.

D171 Nano-exons in Drosophila. *Stephen M. Mount*[1,2], Yifei Shi[1,2], Ashley E. Nazario-Toole[1,3], Louisa Wu[1,3]. 1) Dept. Cell Bio. & Mol. Genetics, University of Maryland, College Park, MD; 2) Center for Bioinformatics and Computational Biology, University of Maryland, College Park, MD; 3) Institute for Bioscience and Biotechnology Research, University of Maryland, MD.

Nano-exons are exons less than 4 nt. long. Because nano-exons are so small, they often go undetected, and the number of nano-exons remains unknown. We have examined a single high-quality RNA-seq data set in depth using a bioinformatics pipeline to discover and quantify nano-exons. These data are derived from Drosophila hemocytes, both wild-type and expressing an *A2bp1* RNAi transgene. *A2bp1* is a member of the highly conserved Fox-1 family of RNA-binding proteins. Human homologs *RBFOX1*, *RBFOX2* and *RBFOX3* have been linked to brain development, cardiac function, and autism spectrum disorders, and have been implicated in the regulation of microexons less than 51 nt. in humans. Our analysis has revealed new potential nano-exons in Drosophila, including eight previously undescribed nano-exons with strong support. We also found three likely cases of recursive splicing with deletion that can be considered to be exons of size -1, meaning that sequences within an intron, including the sequence AGT, result in the removal of one nucleotide due to recursive splicing. Each of these three cases (in *Rpl8*, *orb* and *Axn*) occurs within highly conserved 5' UTR sequences, but their regulatory significance remains unknown. Ongoing research explores the occurrence of nano-exons in other Drosophila data sets and in other species.

D172 Identifying genetic modifiers of FUS toxicity in a drosophila model of ALS. *Udai Pandey*[1], John Monaghan[1], Daniel Johnson[2], Lawrence Reiter[2], Ian Casci[1]. 1) University of Pittsburgh Medical Center, Pittsburgh, PA; 2) University of Tennessee Health Science Center.

Amyotrophic lateral sclerosis (ALS) is the most common form of Motor Neuron Disease, and is characterized by the loss of both upper and lower motor neurons. Recently, mutations in genes that code for RNA-binding proteins have been linked to ALS pathology, suggesting that perturbation of RNA metabolism may be the cause of disease onset. Mutations of the gene Fused in Sarcoma (*FUS*), which codes for the protein FUS, have been linked to both familial and sporadic forms of ALS. FUS is a DNA/RNA-binding protein that plays critical roles in RNA metabolism including RNA trafficking and alternative splicing. While investigating the molecular mechanisms of FUS in ALS, the following observations emerged that have formed the foundation of our ongoing research program. We found that RNA binding abilities of FUS are required for causing neurodegeneration, cytoplasmic mislocalization, and incorporation of mutant FUS into cytoplasmic RNA granules (also called stress granules). We observed that ALS-causing mutations perturb the ability RNA granules to rapidly disassemble as compared to control preventing the proteins and RNA constituents to dissociate in the cytoplasm.

Using a *Drosophila melanogaster* model for FUS-associated ALS that was developed by our laboratory, we performed an unbiased genetic screen to identify modifiers of ALS-associated phenotypes. One gene identified in this screen, muscleblind (*mbl*), is the *Drosophila* homolog of human muscleblind-like (*MBNL*). MBNL is also an RNA-binding protein involved in regulating alternative splicing. Muscleblind-like proteins have been linked to several neurodegenerative diseases, and understanding how MBNL can modulate FUS toxicity in ALS will help to elucidate its role in other diseases, including myotonic dystrophy, Huntington's disease and spinocerebellar ataxia. We found that RNAi-mediated knockdown of *Drosophila* mbl rescues neurodegenerative phenotypes caused by ALS-associated mutant FUS in our model. We performed RNA sequencing using *Drosophila* brains expressing WT or mutant FUS with or without *mbl* to understand molecular mechanisms of mbl mediated suppression. Our RNA sequencing approach identified several genes whose expression is altered when FUS is overexpressed, and subsequently returned to almost normal following knockdown of endogenous mbl. Quantitative, reverse transcription, polymerase chain reaction (Q-RT-PCR) confirmed expression changes of identified genes. Taken together, the results of these experiments not only provide new insights into the mechanisms by which mutant FUS is toxic in patients with ALS, but they will also have broader implications for other related neurodegenerative diseases.

D173 A high-throughput pipeline for the production of synthetic antibodies for analysis of ribonucleoprotein complexes. *J. D. Laver*[1], H. Na[1], J. Jeon[1], F. Singh[1], K. Ancevicius[1,2], Y. Fan[1], W. X. Cao[1], K. Nie[1], Z. Yang[1], H. Luo[1], M. Wang[1,3], O. Rissland[1,3], J. T. Westwood[2], P. M. Kim[1], S. S. Sidhu[1], C. A. Smibert[1], H. D. Lipshitz[1]. 1) University of Toronto, Toronto, Ontario, CA; 2) University of Toronto at Mississauga, Mississauga, Ontario, Canada; 3) Hospital for Sick Children, Toronto, Ontario, Canada.

Post-transcriptional regulation of mRNAs plays an essential role in the control of gene expression. mRNAs are regulated in ribonucleoprotein (RNP) complexes by RNA-binding proteins (RBPs) along with associated protein and noncoding RNA (ncRNA) cofactors. A global understanding of post-transcriptional control in any cell type requires identification of the components of all of its RNP complexes. We have previously shown

that these complexes can be purified by immunoprecipitation using anti-RBP synthetic antibodies produced by phage display. To develop the large number of synthetic antibodies required for a global analysis of RNP complex composition, we have established a pipeline that combines (i) a computationally aided strategy for design of antigens located outside of annotated domains, (ii) high-throughput antigen expression and purification in *Escherichia coli*, and (iii) high-throughput antibody selection and screening. Using this pipeline, we have produced 279 antibodies against 61 different protein components of *Drosophila melanogaster* RNPs. Together with those produced in our low-throughput efforts, we have a panel of 311 antibodies for 67 RNP complex proteins. Tests of a subset of our antibodies demonstrated that 89% immunoprecipitate their endogenous target from embryo lysate. We have successfully used synthetic antibodies in RNA co-immunoprecipitation experiments to identify the entire complement of mRNAs associated with each of three different RBPs – Staufen, Pumilio, and Brain Tumor – analysis of which provided significant insights into the functions of each of these proteins. This panel of antibodies will therefore serve as a valuable resource for global studies of RNP complexes in *Drosophila*. Furthermore, our high-throughput pipeline permits efficient production of synthetic antibodies against any large set of proteins.

D174 Intercellular Ca^{2+} transients integrate spatiotemporal morphogenetic patterning in the *Drosophila* wing imaginal disc. *Qinfeng Wu*, Pavel Brodskiy, Cody Narciso, Jeremiah Zartman. University of Notre Dame, Notre Dame, IN.

Tissue development requires instructive input from multiple morphogenetic signals. To guide cellular decision making, cells must correctly integrate these diverse signals as well as coordinate behavior with their neighbors. Calcium (Ca^{2+}) is a ubiquitous second messenger that plays important roles in many physiological activities such as fertilization, proliferation and apoptosis and is regarded as a central signal integrator. While extensive work has identified core components of Ca^{2+} signaling, the regulation between Ca^{2+} signaling and morphogen pathways is still poorly understood. Here we report a novel phenomenon of oscillating, intercellular Ca^{2+} transients (ICT) in *Drosophila* wing imaginal discs, and their relation to morphogen signaling. We found that the ICT exhibits a patterned behavior, both spatially and temporally. We have elucidated the Ca^{2+} pathway components that are responsible for ICT through a combination of genetic and chemical perturbations using an *ex vivo* imaging assay. We also demonstrated that Ca^{2+} dynamics are modulated by signaling pathways including Bone Morphogenetic Protein (BMP) and Hedgehog (Hh) signaling. These observations lead to a working model of Ca^{2+} signaling as a mediator of signal integration for morphogen pathways.

D175 Rewiring regulatory feedback in BMP morphogen signaling. *J. Gawlik*[1,2], A.-H. Springhorn[1,2], G. Pyrowolakis[2,3]. 1) Spemann Graduate School for Biology and Medicine (SGBM), Freiburg, Germany; 2) BIOSS-Centre for Biological Signalling Studies, Freiburg, Germany; 3) University of Freiburg- Institute of biology I, Freiburg, Germany.

Proper growth and patterning of tissues and organs require tight control of intercellular signaling which is assured by the existence of different feedback regulatory mechanisms. We are interested in identifying the impact of feedback regulators in BMP morphogen signaling and their influence on the establishment and maintenance of graded signaling. In Drosophila BMP morphogen signaling one regulatory feedback loop involves the BMP receptor Thickveins (Tkv). In the wing imaginal disc, BMP dependent transcriptional repression of tkv keeps the level of the receptor low near the source of the BMP ligand Decapentaplegic (Dpp). This allows efficient spreading of the ligand and the formation of a long range Dpp gradient. In contrast, in the haltere precursor, the evolutionary homologue of the wing, the Hox gene Ubx disables BMP from repressing tkv and high receptor levels trap the ligand and restraint its spreading. The resulting short-range Dpp gradient has been suggested to contribute to the smaller size of the haltere. We will report on the molecular circuit implementing differential tkv regulation. In particular, we will show how BMP target genes, previously assigned as effectors of the pathway, interact with Ubx and with cis–elements on tkv regulatory modules to differentially affect tkv transcription in the wing and haltere precursors. Based on our cis-analysis we use genome editing approaches to actively reshape tkv expression, the shape of the Dpp gradient and final organ size *in vivo.* Our results provide insights on the mechanisms by which evolution rewires regulatory feedback circuitry to produce signaling gradients of new shapes and, consequently, organs of different size and ultimately new function.

D176 Minibrain and Wings apart control organ growth and tissue patterning through downregulation of Capicua. *L. Yang*[1], S. Paul[1], K. Trieu[1], F. Froldi[2], K. Harvey[2], L. Cheng[2], G. Jimenez[3], S. Shvartsman[4], A. Veraksa[1]. 1) Umass Boston, Boston, MA; 2) Peter MacCallum Cancer Centre, East Melbourne, VIC, Australia;; 3) Institut de Biologia Molecular de Barcelona-CSIC, and Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain; 4) Princeton Univ., Princeton, NJ, USA.

The transcriptional repressor Capicua (Cic) controls tissue patterning and restricts organ growth, and has been recently implicated in several cancers. Cic has emerged as a primary sensor of signaling downstream of the receptor tyrosine kinase (RTK)/extracellular signal-regulated kinase (ERK) pathway, but how Cic activity is regulated in different cellular contexts remains poorly understood. We found that the kinase Minibrain (Mnb, ortholog of mammalian DYRK1A), acting through an adaptor protein Wings apart (Wap), physically interacts with and phosphorylates the Cic protein. Mnb and Wap inhibit Cic function by limiting its transcriptional repressor activity. Downregulation of Cic by Mnb/Wap is necessary for promoting the growth of multiple organs, including the wings, eyes, and the brain, and for proper tissue patterning in the wing. We have thus uncovered a previously unknown mechanism of downregulation of Cic activity by Mnb and Wap. This mechanism operates in parallel to ERK-dependent control of Cic, indicating that Cic functions as an integrator of upstream signals that are essential for tissue patterning and organ growth. Finally, since DYRK1A and CIC exhibit, respectively, pro-oncogenic versus tumor suppressor activities in human oligodendroglioma, our results raise the possibility that DYRK1A may also downregulate CIC in human cells.

D177 Muscle derived TGF-β growth factor Myoglianin regulates size of imaginal wing discs. *Ambuj Upadhyay*, Aidan Peterson, Michael O'Connor. University of Minnesota, Minneapolis, MN.

How the size of animal appendages are coordinated to scale with body size has been a longstanding question in developmental biology. We are using the *Drosophila* wing imaginal disc as a model to identify novel genes and mechanisms which finely tune this process. In the wing imaginal disc, Decapentaplegic (Dpp), a member of the Transforming Growth Factor β (TGF- β) superfamily of ligands and homologous to vertebrate Bone Morphogenic Protein (BMP) 2/4, signaling plays a crucial role in regulating organ size and patterning. In contrast, little is known about the related branch TGF-β/Activin pathway in regulating organ size. Here we show that *myoglianin* (*myo*), a TGF-β/Activin ligand, is required for proper growth of wing, haltere, and leg imaginal discs. The smaller imaginal discs of *myo* mutants phenocopies *baboon*, the TGF-β/Activin Type-I receptor, mutants. Using tissue specific RNAi we show that only Baboon-a isoform, but not Baboon-b or Baboon-c, is required for growth. Surprisingly, we also found that only the muscle derived Myoglianin, but not the glial derived, is required for proper growth of the wing disc. In summary, our work has identified a novel function of Myoglianin in wing disc growth control. More importantly this study highlights how the size of appendages like the insect wing can be modulated by structural organs like the body wall muscle using long range TGF-β ligands. In our future studies we will explore the intracellular molecular mechanism of Myo and Baboon signaling to determine whether they feed into the same pathways as the Dpp branch. .

D178 The Drosophila tumor suppressor Tid/Alg3 controls TNFR/JNK signaling through glycosylation. *Geert de Vreede*[1,4], Holly Morrison[2], Ditte Andersen[3], Julien Colombani[3], Pierre Leopold[3], David Bilder[1]. 1) Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA; 2) Department of Pediatrics, University of California, San Francisco, San Francisco, CA; 3) University of Nice-Sophia Antipolis, CNRS, INSERM, Institute of Biology Valrose, Parc Valrose, Nice, France; 4) Developmental Biology, Utrecht University, Utrecht, The Netherlands.

Drosophila tumor suppressor genes have given great insight into the control of tissue size by cell signaling and organization. However, the molecular events required for appropriate organ growth remain poorly understood. Here we report that the Drosophila tumor suppressor *tumorous imaginal discs (tid)*, whose phenotypes were previously attributed to mutations in a DNAJ-like chaperone, are in fact driven by the loss of the N-linked glycosylation pathway component ALG3. *tid/alg3* imaginal discs display tissue architecture defects and moderate overgrowth, sharing characteristics of both 'neoplastic' and 'hyperplastic' mutants. Apicobasal polarity is largely intact, but growth-promoting Hippo signaling is upregulated, and suppressing Yki blocks tumorous overgrowth. Aberrant Yki activity results from excess JNK signaling through the recently described TNF receptor homolog Grindelwald (Grnd), and requires the Eiger/TNF ligand. Interestingly, Grnd contains an N-linked glycosylation site in its ligand binding domain, while loss of N-linked glycosylation alters Egr-Grnd signaling and leads to ectopic Grnd activation in *tid/alg3* mutant discs. Our results suggest that TNFR glycosylation modulates JNK signaling through modifying ligand-receptor interactions, opening up a potential model for general TNFR signaling regulation.

D179 A kinome-wide RNAi screen in *Drosophila* glia and human GBM models reveals Stk17A drives neoplastic glial proliferation. *Joanna Wardwell-Ozgo*[1], Colleen Mosley[1], Harley Kormblum[2], Renee Read[1]. 1) Emory University School of Medicine, Atlanta, GA; 2) Intellectual and Developmental Disabilities Research Center, The Jonsson Comprehensive Cancer Center and Departments of Psychiatry, Molecular and Medical Pharmacology, and Pediatrics, David Geffen School of Medicine, University of California Los Angeles,.

Glioblastoma multiforme (GBM), the most common primary malignant brain tumor, is highly proliferative, diffusely invasive, and incurable by current therapies. Genetic and molecular analyses reveal that GBMs frequently harbor activating mutations in the EGFR receptor tyrosine kinase (EGFR) and Phosphoinositide 3-kinase (PI3K) signaling pathways. While the ability of these mutations to drive gliomagenesis has been verified in mouse models, current data also reveal that EGFR and PI3K signaling cooperates with as yet unknown factors to drive tumor pathology in GBM. To uncover novel genes that augment EGFR- and PI3K- dependent neoplasia, we leveraged use of our novel *in vivo Drosophila* glioma model and performed a cross-species, multidisciplinary genetic modifier screen in both *Drosophila melanogaster* and mammalian GBM model systems that identified multiple suppressors of neoplastic growth including, drak, a cytoplasmic serine-threonine kinase.

Our preliminary results in both *Drosophila* and mammalian GBM model systems indicate that drak and its human ortholog, Stk17A, is necessary for GBM cell proliferation. Our data also illustrate that overexpression of drak in combination with oncogenic EGFR mutations is sufficient to promote increased glial cell proliferation. Furthermore, in our *in vivo Drosophila* model, we find that drak overexpression stimulates increased phosphorylation and activity of spaghetti squash (sqh), non-muscle myosin II regulatory light chain, a known drak substrate and key regulator of the cell cycle and cellular motility, which itself is required for neoplastic glial transformation. Finally, oncogenomic analysis of GBMs and other gliomas reveal that Stk17A becomes overexpressed in association with EGFR mutations, and Stk17A copy-gain and overexpression are significantly associated with poor prognosis in patients.

Together, our data suggest that drak potentiates the oncogenenic effects of EGFR through the upregulation of sqh activity and suggests that Stk17A may serve as a novel therapeutic target for EGFR-PI3K dependent GBMs and high-grade gliomas. Current work is aimed at furthering our understanding of drak/Stk17A's contribution to tumor pathology. We are specifically exploring the molecular function of drak/Stk17A and the signaling pathways in which drak/Stk17A enacts oncogenic transformation.

D180 Wnt proteins serve as directional cues for the Par-complex polarity and the *Drosophila* nervous tissue growth. *S. Yoshiura*, F. Matsuzaki. RIKEN CDB, Kobe, Hyogo, JP.

Correct orientation of cell polarity and division is important for the directional tissue growth and morphogenesis, but the mechanism underlying this process is remained unclear. Here, we identified multiple Wnt proteins act as directional cues to regulate the orientation of the

cell polarity and division of *Drosophila* neural stem cells, leading to the correct orientation of the nervous tissue growth. Wnt proteins play essential roles in the efficient formation and orientation of the Par-complex polarity in the neural stem cells through Frizzled/beta-Catenin signaling, which in turn dictate the central-to-peripheral polarity of the nervous tissue. Our results unveil the novel function of the Wnt signaling in the regulation of the tissue morphogenesis.

D181 Motile stem cells exhibit tissue-level spatial order during homeostasis but not growth of the adult *Drosophila* midgut. *X. Du*, J. Martin (co-first), S. Balachandra, I. Riedel-Kruse, L. O'Brien. Stanford University, Stanford, CA.

Many self-renewing, solid organs contain stem cell populations that are dispersed throughout the expanse of the tissue. Spatial dispersal ensures that each tissue field contains stem cells. How dispersed stem cells maintain proper spacing during organ renewal is unknown. Here we combine quantitative spatial analyses with long-term live imaging to investigate the underlying basis of stem cell spacing. Comprehensive statistical maps of stem cell-stem cell distances reveal that stem cells are spatially ordered during steady-state organ renewal, but not during adaptive organ growth. Overnight imaging of midguts within living animals, together with tissue-wide cell tracking and spatio-temporal analysis of individual cell displacements, shows that stem cells are autonomously motile. Individual cells, propelled by actin-rich protrusions, flatten and slither beneath the basal epithelium. At the population level, stem cell motility appears stochastic in frequency and direction. Progenitor-specific depletion of motility factors disrupts the spatial ordering of stem cells, implying that motility is needed for tissue-level dispersal. Our findings show that spatial order is a hallmark of steady-state but not expanding stem cell populations and suggest that autonomous motility is involved in stem cell distribution during tissue homeostasis.

D182 Identification of Alzheimer's disease as a neurodegenerative laminopathy. *Bess Frost*[1], Farah Bardai[2], Mel Feany[2]. 1) University of Texas Health Science Center, San Antonio, TX; 2) Brigham and Women's Hospital, Boston, MA.

Hutchinson-Gilford progeria syndrome (HGPS) is a fatal disorder involving the appearance of accelerated aging in young children. HGPS is caused by a mutation in the lamin A gene, *LMNA*, the study of which has provided fundamental insights into basic cellular biology and the biology of normal aging. Cellular consequences of lamin dysfunction in progeria and other "laminopathies" resulting from mutations in *LMNA* include invaginations and herniations of the nuclear envelope and relaxation of heterochromatic DNA. The segmental nature of progeria has been a longstanding mystery in aging research: certain aspects of aging appear to be recapitulated in the syndrome, while others, particularly neurodegeneration, are not. We have found that acquired lamin misregulation though aberrant cytoskeletal-nucleoskeletal coupling mediates neuronal death in a *Drosophila* model of Alzheimer's disease and related tauopathies. In addition, we observed robust alterations in the nuclear lamina in neurons from patients with Alzheimer's disease. To demonstrate definitively that lamin dysfunction can promote brain aging, we depleted lamin function genetically in the *Drosophila* nervous system and observed markedly decreased lifespan accompanied by age-dependent neurodegeneration. Our findings challenge the paradigm that the brain is resistant to lamin dysfunction, and identify new avenues for the therapeutic treatment of Alzheimer's disease and related tauopathies.

D183 Defects in synaptic vesicle endocytosis are caused by TDP-43 dependent translation inhibition in a Drosophila model of ALS. *A. Coyne*, J. Johannesmeyer, D. Zarnescu. University of Arizona, Tucson, AZ.

Amyotrophic Lateral Sclerosis (ALS) is a progressive neurodegenerative disease affecting upper and lower motor neurons. TDP-43, an RNA binding protein linked to the majority of ALS cases, is involved in several aspects of RNA metabolism. Using a *Drosophila* model of ALS based on TDP-43 we have previously identified a role for TDP-43 in the translation regulation of specific mRNA targets. Here we use a combination of genetic, molecular, and imaging approaches to show that TDP-43^{G298S} but not TDP-43^{WT} regulates the translation of *hsc70-4* mRNA. Hsc70 is a molecular chaperone that functions at multiple steps in the synaptic vesicle cycle. FM1-43 dye uptake experiments reveal defects in endocytosis and a reduction in the size of the readily releasable and recycling vesicle pools in both TDP-43^{WT} and TDP-43^{G298S} variants. However, upon overexpression of Hsc70, endocytosis is restored specifically only in the disease associated mutant. Genetic interaction approaches reveal the ability of synaptic proteins namely cysteine string protein (CSP), dynamin, clathrin, lap, and auxilin to modulate TDP-43 mediated locomotor dysfunction. The results of these experiments suggest that synaptic vesicle cycling defects resulting from TDP-43 expression occur during early endocytic events at the presynaptic membrane. In addition, overexpression of Hsc70 in the context of TDP-43 mitigates multiple aspects of TDP-43 toxicity including locomotor dysfunction and reduced lifespan. Notably, this rescue is dependent on both the chaperone and membrane bending activities of Hsc70 as evidenced by genetic interactions with Hsc70 ATPase or membrane binding mutants, respectively. Thus, both chaperone and membrane bending activities, both of which contribute to the maintenance of synaptic protein pools, are affected upon TDP-43 overexpression and contribute to ALS phenotypes and toxicity. Our results provide the first evidence for TDP-43 regulating the synaptic vesicle cycle through the translational regulation of its synaptic mRNA targets. Thus, altered ribostasis, a key event in the progression of ALS, contributes to synaptic failure preceding neurodegeneration in ALS pathogenesis.

D184 Glial expression of spen confers a Notch-dependent resistance to paraquat. *Nathalie Davoust*[1], Valérie Goubard[1], Matthieu Quérenet[1], Laurent Seugnet[2], Victor Girard[1], Laurent Pays[3], Serge Nataf[3], Bertrand Mollereau[1]. 1) LBMC, ENS de Lyon, Lyon, FR; 2) CRNL, Waking team, Lyon, FR; 3) CARMEN, HCL, University of Lyon, Lyon, FR.

Parkinson's disease (PD) is the second most prevalent neurodegenerative disease after Alzheimer disease. It is characterized by the selective loss of dopaminergic neurons in the substantia *nigra pars compacta*. Dopaminergic signalling deregulation leads to resting tremor and postural instability. Genetic factors as well as environmental stress such as the use of the pesticide paraquat, have been shown to trigger PD. Although several key molecular players have been identified and characterized in PD models, little is known about the cellular glial mechanisms that may

regulate the survival versus death of dopaminergic neurons.

To identify glial genes involved in dopaminergic neuronal cell death, we combined a candidate gene approach in Drosophila melanogaster and a transcriptomic analysis on the *substantia nigra* from PD patients. Among the *Drosophila* candidate genes, 20 were found to have homologous genes in human that were differentially expressed in PD. And among these 20 genes, we identified *split-ends* (*spen*) has being protector in a chemical model of Parkinson induced by paraquat treatment in *Drosophila*. Spen belongs with spenito to the evolutionary conserved SPEN proteins family. Spen is implicated in multiple cellular processes such as neuronal and glial cell fate or axon guidance during nervous system development and we have recently shown that spen was necessary for interomatidial cells (IOCs) survival during retina development.

We found that brain expression of spen is modulated by paraquat treatment and that flies heterozygous for a loss of function mutation in *spen* exhibit an enhanced vulnerability to paraquat, which indicates a prosurvival function of spen. Importantly, specific depletion of spen in glial cells also renders flies more sensitive to paraquat, while, reversely, over-expression of spen in glial cells has a protective effect. In support of previous reports, a bio-informatics large scale analysis of transcriptomic data indicates that spen and the Notch pathway are tightly interconnected. Using a Notch reporter construct, we indeed demonstrate that spen is required for Notch activity in glial cells. Furthermore, modulation of Notch in glial cells is associated with higher sensitivity to paraquat treatment.

Together, these results suggest that in pharmacological models of PD, spen expression in glial cells is required for a Notch-dependent mechanism of neuronal resistance to oxidative stress. . This finding further supports the importance of glia-mediated neuroprotective pathways under neurodegenerative conditions.

D185 The ecdysone and JAK/STAT pathways regulate proper morphogenetic movement of squamous cells by suppressing Notch-induced Broad. *Dongyu Jia*[1], Allison Jevitt[1], Yoichiro Tamori[2], Yi-Chun Huang[1], Gabriel Calvin[1], Wu-Min Deng[1]. 1) Florida State University, Tallahassee, FL, USA; 2) National Institute of Genetics, Mishima, Japan.

During development, proper formation of epithelial tissues is critical for normal cellular functions, and improper morphological changes could potentially contribute to tumor malignancy. To study epithelial morphogenesis, many animal models have been established, and the *Drosophila* egg chamber is one important system to understand morphogenetic movements. Epithelial cells have three major shapes: cuboidal, columnar and squamous. Here, we focus on squamous cells (SCs, also known as stretched cells), which are restricted at the surface of anterior egg chambers in cuboidal shape at the beginning, then rapidly become flattened in twelve hours to spread over half of the surface. The regulation of this drastic morphological change is still unclear. Our report indicates Broad (Br) interacts with the Notch, ecdysone and JAK/STAT pathways, serving as an important spatiotemporal cue for proper cell differentiation, elongation and movement. The early uniform pattern of Br in the follicular epithelium is directly established by Notch signaling at stages 5/6 during *Drosophila* oogenesis. Ecdysone and JAK/STAT signaling synergize to suppress Br in SCs to de-repress themselves from stage 8 to 10a, which contributes to proper SC stretching. During the process, ecdysone signaling is essential for initiation of SC stretching, while JAK/STAT regulates SCs distribution and cell fate determination. Our findings also shed new light on understanding of squamous cell carcinomas (SCCs), as the SC stretching process is accompanied by loss of epithelial cell marker, and our meta-analysis results implicate that human homologs of ecdysone and JAK/STAT are associated with patient survival outcomes in SCCs.

D186 Selective removal of deletion-bearing mitochondrial DNA in heteroplasmic muscle. *Nikolay Kandul*[1], Ming Guo[2], Bruce Hay[1]. 1) Division of Biology and Biological Engineering, Mail Code 156-29, California Institute of Technology, Pasadena, CA 91125, USA; 2) Departments of Neurology and Pharmacology, Brain Research Institute, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA 90095, USA.

Mitochondrial DNA (mtDNA) often exists in a state of heteroplasmy, in which deleterious mutant mtDNA co-exists in cells along with wildtype mtDNA. Heteroplasmy for pathogenic mutations is common, and high frequencies of mutant mtDNA result in severe maternally inherited syndromes. Inherited and somatically acquired mutations also accumulate over time and contribute to a number of diseases of aging. Reducing heteroplasmy is therefore an important therapeutic goal. Intergenerational selection against mtDNA mutations occurs in germ cells, but whether it also acts in somatic non-diving cells is unclear. To address this question, and provide a system in which genes and drugs that increase mtDNA quality control can be identified, we created a transgene-based model of a lethal heteroplasmic mtDNA deletion ($mtDNA^{\Delta}$) in a non-dividing somatic tissue, the *Drosophila* indirect flight muscle (IFM). A pulse of transcription driven by the *Flightin* promoter drives the expression of two transgenes, which together create $mtDNA^{\Delta}$ directly in IFMs. Quantitative PCR (qPCR) and *in situ* target primed rolling circle amplification show that up to 75% of the total mtDNA in the IFM carries the deletion. High amounts of $mtDNA^{\Delta}$ activate autophagy in the IFM. To determine if mtDNA quality control can be manipulated we overexpressed and knocked down genes in the $mtDNA^{\Delta}$ background, and monitored changes in numbers of $mtDNA^{\Delta}$ molecules. We found that increasing expression of genes involved in autophagy and *PINK1/parkin* pathway, and knocking down *Mitofusin* (*Mfn*) result in a decrease in $mtDNA^{\Delta}$, but not wildtype mtDNA. Conversely, suppressing the autophagy pathway causes a further increase of $mtDNA^{\Delta}$. The selective removal of $mtDNA^{\Delta}$ by *parkin* overexpression is prevented in an autophagy mutant background. In summary, we have developed a system in which the fate of an mtDNA deletion can be monitored *in vivo*, in a tissue important for aging. We also provide evidence that levels of mutant mtDNA can be decreased through manipulation of autophagy/mitophagy, suggesting pharmacological approaches to inhibiting a major cause of age-related decline in cell function.

D187 A Drosophila model for XX Gonadal Dysgenesis. *O. Gerlitz*[1], A. Weinberg-Shukron[2,3], R. Kalifa[1], D. Rekler[1], A. Dreifuss[1], N. Fardian[1], T. Shore[1], P. Renbaum[2,3], E. Levy-Lahad[2,3], D. Zangen[4]. 1) Department of Developmental Biology and Cancer Research, IMRIC, Faculty of Medicine - Hebrew University, Jerusalem, Israel; 2) Medical Genetics Institute, Shaare Zedek Medical Center, Jerusalem, Israel; 3) Hebrew University

Medical School, Jerusalem, Israel; 4) Division of Pediatric Endocrinology, Hadassah Hebrew University Medical Center, Jerusalem, Israel.

Ovarian development and maintenance are poorly understood; however, diseases that affect these processes can offer insights into their underlying mechanisms. XX Gonadal Dysgenesis (XX-GD) is a rare heterogeneous genetic disorder characterized by underdeveloped, dysfunctional ovaries, with a subsequent lack of spontaneous pubertal development, primary amenorrhea, uterine hypoplasia, and hypergonadotropic hypogonadism. Using homozygosity mapping and whole exome sequencing, we identified a missense recessive mutation in Nucleoporin107 (Nup107) in a consanguineous family with multiple females affected by XX-GD (with no other apparent developmental deficits). Nup107 is an essential component of the nuclear pore complex. We use *Drosophila* as a model to study the potential function of Nup107 in human female gonadal dysgenesis. A deletion allele of Nup107 is embryonically lethal in the fly, but can be rescued by exogenously expressing WT Nup107. Transgenic expression of the functionally equivalent *Drosophila* Nup107 missense mutation in flies, while rescuing viability, results in abnormal ovarian development accompanied by an almost complete sterility with a marked reduction in progeny, morphologically aberrant eggshells, disintegrating egg chambers and increased apoptosis, indicating defective oogenesis. RNAi knockdown of Nup107 in somatic gonadal cells causes complete female sterility, whereas males remain fully fertile. Interestingly, this specific RNAi knockdown in follicle cells causes defects in nurse cells and oocytes, both of which are germline cells. In contrast, specific knockdown of Nup107 in the germ line has no apparent effect in either sex. In summary, these results indicate Nup107 as a novel genetic source of ovarian dysgenesis and suggest that nucleoporin defects may play a role in milder and more common conditions such as premature ovarian failure. Future research using this XX-GD *Drosophila* model system will elucidate signaling pathways and new genes involved in both ovarian development and dysgenesis mechanisms.

D188 Mechanism of Ethanol Tolerance: ChIP-seq to identify the signature of ethanol tolerance genes. *Nigel Atkinson*, Alfredo Ghezzi. The University of Texas at Austin, Austin, TX.

Genomic studies often report that a significant fraction of the genome (up to ~30%) changes expression following exposure to ethanol. Unfortunately, responses important for producing alcohol behaviors can be obscured by this surfeit of changes. Functional alcohol tolerance is alcohol-induced alcohol resistance that is not mediated by a change in alcohol metabolism. To help identify changes important for producing functional behavioral tolerance to alcohol, we exploited the fact that two chemically distinct alcohols produce mutual cross tolerance through a related mechanism. This was demonstrated in detail using the Drosophila *slo* gene as a test case. In flies, the capacity to acquire tolerance to either ethanol or benzyl alcohol has been linked to the *slo* gene, which encodes BK-type Ca^{2+}-activated K^{+} channels. Mutations in *slo* block the acquisition of tolerance, sedation with either drug induces *slo* expression, and *slo* induction has been shown to phenocopy tolerance. A survey of the alcohol-induced changes in histone modification and transcription factor binding across the *slo* transcriptional control region proved to be an effective way to identify DNA regulatory elements that mediated the alcohol response. Based on the success of this approach, we performed a genomic survey to identify all genes and regions that respond similarly to both benzyl alcohol and ethanol. This technique identified a gene network, shown to play important roles in this alcohol response (tested by mutation, RNAi, or transgenic mis-expression). We also developed profiles for alcohol-induced histone H4 acetylation patterns and CREB-binding patterns across the *slo* promoter region. These profiles were then used in a ChIP-Seq genomic survey to find other genes with similar patterns. By doing so we have developed a refined profile of one class of alcohol-regulated gene.

D189 A Drosophila Model of Essential Tremor. *Lorraine N. Clark*[1,2], Ronald Arias[2], Philip Smith[3], Krasimira Tsaneva-Atanasova[4], James Hodge[3], Brian McCabe[5], Elan Louis[6]. 1) Taub Institute for Research on Alzheimer's Disease and the Aging Brain, Columbia University, New York, NY, USA; 2) Department of Pathology and Cell Biology, Columbia University, New York, NY, USA; 3) School of Physiology, Pharmacology and Neuroscience, University of Bristol, Bristol, UK; 4) Department of Mathematics, University of Exeter, Exeter, UK; 5) Brain Mind Institute, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland; 6) Departments of Neurology and Chronic Disease Epidemiology, Yale School of Medicine and Yale School of Public Health, Yale University, New Haven, CT, USA.

Objective: To generate and characterize a *Drosophila* Model of *KCNS2* associated Essential Tremor (ET).

Background: ET is one of the most common neurological diseases, with an estimated 7 million affected individuals in the US. The most characteristic clinical feature of ET is a kinetic tremor in the hands or arms. As the disease progresses, tremor becomes more severe and more anatomically widespread (e.g., head, trunk). Recently, we identified a mutation (p.Asp379Glu) located in the pore domain of a potassium channel alpha subunit, *KCNS2*, in an early onset family with autosomal dominant ET. KCNS2 is highly and selectively expressed in the brain and modulates the activity of the *KV2.1* (*Shab*) and *KV2.2* (*Shab related*) channels.

Methods: The pBID-UAS *Drosophila* vector (McCabe lab) was used to express human normal *KCNS2* and mutant *KCNS2* in *Drosophila*. Transgenic flies were crossed to a number of well-characterized lines that express and drive expression in tissue- and cell-type-specific patterns (e.g. panneuronally or motor neurons). To determine the effects of human wildtype and mutant *KCNS2* on adult clock neuron activity, electrophysiology recordings were performed by using whole cell voltage-clamp. Using a Shab specific toxin we were able to isolate the Shab current which is a voltage-senstive non-inactivating potassium current. Expression of human wildtype *KCNS2* caused the Shab current to become an inactivating current activating at more hyperpolarised currents. Expression of human mutant *KCNS2* caused both phenotypes but to a greater extent. In addition to neuronal degeneration we also investigated the behavioral manifestations of nervous system dysfunction in the transgenic flies.

Results: Here we express human normal and mutant (p.Asp379Glu) forms of *KCNS2* in *Drosophila* (panneuronally and restricted to subsets of neurons) and produce adult onset leg shaking, abdomen pulsations and shuddering under ether anesthetization in addition to bilateral wing elevation indicative of loss of neurons during aging. Electrophysiological recordings show expression of human *KCNS2* (particularly the mutant form) switched Shab into an inactivating current which would be expected to contribute to neuronal hyperexcitability.

Conclusion: Our *Drosophila* model recapitulates some of the features of ET, and can now be used to advance our understanding of disease pathogenesis and to identify pathways that can be targeted for pharmaco-therapeutics for ET.

D190 Modulation of bursting kinetics generates specific gene expression rates in the early embryo. *Shawn Little*, Eric Wieschaus, Thomas Gregor. Princeton University, Princeton, NJ.

Precise control of gene expression is a hallmark of early development. To understand how random molecular interactions generate reproducible gene expression patterns, we have developed methods for absolute quantification of transcription rates. We examine gene expression dynamics at the level of individual gene loci using a combination of single molecule counting, live transcription imaging, and computer simulations. Several genes found in broad domains of the blastoderm stage embryo are expressed at equivalent rates within their respective domains of fastest accumulation. However, this fastest, or maximum, expression rate does not result from constitutive, fully active expression. Instead, transcription switches between expressing and non-expressing states during interphase, a phenomenon referred to as "bursting." Our analysis suggests that a single rate-limiting molecular interaction, occurring at random, determines bursting kinetics. We find that the on- and off-rates that determine bursting kinetics are finely tuned across genes in order to generate equivalent expression rates within domains of highest activity. We also find that a minimal promoter/enhancer from the gene *hunchback* is sufficient to confer bursting kinetics that are identical to those observed for the endogenous *hunchback* gene in the domain of highest activity. This suggests that multiple enhancers are not required to determine correct transcription dynamics.

D191 A fully synthetic transcriptional enhancer platform for study of regulatory protein function in a multicellular eukaryote. *J. Crocker*, D. Stern. HHMI Janelia, Ashburn, VA.

The complex spatial and temporal patterns of gene expression during development of multicellular organisms are determined by the binding of transcription factor proteins to regions of genomic DNA called enhancers. Traditionally, tests of the *in vivo* functions of transcription factors have been performed using modified native enhancers. These native enhancers have provided great insight, but can also yield unpredictable results, presumably because they also encode sites of unknown function. A synthetic, transcriptionally silent enhancer platform may allow cleaner tests of regulatory protein function, but, to date, attempts to build a synthetic enhancer in a multicellular eukaryote—by combining binding sites for transcriptional activators and repressors—have largely failed to produce predictable patterns of gene expression. Here we report construction of a fully synthetic transcriptional platform in *Drosophila* consisting of an engineered transcriptional activator and an artificial enhancer platform. We found that binding sites for a transcriptional activator are not sufficient to drive transcription. Instead, binding sites for a transcription factor that makes DNA accessible are required together with binding sites for transcriptional activators to produce a functional enhancer. Only in this context can changes in the number of activator binding sites mediate quantitative control of transcription. Our synthetic system provides a platform for testing models of transcriptional regulation and will provide an improved understanding of how natural networks function.

D192 Developmental Regulomes – Resolving Enhancer-Protein Interactions with Temporal and Tissue-Specificity. *Robert P. Zinzen*[1], Sabrina Krueger[1], Djordje Vasiljevic[2], Matthias Selbach[2], Robert P. Zinzen[1]. 1) Berlin Institute of Medical Systems Biology (BIMSB-MDC), Berlin, Germany; 2) Max Delbruck Centre for Molecular Medicine (MDC), Berlin, Germany.

Tightly coordinated control of gene expression is essential, especially in development. *Cis*-regulatory elements (CRMs) like enhancers act as information integration hubs to drive and regulate spatio-temporal gene expression by interpreting the specific cellular environment (transcription factor (TF) availability, chromatin state, etc.) to translate the available regulatory information into transcriptional responses.

While it is possible to identify CRMs globally, we are largely unable to explain the exact spatio-temporal activities that individual identified enhancers actually drive when tested *in vivo over the course of development*. Our knowledge of the suit of regulatory interactions that converge on individual enhancers is all too often incomplete. In order to accurately predict and model enhancer activity *in vivo*, identification of these inputs remains a crucial challenge.

We have developed a method that allows for the biochemical isolation of defined regulatory elements from whole animals to high purities. We show that protein:DNA interactions remain stable during purification and that mass spectrometry can identify specific CRM:protein interactions, including TFs, as well as chromatin modulators and local nucleosome components. The major advantage of our approach is that using the genetic accessibility of *Drosophila,* we are not limited to querying such interactions at developmental stages, but we can do so in a tissue- and cell type-specific manner. For the first time, we are able to extract specific DNA elements from embryos and identify their tissue-specific regulatory interactions (i.e. their '*regulomes')* to ask what renders an enhancer active in one tissue, but inactive in another, how these interactions change over the course of development, and how they depend on activity state?

Deploying this method to query enhancer:protein interactions of neurectodermal enhancers has revealed dozens of potential regulators, known and novel, which we are now being tested for their global roles in early nervous system patterning.

The method presented here is broadly applicable to the identification of specific DNA:protein interactions *in vivo* with temporal and tissue-specificity and should be expandable for the identification of other potential regulators including lncRNAs and local genome architecture.

D193 Application of ChIP-nexus to map transcription factors during development. *Robin Fropf*[1], Qiye He[2], Jeff Johnston[1], Julia Zeitlinger[1,3]. 1) Stowers Institute for Medical Research, Kansas City, MO; 2) Zhejiang University, Hangzhou, China; 3) University of Kansas Medical Center, Kansas City, MO.

A mechanistic understanding of how cis-regulatory sequences are decoded relies on high-resolution transcription factor binding footprints.

Since the function of enhancers can only be assayed in the cell type in which they are active, this task ultimately requires the analysis of a wide variety of different cell types, many of which are hard to isolate in large numbers. To map transcription factor binding in specific cell types *in vivo*, it is therefore vital to improve the efficiency of current ChIP-seq protocols, ideally also with increased resolution. Nucleotide resolution can be achieved through a ChIP-exo protocol, which uses a lambda exonuclease digestion step to precisely locate the boundary at which the cross-linked protein is bound to DNA. To apply ChIP-exo to *Drosophila* embryos, we recently developed a new technique termed ChIP-nexus (ChIP with nucleotide resolution through exonuclease, unique barcode and single ligation). ChIP-nexus introduces a novel library preparation protocol that relies on self-circularization and thus improves the efficiency by which DNA fragments are incorporated into the library. ChIP-nexus outperforms existing ChIP protocols in resolution and specificity and pinpoints relevant binding sites within enhancers containing multiple binding motifs. We are currently working on additional modifications to the protocol to further increase the efficiency, allowing lower amounts of starting material. This will enable the precise mapping of transcription factor binding in cell types of low abundance, facilitating the application of ChIP-seq to samples that were previously not accessible to such an analysis..

D194 Natural variation in binding site affinity controls stochastic gene expression in the fly eye. *C. Anderson*[1], C. Zhou[1], I. Reiss[1], A. Cho[1], H. Siddiqi[1], B. Mormann[2], C. Avelis[1], E. Roberts[1], J. Taylor[1], D. Vasiliauskas[3], R. Johnston[1]. 1) Johns Hopkins University, Baltimore, MD; 2) New York University, New York, NY; 3) Université Paris Diderot, Paris, France.

Stochastic mechanisms are critical to diversify cell fates during development. How the proportions of randomly determined cell fates is controlled is poorly understood. The stochastic on/off expression of the transcription factor Spineless (Ss) in R7 photoreceptors determines the patterning of two subtypes in the fly eye. Our studies of natural variation revealed a single nucleotide polymorphism (SNP) in a non-coding DNA element in the *ss* gene locus that lowers the percentage of Ss on cells ("*low ss SNP*"). This SNP lies within a binding site for the zinc finger transcriptional repressor Klumpfuss (Klu) and increases Klu binding affinity. Klu acts in R7s to lower the ratio of Ss on to off cells: loss of *klu* function causes more R7s to express Ss whereas increasing Klu levels causes a decrease in the number of Ss-expressing R7s. Thus, the levels of Klu protein are converted into a ratio of Ss on/off cells. Our data suggest that stochastic on/off gene expression is controlled by threshold levels of *trans* factors bound to low affinity sites.

D195 Towards a 4D understanding of chromatin architecture and transcriptional regulation. *H. Chen*[1], M. Fujioka[2], T. Gregor[1]. 1) Princeton University, Princeton, NJ; 2) Thomas Jefferson University, Philadelphia, PA.

We use Drosophila embryo as a model to study the dynamic properties of 3D genome organization and the functional significance of chromatin architecture on the regulation of gene transcription. Using a combination of genetics, genome editing and live imaging, we are able to mark specific genes with fluorescent markers and trace the movement of individual loci. Particularly, by simultaneously labeling promoter activity and the position of enhancers, we are able to measure kinetic parameters (e.g. looping probability, dwell time and dissociation constants) for long-range promoter-enhancer interactions. Furthermore, by synthetically tuning the promoter-enhancer distance and the insulator elements that mediate the interactions, we are able to investigate the mechanistic details of chromatin looping and enhancer searching through physical polymer modeling.

D196 Zelda pioneers early enhancers during genome activation. *C. A. Rushlow*[1], Y. Sun[1], C. Y. Nien[1], K. Chen[2], J. Chen[1], H. Crimmins[1], J. Johnston[2], N. Kirov[1], J. Zeitlinger[2]. 1) New York Univ, New York, NY; 2) Stowers Institute for Medical Research.

The Zn finger transcription factor Zelda serves as a major hub in the early gene network. Zelda binds to CAGGTAG motifs in enhancers of early-expressed genes, which can be categorized into two types. Class I genes are uniformly expressed like Zelda, and absent in *zelda*$^-$ mutants, suggesting direct activation by Zelda. Class II genes are spatially-restricted patterning genes, which are delayed and sporadic in *zelda*$^-$ but nevertheless expressed, as they are primarily regulated by patterning factors such as Dorsal and Bicoid, suggesting a timing and potentiating role for Zelda. What determines whether Zelda will be a direct activator or a potentiator? We will discuss differences in RNA Polymerase II pausing, promoter motifs, and transcription factor binding that distinguish Zelda's two different roles. In addition, we will present evidence that Zelda's potentiating role is based on its ability to act like a pioneer factor and bind its motifs in nucleosomes. We discuss our model of how Zelda "scouts out" regions of high nucleosome occupancy, then upon binding to CAGGTAG motifs, displaces nucleosomes just enough for other factors to access the genome. In this way Zelda imparts "enhancer competence" globally during genome activation.

D197 Highly accurate prediction of early anterior-posterior enhancer sequences from ChIP-seq data. *H. Arbel*[1], P. Bickel[1], S. Celniker[2], M. Biggin[2], J. B. Brown[1,2]. 1) University of California, Berkeley, Berkeley, CA; 2) Lawrence Berkeley National Laboratory, Berkeley, CA.

In animals, definitive epigenetic signatures of enhancer elements have been challenging to identify– the best prediction tools offer weak positive predictive power at genome-scales and are not accurate enough to conduct in silico enhancer annotation. In the early Drosophila embryo, a small cohort of ~40 transcription factors drive body patterning. Hence, fly development offers a simplified model system in which to study the relationship between transcription factor binding and tissue-specific enhancer activity. We studied the DNA binding patterns for 22 of these factors, as well as chromatin marks during embryonic stages 4 and 5. We applied supervised machine learning to identify enhancer sequences active during embryogenesis using a test set of over 7000 whole-embryo in situ imaging experiments. We find that we have nearly perfect predictive accuracy for early anterior-posterior (AP) enhancer sequences (>97% predictive accuracy, suitable for whole-genome scans), while dorsal-ventral (DV) and other classes of enhancers are far more challenging to predict. Further examination of "false positives" identified by our methods reveals manual annotation errors in the labeling of in situ experiments – our actual correct classification rate is likely higher than reported here. Well-predicted enhancers admit a unique epigenetic signature involving interactions between both AP and DV

transcription factors. Our model identifies nonlinear interactions between cohorts of transcription factors, suggesting the presence of combinatorial activation rules. Using a whole genome scan, we predict that around 1.6% of 1kb windows in the genome are likely AP enhancers (recovering 98% of known enhancers from our training and test data). For the first time, we demonstrate a sufficiently accurate enhancer prediction algorithm to enable the near-comprehensive discovery of a subclass of enhancer sequences.

D198 ESCRTs and intraluminal vesicles play novel roles in controlling exosome heterogeneity, late endosomal acidification and regulated secretion. *Benjamin Kroeger*, Shih-Jung Fan, Felix Castellanos, Sumeth Perera, Irina Stefana, Siamak Redhai, Mark Wainwright, Carina Gandy, Deborah Goberdhan, Clive Wilson. Dept. of Physiology, Anatomy & Genetics, University of Oxford, Oxford, UK.

The appropriate functioning of the endosomal system is an essential aspect of cell biology, intimately linked to cell-cell signalling and growth regulation. One component of this system, the late endosomal multivesicular body (MVB), is characterised by its many intraluminal vesicles (ILVs), whose formation is dependent on the evolutionarily-conserved Endosomal Sorting Complexes Required for Transport (ESCRT) 0-III. Although some functions of ILVs are yet to be fully elucidated, MVBs can fuse to the plasma membrane, releasing their ILVs as exosomes (nano-sized extracellular vesicles that transmit multiple signals between cells). ILVs are also thought to prevent excessive receptor-ligand mediated signalling and can be degraded following MVB fusion to lysosomes. We are studying the roles of ILVs *in vivo* in secondary cells of the *Drosophila* male accessory gland and aim to translate these findings into human systems. These cells have extraordinarily large (5-10 µm diameter) endosomes, allowing us to readily visualise their diversity, abundance and intraluminal contents. We utilise a combination of molecular genetic approaches and advanced microscopy techniques, including super-resolution 3D structured illumination microscopy (SIM), electron and time-lapse wide-field microscopy. Using 3D-SIM we visualise and resolve ILV populations in living cells for the first time. We observe that ILVs carrying exosome markers are formed within the late endosomal MVBs, as expected, but also within recycling endosomes. These two types of ILV are loaded with different cargos, and secreted via different signalling-dependent mechanisms. We provide evidence that ESCRT complexes localise to and are required for the biogenesis of ILVs in both late and recycling endosomes. We show that human cancer cells also form at least two exosome subtypes in the equivalent compartments, suggesting these cell biological processes are evolutionarily conserved. Functional characterisation reveals at least two previously unsuspected roles for the different ILV populations. We show that late endosomal ILVs carry the v-ATPase proton pump, which sets up acidic microdomains around their exterior, which appears to be required for acidification of this compartment. In addition, ILVs in recycling endosomes play an essential role in the maturation of the dense-core compartments involved in regulated secretion. Our studies therefore reveal multiple new sub-compartmental functions for ILVs and ESCRTs, and provide key evidence to help explain the diversity of exosomes and their biological functions.

D199 Mitophagy is dispensable for axonal maintenance during normal aging in *Drosophila*. *Y. Fang*[1], X. Cao[1], H. Wang[1], Q. Wang[1], N. M. Bonini[2], Y. Fang[1]. 1) IRCBC, SIOC, Chinese Academy of Sciences, Shanghai, China; 2) Dept of Biology, UPenn, Philadelphia.

Healthy mitochondria are required for maintaining neuronal integrity and function. Mitochondria undergo dynamic fission-fusion and damaged mitochondria are cleared by autophagy (termed as mitophagy). Recently, there have been debates on whether mitophagy occurs locally in axons or whether damaged mitochondria need to be transported to the neuronal soma for lysosome-mediated turnover (Cai et al., 2012; Ashrafi et al., 2014; Maday and Holzbaur, 2014). To address this question, we have developed a *Drosophila* wing nerve model, which allows us to label axons and mitochondria by different fluorescent proteins to study their changes during aging *in vivo*.

We found mitochondria in axons were significantly shorter in aged flies, suggesting that mitochondria become fragmented during aging. Alternatively, it may be due to reduced mitophagy in aged axons. We hence studied the consequence of manipulating key mitophagy genes *Pink1* and *Parkin* in axons. To our great surprise, unlike in muscles where the $Pink1^{B9}$ null mutation caused severe mitochondria abnormality and muscle degeneration (Clark et al., 2006; Park et al., 2006), $Pink1^{B9}$ flies showed normal mitochondria morphology, size and density in neurons, and did not cause spontaneous axon degeneration. This result suggests that local axonal mitophagy might not be an essential mechanism in maintaining neural integrity during aging. Consistently, we found that co-localization of mitochondria and autophagosomes almost exclusively occurred in the neuronal soma and was essentially not observed in axons, even in aged flies. The co-localization occurrence in soma did not decrease with age, suggesting a constant mitophagy level in neurons during aging. Co-localization of axonal mitochondria and autophagosomes *in vivo* were observed only after axotomy in the injured wing nerve. This is consistent with previous *in vitro* studies where extreme insults such as H_2O_2 or CCCP were used to induce mitophagy in cultured neurites.

Next, we overexpressed *Pink1* or *Parkin* to see if promoting mitophagy mitigated age-associated accumulation of damaged mitochondria in neurons. Unexpectedly, however, both flies showed increase in fragmented mitochondria and severe spontaneous axon degeneration. Upregulation of mitochondria fusion genes could fully rescue the axonal phenotypes of *Parkin* OE. Together, our results indicate that mitophagy is dispensable for axonal integrity and we have additional evidence suggesting that fission-fusion plays a major role in keeping healthy and functional mitochondria in axons during normal aging.

D200 Endosomal Microautophagy: a genetic model in *Drosophila*. *A. Mukherjee*, B. Patel, H. Koga, A. M. Cuervo, A. Jenny. Albert Einstein College of Medicine, Bronx, NY.

Autophagy is an essential pathway that maintains the energy balance of cells by lysosomal degradation and recycling of dysfunctional proteins and organellar components. Importantly, autophagy also provides nutrients including amino acids and lipids to cells under stress conditions and is thus essential for energy balance. As such, autophagy counteracts various human diseases (related to liver, kidney and the nervous system), and its reduction leads to aging like phenotypes. Macroautophagy (MA), the best studied form of autophagy to this date, selectively degrades organelles or aggregated proteins, but selective degradation of single proteins has only been described for Chaperone-

mediated autophagy (CMA) and endosomal Microautophagy (eMI). These two autophagic pathways, described to date only in mammals, are specific for cytosolic proteins containing KFERQ-related targeting motifs. However, CMA and eMI have only been described in mammals and thus lack a model in a genetically easily tractable organism.

Using transgenic flies expressing a KFERQ-tagged fluorescent biosensor, we have identified and functionally characterized an eMI-like pathway in *Drosophila melanogaster*. Our functional *in vivo* studies in fly fat body (functionally equivalent to the mammalian liver) reveal that the biosensor forms puncta in response to prolonged starvation and co-localizes with lysosomes/late endosomes in a KFERQ- and Hsc70-dependent manner. Furthermore, fly eMI requires endosomal multivesicular body formation mediated by ESCRT complex components. Importantly, induction of *Drosophila* eMI requires longer starvation than the induction of MA and is independent of the critical MA genes *atg5*, *atg7*, and *atg12*.

Tor signaling represses MA by inactivating the Atg1/Atg13 complex. Interestingly, inhibition of Tor signaling is also sufficient to induce eMI in flies under nutrient rich conditions, and, as eMI in *Drosophila* also requires *atg1* and *atg13*, our data suggest that these genes may have a novel, additional role in regulating eMI in flies.

Overall, our data provide the evidence for a novel, starvation inducible catabolic process resembling endosomal Microautophagy in a non-mammalian species *in vivo*. It is tempting to speculate that *Drosophila* eMI is an older form of selective autophagy that fulfills functions that in mammals are shared between eMI (likely the constitutive form) and CMA (the starvation-induced variant).

D201 Mechanisms of rapid, membrane-dependent furrow formation in the early Drosophila embryo. *J. Todd Blankenship*, Lauren Mavor, Yi Xie, Ryan Holly, Hui Miao. University of Denver, Denver, CO.

One of the primary events that must occur repeatedly throughout a complex animal's lifetime is the ingression of a plasma membrane furrow. Furrow formation and ingression are obligate parts of cell division, and drive the physical separation of one cell into two cells. Furrow formation in early syncytial Drosophila embryos is exceptionally rapid, with hundreds of furrows forming synchronously in as little as 4 minutes. Here, we use 4D imaging to identify furrow formation, stabilization, and regression periods, and identify a rapid, membrane-dependent pathway that is essential for plasma membrane furrow formation *in vivo*. While Myosin II function is thought to provide the ingression force for cytokinetic furrows, the role of membrane trafficking pathways in guiding furrow formation is less clear. We demonstrate that a membrane trafficking pathway centered on RalA, Rab8, Rab11, and the exocyst complex is required for fast furrow ingression in the early fly embryo. This trafficking pathway is absolutely required for furrow formation and initiation, and genomic instability occurs when its function is disrupted. We show that Rab8 vesicular intermediates direct the delivery of internal cytoplasmic Rab11 membrane pools to the cell surface through a RalA/exocyst targeting function. In contrast, Myosin II activity is not required for furrow ingression, but is needed to enforce furrow uniformity. These studies identify a pathway, which stretches from Rab11 to Rab8 to RalA and the exocyst complex that mediates rapid furrow formation in early Drosophila embryos.

D202 The Voltage Gated Chloride Channels CLC-b and CLC-c play critical roles in lifespan and cell viability respectively. *R. E. Burke*, S. Judd-Mole. Monash University, Melbourne, Victoria, AU.

Mammalian members of the Voltage Gated Chloride Channel family of Cl^-/H^+ exchanger proteins (CLC-3 to 7) are thought to play a range of cellular roles in transepithelial transport, endocytosis, cell volume regulation and the acidification of intracellular organelles. Mutations of these proteins in mice or humans have been shown to cause disease symptoms such as neuronal ceroid lipofuscinosis (CLC-6 and 7), osteopetrosis (CLC-7), Dents disease (CLC-5) and lysosomal storage disorders (CLC-3).

Drosophila has fewer CLC proteins, with CLC-c homologous to mammalian CLC-3, 4 and 5 and CLC-b homologous to CLC-6 and 7. As such it represents an excellent system in which to study the precise cellular role of each class of chloride channel. We have characterised the function of CLC-b and CLC-c.

A CLC-b:GFP fusion protein was found to localize to lysosomes. *ClC-b* null homozygotes are viable but exhibit a dramatic reduction in both lifespan and locomoter activity, plus a mild pigmentation defect. These phenotypes are reminsicent of the symptoms of neuronal ceroid lipofuscinoses caused by disruption of CLC-6 or 7 and may represent a defect in lysosomal acidification leading to lysosomal storage disorder-like pathologies. The *ClC-b* mutant flies are therefore a promising model for studying the molecular mechanism underlying such disorders.

A CLC-c:GFP fusion protein was shown to localize both to the apical plasma membrane and to endolysosomal vesicles. *ClC-c* null mutant homozygotes die in early larval development indicating that, unlike any of its three mammalian homologues, *ClC-c* is essential for viability. Mosaic analysis demonstrated that *ClC-c* homozygous mutant cells have a survival defect and are out-competed by surrounding wild type cells in the larval wing imaginal disc. Prior to undergoing apoptosis, these *ClC-c* mutant cells exhibit an increase in LysoTracker staining that is independent of autophagy. Therefore unlike proposed roles for its mammalian homologues in lysosomal acidification, CLC-c is more likely to be required either in the recycling of endosomes back to the plasma membrane, or the transition of late endosomes to lysosomes. A block in either function may result in an increase in acidified late endosomes, leading to the elevated LysosTracker signal observed.

Our initial charaterization of CLC-b and CLC-c function paves the way to an in-depth investigation of the molecular pathology underlying disorders such as Dent's disease and neuronal ceroid lipofucinoses, which could then be used as a platform for the identification of drugs able to restore function to defective chloride channel proteins.

D203 A screen for systemic growth regulators reveals *hobbit*, a novel and conserved regulator of insulin secretion. *Sarah Neuman*, Jessica Smoko, Arash Bashirullah. University of Wisconsin-Madison, Madison, WI.

Insulin signaling plays a central role in the regulation of systemic growth in *Drosophila*, and therefore is critical in the determination of final

body size. However, the mechanisms regulating insulin secretion remain poorly understood. In a forward genetic screen for mutants with reduced body size, we identified 5 alleles of a novel gene, which we named *hobbit*. *Hobbit* is highly conserved from yeast to humans, but no function has been assigned to the protein in any organism. Our results demonstrate that *hobbit* has a non-cell autonomous effect on growth, indicating that the small body size of the mutants is due to a systemic growth defect. We found that *hobbit* mutants exhibit dramatic defects in insulin secretion, and this defect is directly responsible for the small body size of the mutant animals. Importantly, these insulin secretion defects can be rescued by expressing Hobbit specifically in tissues required for insulin secretion. Furthermore, we demonstrate that expression of the human ortholog of *hobbit* is sufficient to rescue the fly mutant, suggesting that the function of *hobbit* in insulin secretion is conserved. We are currently focused on analyzing the mechanism by which *hobbit* regulates secretion of insulin, and our results indicate that *hobbit* is required for a novel step in the regulated exocytosis pathway. Overall, we have identified a novel regulator of exocytosis that is required for insulin secretion and the control of systemic growth during development.

D204 Spastic paraplegia proteins help model the axonal endoplasmic reticulum network in *Drosophila*. *Cahir J. O'Kane*[1], Belgin Yalçin[1], Martin Stofanko[1], Niamh C. O'Sullivan[1], Lu Zhao[1], Annika Roost[1], Zi Han Kang[1], Matthew R. Thomas[1], Sophie Zaessinger[1], Olivier Blard[1], Valentina Baena[2], Mark Terasaki[2]. 1) University of Cambridge, Cambridge, GB; 2) University of Connecticut Health Centre, Farmington, CT.

The length of motor axons entails significant engineering for their formation and maintenance. Failures of this are seen in the Hereditary Spastic Paraplegias (HSPs), with lower limb weakness, and degeneration of longer upper motor axons. To date over 60 causative Spastic Paraplegia Genes (SPGs) are known. Several encode endoplasmic reticulum membrane proteins, with intramembrane hairpins that curve and model ER membrane, suggesting the axonal ER network as an important component to maintain function and integrity of long axons.

We have explored this model in Drosophila by testing for abnormalities of the axonal ER network in Drosophila that lack SPG-encoded intramembrane hairpin proteins. We have focused on two of these protein families, reticulons and REEPs, which are together required for formation of most tubular ER in yeast. We have developed axonal ER markers in Drosophila, and mutants that lack one or more members of these protein families. We see widespread if not ubiquitous occurrence of tubular ER in axons, and a range of loss-of-function phenotypes, and partial redundancy of gene function. Loss of either reticulon, or one REEP gene, leads to partial loss of ER from distal but not proximal axons, recapitulating the susceptibility of longer distal axons in the human diseases. Loss of multiple genes can lead to phenotypes consistent with loss of ER membrane curvature, including some loss of continuity of the ER network in axons.

We therefore propose a role for SPG genes in establishing or maintaining the axonal ER network, and a role for ER continuity in axons, which could account for the preferential susceptibility of longer axons to HSP.

D205 Asymmetric Endoplasmic Reticulum partitioning is dependent on Jagunal in the early Drosophila embryo. *B. Riggs*, A. Eritano, A. Altamirano, S. Beyeler. San Francisco State University, San Francisco, CA.

Cell division is classically described as the division of genetic material and the corresponding reorganization of the cytoskeleton. However, the mechanisms by which organelles are segregated into daughter cells remain poorly understood. In investigating the molecular mechanisms underlying partitioning of the Endoplasmic Reticulum (ER), we sought to quantify ER segregation during cell division in the early gastrulating *Drosophila* embryo. Interestingly, we found, that at the start of gastrulation (14^{th} mitotic division), the ER divides asymmetrically in a population of asynchronously dividing epithelial cells at the anterior end of the embryo. Asymmetric division of the ER is restricted to this anterior population of cells, as other cellular domains during the 14^{th} mitosis display a symmetrical division. Furthermore, we found this asymmetric division of the ER dependent on the highly conserved membrane protein Jagunal. RNA inhibition of Jagunal, just prior to the start of gastrulation, disrupts this asymmetric division of the ER. This anterior cell population will eventually give rise to the asymmetrically dividing procephalic neuroectoderm, suggesting a link between ER distribution and the establishment of cell fate.

D206 Inhibiting lipid transfer between neurons and glia by modulating lactate levels delays neurodegeneration. *Lucy Liu*[1], Hugo Bellen[1,2]. 1) Baylor College of Medicine, Houston, TX; 2) Howard Hughes Medical Institute, Houston, TX.

High levels of Reactive oxygen species (ROS) and the presence of mitochondrial defects in neurons are implicated in neurodegeneration. Previously, we have shown that lipid droplets (LD) accumulate in glia prior to neurodegeneration due to high levels of ROS activating neuronal C-Jun N-terminal Kinase (JNK) and Sterol Regulatory Element Binding Protein (SREBP). Activating lipogenesis in neurons alone will cause glial LD accumulation, suggesting that lipids are transferred from neurons to glia. However, the mechanism by which these lipids transfer is unexplored. Through a candidate gene screen designed to isolate genes involved in lipid transfer, we isolated monocarboxylate transporters (MCTs) along with fatty acid transporters and apolipoproteins, all of which are critical for eventual lipid transfer and glial LD accumulation. Furthermore, we have established a potential mechanism by which the lipids are transferred from the neuron to the glia. The pathway starts with the observation that glial cells secrete lactate via MCTS. This lactate is taken up by the neuronal MCTs. The neuron converts lactate to pyruvate to be used as an energy source in the TCA cycle. However, in the disease state, excess energy is diverted into the lipid synthesis pathway and lipogenesis is upregulated due to elevated SREBP and Acetyl coA carboxylase (ACC). The lipids are then transfer from the neuron via fatty acid transport protein (FATP) and carried by extracellular apolipoproteins to the glia. Importantly, blocking lactate transfer either genetically or pharmacologically will inhibit glial LD accumulation and delays cell death in mutant flies and in a murine neuronal-glial co-culture model. Similarly, removing FATP or the apolipoproteins also reduces LD accumulation. In brief, we are unraveling a mechanism that leads to lipid production, lipid transfer and lipid accumulation in the nervous system that has not yet been documented and that promotes neurodegeneration.

D207 Mitochondrial-nuclear incompatibility during oogenesis causes embryonic lethality. *C. Zhang*[1], K. Montooth[2], B. Calvi[1]. 1) Indiana University, Bloomington, IN; 2) University of Nebraska-Lincoln,Lincoln, NE.

Female reproduction is strongly affected by age, nutrition and metabolic homeostasis. There is increasing evidence that age-related female infertility is associated with reduced mitochondrial function. Although mitochondria have their own genomes, ~1500 nuclear-encoded gene products are transported into mitochondria and are required for mitochondrial function. Mutations in either these nuclear or mitochondria-encoded genes are known causes of a number of human mitochondrial diseases. It is less clear, however, whether mitochondrial diseases can result from specific incompatibilities between the nuclear and mitochondrial genomes.

Here, we use a previously established mito-nuclear incompatible Drosophila model to investigate its impact on female fertility. The (simw501); OreR mito-nuclear genotype carries mitochondria from D. simulans in a D. melanogaster OreR nuclear background. It was previously shown that a mito-nuclear incompatibility in this strain results in developmental delay, defective muscle function, and reduced oxidative phosphorylation. The basis for this mito-nuclear incompatibility are polymorphisms in the mitochondria-encoded tyrosyl-tRNA and the nuclear-encoded mitochondrial tyrosyl-tRNA synthetase (Aats-tyr-m or Aatm) genes. We now show that this incompatible (simw501); OreR strain has severe oogenesis defects, including death of germline stem cells and cystocytes, and egg chamber degeneration, which together result in reduced egg production. In addition, these strains have a strict temperature-sensitive maternal-effect embryonic lethality that is completely dependent on the developmental temperature of the mother. The temperature sensitive period in the mother is during late 3rd instar / pupation, and is not reversible by shifting the temperature of adult females. These last observations suggest that continued embryonic lethality results from some type of maternal metabolic memory. Our findings show that maternal mito-nuclear incompatibility has severe consequences for oogenesis and embryonic survival. More broadly, our results raise the possibility that mito-nuclear incompatibility could cause female infertility in humans.

D208 *dSod1* knock-in mutations cause ALS-like phenotypes in *Drosophila*. *A. H. Held*, A. Sahin, P. Major, D. Lipscombe, R. A. Reenan, K. A. Wharton. Brown University, Providence, RI.

Amyotrophic Lateral Sclerosis (ALS) is the most common adult onset motor neuron disease. ALS patients experience a rapid loss of motor function over the course of 2-5 years due to motor neuron death and neuromuscular junction (NMJ) deterioration. Approximately 20% of familial ALS cases are caused by mutations in superoxide dismutase-1 (hSOD1), and overexpression of mutant hSOD1 alleles has been used to model ALS in *Drosophila, C. elegans,* zebrafish, and mice. Overexpression of mutant hSOD1 in mice causes early lethality, progressive loss of motor function, NMJ deterioration, and motor neuron death, but overexpression of WT hSOD1 mimics several of these ALS-like phenotypes as well. The fact that WT hSOD1 overexpression can cause motor neuron death and impair motor function raises the possibility that high levels of SOD1 via overexpression may not accurately recapitulate the pathogenesis of ALS. To model ALS, the Reenan lab used homologous recombination to place synonymous disease causing dSod1 alleles under the control of the endogenous dSod1 promoter. Our characterization demonstrates that two mutations, $dSod1^{G85R}$ and $dSod1^{H71Y}$, cause 1) early lethality, 2) a loss of neuromuscular junction integrity, 3) electrophysiological defects and 4) a progressive loss of motor function. 1) Both alleles show profound lethality at eclosion with 100% of $dSod1^{G85R}$ and 75% of $dSod1^{H71Y}$ failing to fully eclose. The remaining 25% of $dSod1^{H71Y}$ flies that eclose show a reduced lifespan with a median survival of 14 days and a reduction in climbing ability as they age. 2) To identify why these dSod1 mutants fail to eclose, we examined nerve integrity in legs and the abdominal NMJ that both play an important function in successful eclosion. We found that $dSod1^{G85R}$ and $dSod1^{H71Y}$ mutants have disrupted leg nerve integrity and NMJ structure. 3) Furthermore, electrophysiological recordings from the adult abdominal NMJ show a decrease in mEPSP frequency, consistent with the observed decline in NMJ integrity. 4) To investigate whether these defects were progressive, we studied the motor function of larvae and their NMJs. We found that late 3rd instar larvae, but not mid 3rd instar larvae, have a profound crawling defect. Interestingly, the neuromuscular junctions of late 3rd instar larvae are largely normal in appearance and electrophysiological function, suggesting that other changes in the motor circuit account for the decline in motor function. Overall, we observed defects in 1) survival, 2) NMJ integrity, 3) electrophysiology, and 4) motor function. Given the similarity between the *dSod1* knock-in phenotypes and ALS patient symptoms, we anticipate that this model will be a valuable tool for ALS research.

D209 JmjC demethylases regulate resistance and tolerance to alcohol in *Drosophila*. *J. H. Pinzon*, N. A. Shalaby, M. Buszczak, A. Rothenfluh. UT Southwestern Medical Center Dallas, Dallas, TX.

Alcohol exposure affects gene expression in the brain and can lead to addiction in humans and other organisms. Epigenetic changes act on DNA or Histones to alter the transcription, or expression, of genes. Histone modifications include both acetylation and methylation; the latter was considered stable until the discovery of histone demethylases (KDM). Histone methylation/demethylation can promote or silence transcription. The majority of KDMs belong to a group of enzymes that contain a jumonji C (JmjC) domain; these JmjC demethylases regulate several physiological processes. The fact that alcohol and KDMs produce long lasting transcriptional changes suggests JmjC demethylases have a role in alcohol consumption and development of addition. In this study, we assess behavioral changes related to JmjC mutations in *Drosophila melanogaster*. We measured resistance to sedation (ST50 on an initial exposure) and tolerance (percent change in ST50 in a second exposure) towards alcohol in mutants of all 13 *Drosophila* JmjC demethylases genes. Our data shows that mutations in *NO66*, *lid* and *KDM3* (*JHMD2*) alter alcohol resistance and tolerance of flies. Mutations in these three genes cause a reduction in ST50 during an initial exposure to vaporized ethanol. During the second exposure (4hrs after the first), *NO66* and *lid*, showed increased tolerance to alcohol, while *KDM3* displays the opposite with a reduction in tolerance. An analysis of interactive networks revealed *NO66*, *lid*, and *KDM3*, interact with *snr1*, a transcription co-activator involved in dendrite morphogenesis and guidance, that interacts with *rho* and *S* both known to regulate behavioral responses to ethanol. These results suggest JmjC demethylases play a significant role modifying alcohol-related behaviors and further studies are needed to determine its effects on addiction.

D210 Loss of Nardilysin, a chaperone for α-Ketoglutarate Dehydrogenase, causes neurodegeneration in flies and humans and promotes mTORC1 activation. *Wan Hee Yoon*[1,2], Hector Sandoval[2], Sonal Nagarkar-Jaiswal[2], Manish Jaiswal[2], Shinya Yamamoto[2,3], Nele A. Haelterman[2], Nagireddy Putluri[2], Vasanta Putluri[2], Taraka Donti[2], Brett H. Graham[2], Mikiko Ohno[4], Eiichiro Nishi[4], Jill Hunter[5], Donna M. Muzny[2,5,6], Valerie A. Arboleda[7], Stanley F. Nelson[7], Michael F. Wangler[2,3], Ender Karaca[2], James R. Lupski[2,5,6], Hugo J. Bellen[1,2,3]. 1) Howard Hughes Medical Institute, Houston, TX; 2) Baylor College of Medicine, Houston, TX; 3) Jan and Duncan Neurological Research Institute at Texas Children's Hospital, BCM, Houston, TX; 4) Graduate School of Medicine, Kyoto University, Japan; 5) Texas Children's Hospital, BCM, Houston, TX; 6) Human Genome Sequencing Center, BCM, Houston, TX; 7) David Geffen School of Medicine, University of California, Los Angeles, CA.

Here, we isolated *Drosophila Nardilysin (NRD1) (dNrd1)* from a forward genetic screen designed for identification of genes whose loss causes neurodevelopmental or neurodegenerative phenotypes. We show that NRD1 is localized to the mitochondria whereas previous reports have documented a cytosolic, nuclear and plasma membrane localization. Unlike other mitochondrial mutants isolated from the screen, loss of *dNrd1* mutants did not affect reactive oxygen species, and ATP production, or mitochondrial contents. Rather, metabolomic studies and enzymatic assays revealed that *dNrd1* mutants exhibit a striking defect in α-Ketoglutarate Dehydrogenase (OGDH), a rate-limiting enzyme in Krebs cycle. To define the function of NRD1, we performed IP-mass spec and identified OGDH as well as numerous mitochondrial chaperones as NRD1-binding partners. Based on biochemical assays, we showed that NRD1 acts in a mitochondrial chaperoning complex to fold OGDH. Moreover, we show that loss of OGDH phenocopied the loss of NRD1, suggesting that OGDH is a major target of NRD1. A decreased OGDH activity in *NRD1* mutants or *OGDH* knockdown animas caused an increase in α-ketoglutarate, and glutamine levels, which in turn leads to mTORC1 activation, and inhibition of autophagy, resulting in a progressive neurodegeneration. Inhibition of mTOR activity by rapamycin delays the neurodegeneration phenotype in *dNrd1* mutant or OGDH knockdown flies. Furthermore, we describe the identification of two patients with rare variants in *NRD1* or *OGDH-like (OGDHL)* who exhibit a progressive neurodegeneration with an acquired microcephaly and ataxia. Using state of the art technology in *Drosophila*, we demonstrated that the variant in OGDHL in the patient is pathogenic. The cross-species functional studies described here reveal a novel role for NRD1 as a mitochondrial chaperone for OGDH, foster the discovery of two novel human diseases, and provide a potential therapeutic strategy.

D211 A multi-omics strategy for fly models of human disease in exposure biology. *James B. Brown*[1], Sasha Langley[1], Ken Wan[1], Sarah Morris[1], Soo Park[1], Charles Yu[1], Jennifer Kirwan[2], Mark Viant[2], Susan E. Celniker[1]. 1) Lawrence Berkeley National Laboratory, Berkeley, CA; 2) University of Birmingham, UK.

Several of the most prevalent forms of cancer and neurodegenerative disease are linked to chronic low dose pesticide exposure. Low-dose pesticide exposure occurs daily for over 100M Americans. Children exposed to pesticides are twice as likely to develop brain cancer as those unexposed, and mothers exposed to organochlorine pesticides have children with six-fold increased risk for autism spectrum disorders. We model pesticide-induced human disease using chronic exposures in *Drosophila*. Pathways targeted by pesticides exist in off-target organisms, including gut microbes, and low dose exposures may result in microbiome-mediated adverse health outcomes. Ingested chemicals are metabolized, and exposure involves all secondary and tertiary host and microbial metabolites, which may exhibit emergent or compound toxicity. The commensal microbiome of the *Drosophila* gut constitutes an exquisitely simplified model system in which to study the molecular basis of low-dose pesticide susceptibility and resiliency. We used a multi-omics approach (RNA-seq, metabolomics, 16S and metagenomics, phenomics) to study the modes of actions of three widely used herbicides, atrazine, glyphosate and paraquat on fly health. As controls, we studied cadmium chloride (positive control), WY14643 (vertebrate-specific drug, negative control), and alcohol (negative control). All three herbicides radically reshape the gut microbiome community compositions at environmentally relevant doses, and induce concomitant alterations in the fecal metabolome. Cadmium chloride, in contrast, had toxic effects for the host, but no statistically significant action on the gut microbiome. Whole genome PacBio sequencing of gut microbes identifies thousands of new microbial genes, and provides insights into the molecular basis of microbiome remodeling in response to pesticide exposures. Integration with host transcriptomics reveals adaptive responses to atrazine and glyphosate, which are both fully metabolized and undetectable in the feces, and more pronounced stress response to paraquat. Analysis of differentially expressed genes indicates that glyphosate acts as an endocrine disruptor in flies, while atrazine may modify lipid and cholesterol transport and metabolism. Paraquat eliminates Acetobacter in the gut, while atrazine and glyphosate both serve as prebiotics for several microbial clades – increasing population frequencies of basally rare families. The genes modulated by paraquat and atrazine are deeply conserved across the metazoan phylogeny and human. Machine learning on behavioral imaging data identifies phenotypes at all tested dosages, interpretable as lack of coordination – consistent with neurological disease. We predict that epidemiological studies of human populations exposed to Atrazine (33M Americans) will show increased incidence of neuromuscular disease.

D212 Using the DGRP to identify gene networks associated with autism-like behaviors. *L. T. Reiter*[1], D. Flatten[1], D. Johnson[2], K. Hope[1]. 1) Department of Neurology, UTHSC, Memphis, TN; 2) Molecular Bioinformatics, UTHSC, Memphis, TN.

Appropriate social behaviors are essential to humans and animals for reproduction and survival. Defects in social interaction and communication in humans can result in autism spectrum disorder (ASD). Little is understood about the basic neurogenetics controlling complex ASD-like behaviors in humans. Here we use an unbiased quantitative trait locus (QTL) approach in *Drosophila melanogaster* to identify genes and gene interactions that influence 1) social communication during mating (receptive and expressive) and 2) social space interactions in flies.

The Drosophila Genetic Reference Panel (DGRP) has been used to analyze a range of naturally occurring behaviors including sleep, appetite, olfaction, and aggression. The DGRP represent >4,800,00 single nucleotide polymorphisms (SNPs) and >2,900,00 non-SNP variants mirroring the variation for each of 205 individuals in a wild type population. Genetic variation within each line is fixed, while variation across lines represents the naturally occurring variation in the original population. The DGRP is thus the most powerful system available for behavioral genetics among model organisms. Using online genome wide association tools for the DGRP (http://dgrp.gnets.ncsu.edu), we identified genes

associated with ASD-like behaviors across the DGRP lines.

Social communication during mating was used as a proxy for expressive and receptive social communication and social space measured using a social space assay triangle to measure average resting distance among flies. The measures used for genome wide association were time to latency (expressive/receptive communication) and average distance between flies (social space).

We have now identified at least one gene, *sfl* (*sulfateless*), associated with both social communication and social spacing behavior. *sfl* encodes a heparan sulfate N-deacetylase known to be essential for synaptic vesicle endocytosis. We have also identified QTLs in two known ASD gene homologs affecting receptive (neuroligin2) and expressive (Nrx-IV) communication. We have identified QTLs in 130 genes affecting ASD-like behaviors but have only tested ~20% of the fully sequenced DGRP lines. Optimizing resolution and statistical power of these associations will require assessment of all 205 lines for all ASD-like behaviors. Our end goal is to identify new gene-gene relationships or even variants in known ASD genes that are associated with these behaviors in humans.

D213 Defects in phagocytosis by glia and immune cells in a *Drosophila* model of Fragile X syndrome. *M. Shirasu-Hiza*, R. M. O'Connor, E. F. Stone, C. R. Wayne, E. V. Marcinkevicius, J. S. Ziegenfuss, W. B. Grueber, J. C. Canman. Columbia University Medical Center, New York, NY.

We have identified defects in phagocytosis by immune cells in both the brains and bodies of *Fmr1* mutants, a *Drosophila* model of Fragile X Syndrome. Fragile X syndrome is the most common known monogenic cause of intellectual disability and autism, resulting from loss of an evolutionarily conserved translational inhibitor, *Fmr1*. Glia-mediated phagocytosis, the engulfment of extracellular material, is known to play an important role in neuronal structure and function but has not previously been implicated in neurodevelopmental diseases such as Fragile X syndrome. Here we investigate phagocytic immune cell function in *Drosophila Fmr1* mutants. We show that *Fmr1* mutants exhibit delays in phagocytosis by glia—both in the adult, after neuronal injury, and during neurodevelopment of the mushroom body, a brain structure required for learning and memory. In adults, the delay in phagocytosis is associated with a reduction in glial activation--specifically, expression of a crucial glial phagocytic receptor protein, Draper. We further demonstrate that these defects in phagocytosis are common to a second, developmentally independent lineage of blood immune cells in the body, or hemocytes. These results are the first demonstration of a defect in immune cell-mediated phagocytosis in any model of Fragile X Syndrome or autism and suggest the possibility that these defects contribute to the molecular mechanisms underlying neuronal dysfunction in these human diseases. .

D214 Epigenetic control of ribosome biogenesis homeostasis. *Jérôme Deraze*[1], Hélène Thomassin-Bourrel[1], Immane R'kiki[1], Sébastien Bloyer[2], Frédérique Peronnet[1]. 1) Sorbonne Universités UPMC CNRS IBPS UMR 7622, Developmental Biology, 75005, Paris, France; 2) I2BC U Paris Sud CEA CNRS,UMR 9198, 91198 Gif-sur-Yvette, France.

Ribosome biogenesis is an essential yet highly energy-demanding process. Both up- and down-regulation of ribosome biogenesis displays risks of cancer transformation, underlining the necessity for proper maintenance of ribosome metabolism. Proper coordination of its hundreds of factors requires monitoring mechanisms to assess the rate and quality of ribosome synthesis. An increasing body of evidence shows that ribosomal proteins possess regulatory functions outside the ribosome. Those extra-ribosomal functions have been linked in many occasions to the regulation of proliferative and stress pathways in response to perturbation of ribosome biogenesis. As such, they may act both as sensors and regulators of ribosome homeostasis.

We discovered that *Drosophila* Ribosomal Protein L12 (RpL12/uL11) may possess such an extra-ribosomal function. Indeed, we demonstrated that RpL12 can be trimethylated on lysine 3, and that this modification is specifically recognized by the chromodomain of the epigenetic cofactor Corto. As a member of the Enhancer of Trithorax and Polycomb family of cofactors, Corto is involved both in up and down regulation of target genes, through its interaction with Trithorax and Polycomb complexes. Further analysis showed that RpL12 and Corto bind the same *loci* on polytene chromosomes and regulate the same genes, mainly genes involved in ribosome biogenesis (Coléno-Costes et al., 2012, PLoS Genet 8, e1003006).

To determine the biological meaning of this interaction, we have created an RpL12 variant whose lysine 3 is mutated to an alanine (RpL12K3A), preventing its interaction with Corto. To confirm whether it retains the ability to participate in translation, we analyzed its distribution in polysomal fractions. We found that RpL12K3A was associated to actively translating ribosomes, showing that RpL12 methylation is not required for translation. RpL12K3A expression rescues the cell lethality induced by RNAi-mediated depletion of RpL12 in wing imaginal discs but not in adult wings, suggesting that it retains but a part of endogenous RpL12 functions. To test whether RpL12 methylation underlies a role in regulation of transcription, we overexpressed RpL12, RpL12K3A or the Corto chromodomain (CortoCD) in wing imaginal discs and sequenced their transcriptome. We found that ribosome biogenesis genes were repressed by RpL12 and CortoCD, yet insensitive to RpL12K3A overexpression, showing that they are specifically targeted by methylated RpL12. Altogether, these data suggest a role for RpL12 methylation in transcriptional regulation of ribosome biogenesis, possibly involving the epigenetic complexes associated with Corto.

D215 Specialized Ribosomes: eRpL22 paralogue-specific ribosomes translate specific mRNAs in the *Drosophila* testis. *Catherine M. Mageeney*, Vassie C. Ware. Lehigh University, Bethlehem, PA.

Most duplicated ribosomal protein (Rp) genes encode structurally similar or identical protein paralogues. The *Drosophila melanogaster* eRpL22 family is an exception in that encoded proteins eRpL22 and eRpL22-like are not only structurally divergent but are differentially expressed and post-translationally modified within the male germline, strongly favoring the hypothesis that each may have a functionally distinct role(s) in translation or function in an extra-ribosomal capacity in other cellular pathways within the testis. In early stage spermatogonia eRpL22 and eRpL22-like are nucleolar and cytoplasmic, consistent with a ribosomal role. In meiotic and post-meiotic spermatocytes, however, eRpL22 is nucleoplasmic, while eRpL22-like remains cytoplasmic, suggesting a change in role for eRpL22 that may

exclude the paralogue from a role in translation. That eRpL22 paralogues may contribute to ribosome heterogeneity within the male germline in early stages of spermatogenesis and contribute to translational specificity within germ cells is a compelling hypothesis. "Specialized ribosomes" (coined by Xue and Barna, 2012) may direct mRNA translation, or have a unique localization pattern in cells or developmental stages. Here we explore a direct test of this hypothesis by determining what, if any, differences in mRNA translational specificity may exist between ribosomes distinguished by eRpL22 paralogue content. Ribosomal profiling, followed by paralogue-specific affinity purification and mRNA analysis by RT-PCR or RNA sequencing, was performed to determine if eRpL22 paralogues specify a unique class of paralogue-specific "specialized ribosomes" that translate different mRNAs within *Drosophila* testes. We report the association of different mRNAs with eRpL22 paralogue-specific ribosomes, thereby defining different translatomes within the testis. Ubiquitous and early testis-specific transcripts are preferentially associated with eRpL22 ribosomes, found primarily in heavy polysome fractions. eRpL22-like ribosomes (abundant among lighter polysomes) translate some ubiquitous mRNAs and several testis-specific mRNAs, including multiple meiotic and post-meiotic transcripts. Collectively, these data provide compelling evidence for the existence of specialized ribosomes (based on eRpL22 paralogue content) within the male germline that translate different populations of testis- and spermatogenesis stage-specific mRNAs. These data highlight differences in ribosomal functions for eRpL22 paralogues and suggest a novel mechanism (dependent on ribosome composition) that regulates mRNA translation on paralogue-specific polysomes within the male germline.

D216 Translational compensation of segmental aneuploidy in *Drosophila melanogaster*. *Zhenguo Zhang*, Daven Presgraves. University of Rochester, Rochester, NY.

Segmental or chromosomal duplications and deletions, *i.e.*, aneuploidy, can cause aberrant gene expression due to altered gene dosage. Previous studies in Drosophila and yeasts showed that the expression of copy-number altered genes can be compensated at the mRNA level, though remaining different from wild type. In this study, we investigate gene dosage compensation in aneuploid S2 cells at the translational level using public data on mRNA translation rates measured with ribosome profiling. We find that on average copy-number increased (decreased) genes have lower (higher) translation rates than normal genes and that the compensation at the translational level is stronger than at the mRNA level. When combining the compensation effects at both levels, copy-number altered genes have protein synthesis rates (per gene) similar to normal genes— *i.e.*, they are fully compensated. Moreover, we do not find that copy-number altered genes are enriched or depleted in protein-complex genes except for X-linked copy-number-decreased genes, which are depleted in protein-complex genes. Taken together, our results suggest that gene dosage alteration in aneuploids can be further compensated at the translational level.

D217 When One Plus One Does Not Equal Two: Some Tandem Gene Duplicates are Overactive. *David W. Loehlin*, Sean B. Carroll. University of Wisconsin-Madison, Madison, WI.

Tandem gene duplication is an important mutational process in evolutionary adaptation and human disease. Hypothetically, two tandem gene copies should produce twice the output of a single gene, but this expectation has not been rigorously investigated. Here, we show that tandem duplication often results in more than double the gene activity. A naturally occurring tandem duplication of the *Alcohol dehydrogenase* (*Adh*) gene exhibits 2.6-fold greater expression than the single copy gene in transgenic *Drosophila*. This tandem duplication also exhibits greater activity than two copies of the gene in *trans,* demonstrating that it is the tandem arrangement and not copy number that is the cause of overactivity. We also show that tandem duplication of an unrelated synthetic reporter gene is overactive (2.3- to 5.1-fold) at all sites in the genome that we tested, suggesting that overactivity could be a general property of tandem gene duplicates. Overactivity occurs at the level of RNA transcription, and therefore tandem duplicate overactivity appears to be a novel form of position effect. The increment of surplus gene expression observed is comparable to many regulatory mutations fixed in nature, and if typical of other genomes, would broadly shape the fate of tandem duplicates in evolution.

D218 A double assurance mechanism controls enhancer-promoter specificity at the *hunchback* locus. *Jia Ling*[1], Theresa Apoznanski[2], Stephen Small[1]. 1) New York University, New York, NY; 2) New York College of Osteopathic Medicine.

Spatiotemporal gene expression is determined by enhancers, which interact with basal promoters to activate transcription. In genes where multiple enhancers and promoters co-exist at the same gene locus, individual enhancers target their specific promoters to activate. However, the underlying mechanism that regulates this enhancer-promoter interaction is unknown. In the current study, we focused on *hunchback* (*hb*), which contains two promoters: P1P, a maternal and late zygotic promoter, and P2P, an early zygotic promoter, which is activated by two *Bicoid* (*bcd*)-dependent enhancers: P2E and *shadow*. The *shadow* enhancer is located 4kb upstream of P2P but is close to P1P. By using a reporter system that mimics the endogenous *hb* locus and is capable of making a distinction between transcripts from two different promoters, we found that the *shadow* enhancer bypasses P1P and activates the more remote promoter P2P, and that P2E interacts with P2P, but not P1P. To investigate how these specific interactions between promoters and enhancers are regulated, we tested two hypothetical mechanisms: (i) motifs within the targeted promoter guide each enhancer to its specific promoter, and (ii) chromosome architecture, which facilitates contacts between *shadow* and P2E with P2P while blocking P1P. By manipulating TATA box sequences and spacing between regulatory elements in our reporter system and using single-molecule FISH (smFISH), we show that inserting or removing the TATA box of the basal promoters cause subtle changes in the relative RNA outputs of the two promoters, and that chromosome architecture plays a dominant role in preventing P1P from being activated. These results suggest that promoter motifs do affect a promoter's interaction specificity with an enhancer, but whether an interaction happens *in vivo* depends more on the chromosome environment. Overall, our experiments provided evidence for a double-assurance mechanism that provides robust expression of P2P to achieve normal thoracic development.

D219 Tailless repression sets pair-rule stripes and gap domains. *L. P. Andrioli*, G. Castro, F. Clava, W. dos Santos, F. Aguiar, J. Paciência, A. Ferrão-Neto, A. Machado-Lima, L. Digiampietri. EACH, USP, São Paulo, Brazil.

The segmentation cascade establishes the antero-posterior axis specification. The periodicity of the seven striped expression pattern of the segmentation pair rule genes is decisive to form the segments of the thorax and abdomen. However, in the presumptive anterior head region, no pair rule stripes are formed. Stripes are controlled by individual cis regulatory regions (CRMs), and we are working with the hypothesis that at least the CRMs of anterior pair-rule stripes are able to be activated but impeded to be expressed in more anterior regions of the blastoderm, due to the additive activity of several repressors such as *sloppy-paired 1* (*slp1*) and *huckebein* (*hkb*). Our goal is to identify other repressors and investigate transcription regulation mechanisms underlying this network. Here we investigated the activity of *tailless* (*tll*). To accomplish that, we integrated different approaches: genetic and misexpression assays, bioinformatics and biochemistry. We used an image computational tool to detect small perturbations of pair-rule striped patterns and gap domains in different genetic backgrounds. With that we were able to detect small deviations for anterior most pair-rule stripes of *hairy* (*h*) and *even-skipped* (*eve*). *h* 1 and *eve* 1 are anteriorly derepressed in *tll-* and increased effects were detected in *slp-;tll-* embryos, consistent with repression roles of Tll. We further confirmed that using reporter constructs under the control of *h* 1 and *eve* 1 CRMs in the genetic assays. Indeed, with a *tll* misexpression system we confirmed *tll* repression on these CRMs. We also investigated anterior gap genes in different genetic backgrounds and with the misexpression system. We did detect Tll effects on *empty-spiracles* (*ems*) and *buttonhead* (*btd*) in these assays, but not consistent with Tll indirect roles on *h* 1 and *eve* 1. These results point to Tll as being part of an anterior repression mechanism restricting anterior pair-rule stripes CRMs in the anterior blastoderm. Moreover, during our investigations with the misexpression system, we also detected repression effects for the majority of the other pair-rule stripes as well as for central gap genes, although we did not detected derepression for these putative targets in *tll-* or even in *slp-;tll-* double mutants. We discuss the physiological relevance of Tll also being a repressor to impede the expression of central pair-rule stripes and gap domains at the ends of the embryo. Financial support: FAPESP.

D220 Enzymatic modules of the SAGA chromatin-modifying complex play distinct roles in *Drosophila* gene expression and development. *Xuanying Li*[1,2], Christopher Seidel[1], Jerry Workman[1], Susan Abmayr[1,2]. 1) Stowers Institute for Medical Research, Kansas City, MO; 2) University of Kansas Medical Center, Kansas City, KS.

Histone modifications are an important component of epigenetic control. Acetylation is generally associated with gene activation, whereas ubiquitination mediates both activation and repression. Histone modifying enzymes are often integrated into large multisubunit complexes. The modular SAGA chromatin-modifying complex interacts with transcription activators and the TATA-binding protein. It contains two enzymatic modules, with acetyltransferase (HAT) and deubiquitinase (DUB) activities. Using *Drosophila*, we sought to determine whether 1) SAGA is required for transcription of all genes, 2) SAGA dependent genes require both the HAT and DUB modules, and 3) individual modules can function independently of SAGA. We generated germline clone of genes encoding subunits of several modules to eliminate maternal gene product and examined the requirement for SAGA in oogenesis and early embryogenesis. Morphological analysis was used to determine the developmental stage at which mutants of different SAGA modules exhibit defects. Whole transcriptome profiling was used to determine which genes require different SAGA subunits. Lastly, ChIP-seq analysis was used to identify the direct targets of SAGA and its submodules in early embryos. We found that oogenesis is blocked upon loss of Ada2b, a subunit of the HAT module, whereas, germline clone females of Ataxin-7 and non-stop mutants, which are subunits of the DUB module, lay fertilized eggs with no overt defects until cellularization. These findings suggest that transcription essential for oogenesis requires the HAT activity but not the DUB activity of SAGA. Segmentation and D/V patterning appears to occur in embryos lacking the DUB module, as visualized by expression of eve and twi, but these embryos exhibit defects in cellularization. Consistent with this observation, some of the genes involved in cellularization are down regulated in Ataxin-7 GLCs. Whole genome profiling by RNA-seq shows that transcription of a subset of genes, primarily those involved in developmental, are affected by loss of Ataxin-7. ChIP-seq analysis of wild-type embryos revealed that SAGA (monitored by Ada2b) was bound at many, but not all sites bound by polII. Interestingly, ChIP-seq of DUB module proteins revealed their binding to SAGA-bound sites as well as novel sites. In summary, our data suggests that SAGA binds to only a subset of genes in the early embryos, and the DUB module is not required by all of these genes. Moreover, our data is the first to reveal that the DUB module can exist as a free form in wild type embryos that binds to novel locations in the genome.

D221 An ancient yet flexible *cis*-regulatory architecture allows localized Hedgehog tuning by *patched/Ptch1*. *S. Barolo*[1], D. Lorberbaum[1], A. Ramos[1], K. Peterson[2,3], B. Carpenter[1], D. Parker[4], S. De[5], L. Hillers[1], V. Blake[1,5], Y. Nishi[6], M. McFarlane[3], A. Chiang[1], J. Kassis[5], B. Allen[1], A. McMahon[3,6]. 1) University of Michigan Medical School, Ann Arbor, MI; 2) The Jackson Laboratory, Bar Harbor, ME; 3) Harvard University, Cambridge, MA; 4) Elon University, Elon, NC; 5) NICHD, NIH, Bethesda, MD; 6) University of Southern California Keck School of Medicine, Los Angeles, CA.

The Hedgehog signaling pathway is part of the ancient developmental-evolutionary animal toolkit. Frequently co-opted to pattern new structures, the pathway is conserved among eumetazoans yet flexible and pleiotropic in its effects. The Hedgehog receptor, Patched, is transcriptionally activated by Hedgehog, providing essential negative feedback in all tissues. Our locus-wide dissections of the *cis*-regulatory landscapes of fly *patched* and mouse *Ptch1* reveal abundant, diverse enhancers with stage- and tissue-specific expression patterns. The seemingly simple, constitutive Hedgehog response of *patched/Ptch1* is driven by a complex regulatory architecture, with batteries of context-specific enhancers engaged in promoter-specific interactions to tune signaling individually in each tissue, without disturbing patterning elsewhere. This structure—one of the oldest cis-regulatory features discovered in animal genomes—explains how *patched/Ptch1* can drive dramatic adaptations in animal morphology while maintaining its essential core function. It may also suggest a general model for the evolutionary flexibility of conserved regulators and pathways.

D222 Hemocytes as key regulators of respiratory system immunity in adult Drosophila melanogaster. *Katja Brückner*[1], Katrina S. Gold[1,5], Kalpana Makhijani[1,5], Rowan Baginsky[1], Brandy Alexander[1], Katie J. Woodcock[2], Leire Herboso[1], Elodie Ramond[3], Christa Rhiner[4], Eduardo Moreno[4], Bruno Lemaitre[3], Frédéric Geissmann[2], Katja Brückner[1]. 1) University of California San Francisco, San Francisco, CA; 2) King's College London, UK, and Memorial Sloan Kettering Cancer Center New York, NY; 3) EPFL Lausanne, Switzerland; 4) University of Bern, Switzerland; 5) equal contribution.

In adult Drosophila, the role and regulation of blood cells has been controversial and active hematopoietic sites have been proposed. Here we demonstrate that the main activity of the blood cell system in adult Drosophila lies in immunity. We show that the vast majority of blood cells, or hemocytes, are actively phagocytosing macrophages (plasmatocytes). As in many insects, hemocytes in Drosophila accumulate in clusters at the ostia of the adult heart. However, we find that the largest reservoir of adult hemocytes is the extensive respiratory epithelium of the thorax and head (tracheal air sacs), equivalent to the vertebrate lungs. Colonization of these areas depends on (1) developmental timing, in particular the completion of residual phagocytosis of larval tissue in the young adult, and (2) infection-induced localization following exposure to gram-negative or gram-positive bacteria. Hemocyte residence correlates with sites of particle accumulation after injection, illustrating connections of the respiratory tissues with the hemolymph through the open circulatory system. Using time- and tissue-specific permanent genetic lineage tracing, we show that more than half of the adult macrophages derive from the embryonic lineage of Drosophila hemocytes. Genetic and cell biological approaches for the detection of hemocyte proliferation, and the continuous decline of total hemocyte numbers over the course of adult life, do not provide any signs of active blood cell homeostasis or proliferation, both under unchallenged or immune challenged conditions. Consistently, the GATA factor Serpent (srp) marks actively phagocytosing macrophages in the adult animal, in contrast to its expression in prohemocytes during embryonic and larval development. To determine the role of hemocytes in the adult fly, we examined the immune response to bacterial challenge in genetically hemocyte-ablated animals. Interestingly, we find that hemocytes have a key role as sentinels of bacterial infection, promoting the induction of an antimicrobial peptide specifically in the respiratory tissue. We propose the respiratory epithelium of the tracheal air sacs as important immune tissue, which is directly linked with cellular immunity and the blood cell system in adult Drosophila.

D223 Modulation of occluding junctions alters the hematopoietic stem cell microenvironment to trigger immune activation in *Drosophila*. *Rohan Khadilkar*, Katharine Goodwin, Wayne Vogl, Guy Tanentzapf. Department of Cellular and Physiological Sciences, Life Sciences Institute, University of British Columbia, Vancouver, British Columbia, Canada.

The ability of stem cells to self-renew or differentiate is largely dictated by the signals derived from their local microenvironment where they reside, also known as the stem cell niche. During *Drosophila* larval hematopoiesis, the HSC (Hematopoietic stem cell) niche in the lymph gland regulates stem cell self-renewal and their capacity to rapidly differentiate into hemocyte lineages with immune function. Bacterial challenge is known to activate signalling pathways that initiate the humoral immune response in flies. Infection is likely to induce localized changes in the niche triggering the production of factors that promote HSC differentiation. However, the mechanisms by which the HSC's undergo this rapid switch towards the differentiation program is unknown. We show that septate junctions form a previously uncharacterized permeability barrier at the HSC niche regulating the accessibility of the HSC's to niche derived signals. We demonstrate that bacterial infection breaches this permeability barrier and leads to a dynamic outburst of differentiation. Also, genetic disruption of septate junctions at the niche mimics immune activation and provides immune-protection to the flies improving their survival post infection. Our results attribute a novel role for occluding junctions at the HSC niche in acting as a molecular switch between developmental and infection induced hematopoiesis.

D224 The TEAD family transcription factor Scalloped regulates blood progenitor maintenance and proliferation in *Drosophila* through PDGF/VEGFR receptor (Pvr) signaling. *J. A. Martinez-Agosto*, G. Ferguson. UCLA, Los Angeles, CA.

The *Drosophila* lymph gland has been characterized as the definitive hematopoietic organ in which a population of mulitpotent stem-like progenitors, defined by expression of the interleukin JAK-STAT receptor gene *domeless* (*dome*) and located within the Medullary Zone (MZ), is maintained both by a niche and an equilibrium signal emanating from nearby differentiated cells. However, it is not clear what the specific contribution of these progenitors is to the lymph gland during normal development or under immune challenge conditions. Here, we demonstrate a requirement for the TEAD family transcription factor Scalloped in the maintenance and proliferation of hematopoietic progenitors. We have identified a novel population of *domeless* negative progenitors in the early lymph gland that express Scalloped and the PVR ligand PVF2. In this unique population, Scalloped maintains PVF2 expression, which is required for progenitor proliferation and achieving normal lymph gland size. STAT activity marks actively proliferating early blood progenitors, and downregulating its activity causes decreased lymph gland growth similar to loss of Scalloped and PVF2, demonstrating a requirement for PVR/STAT signaling for determining lymph gland size. We further demonstrate that maintenance of *domeless*-expressing progenitors in the MZ is also dependent on a PVR-mediated equilibrium signal that originates from differentiating hemocytes. Pvr activation of STAT in hemocytes mediates expression of adenosine deaminase growth factor (ADGF), which maintains the balance between progenitors and differentiating hemocytes through regulation of extracellular adenosine levels that promote progenitor differentiation. Scalloped loss of function clones lack expression of PVR and depletion of Scalloped in differentiating hemocytes induces complete loss of progenitors, and this phenotype is rescued by overexpression of STAT and ADGF. Therefore, Scalloped function is required in hemocytes to maintain expression of PVR and maintain progenitors of the MZ. Additionally, the immune response to wasp parasitization is dependent on the presence of the pool of MZ progenitors to generate a cellular response to infestation. Scalloped mutants do not mount a lamellocyte mediated immune response to wasp parasitization, demonstrating that Scalloped is also required for the cellular response to infection. Scalloped is required to maintain the hematopoietic niche specifically during immune challenge conditions. These findings expand our mechanistic insight into the signals required to maintain hematopoietic progenitors and the underlying genetic requirements for niche competence essential for mediating the cellular immune response to infection.

D225 Microbial modulation of host lipid metabolism: lessons from *Drosophila*. *Chun Nin (Adam) Wong*[1,2], Wei Song[2,3], John Asara[2,4], Norbert Perrimon[2,3], Paula Watnick[1,2]. 1) Boston Children's Hospital, Boston, MA; 2) Harvard Medical School, Boston, MA; 3) Howard Hughes Medical Institute, Boston, MA; 4) Beth Israel Deaconess Medical Center, Boston, MA.

Lipids are pivotal to animal metabolism, immunity and longevity. While the intestine plays an essential role in digestion, processing and assimilation of dietary lipids, less is known about how commensal microbiota and pathogens may integrate or interfere with host lipid metabolism. Using *Drosophila* as a model, our studies test the effects of the commensal microbiota and the intestinal pathogen *Vibrio cholerae* on host intestinal and systemic lipid metabolism. Confocal microscopy discovered remarkable changes in lipid distribution among tissues, including gut steatosis, when flies were made germ-free or orally infected with *V. cholerae*. Interestingly, this phenomenon is correlated with distinct but striking organ-specific changes in glycerolipid and phospholipid compositions, revealed by lipidomics. Further investigation by target gene expression analysis and the use of transgenic flies suggest commensal and pathogenic bacteria affect host lipid metabolism through different molecular mechanisms that involve enteroendrocine cell signaling and inter-organ communication, pathways that are highly conserved in mammals.

D226 A GWAS Analysis of Genetic Variation in *Drosophila melanogaster* Pathogen Susceptibility. *Jonathan Wang*, Hsiao-ling Lu, Raymond St. Leger. University of Maryland, College Park, MD.

The genetic basis of natural variation in disease resistance are not fully understood. To explore variation to pathogen infection, we used 188 *Drosophila* Genetic Reference Panel lines to perform a genome-wide association analysis for variation to infections with the fungus *Metarhzium anisopliae* (Ma549). We found substantial individual variation in within-host growth and host life span (LT_{50}'s ranged from 3.3 to 7.2 days), with males typically being more resistant than females, and resistant lines restraining fungal growth compared to susceptible lines suggesting that tolerance is less important than resistance in determining natural variation. We found Ma549 LT_{50}'s were moderately correlated with resistance to the bacterium *Pseudomonas aeruginosa*, In addition we found significant correlations with previously published phenotypes including oxidative stress sensitivity, sleep duration and number of "naps", and hemolymph glucose levels. The majority of polymorphisms affecting disease resistance had moderately large effects and were rare, suggesting that there is a general cost to defense involving trade-offs. Nevertheless, disease resistance was not correlated with longevity and fecundity. Many of the genes tagged by the top variants had plausible roles in host defense including components involved in hemocyte migration and phagocytosis, cuticle development, morphogenesis and tissue repair, glycerolipid metabolism, and protein phosphorylation. Several of the candidate genes have human homologs that were identified in studies of human disease, suggesting that genes affecting variation in susceptibility are conserved across species.

D227 Invasion dynamics in the fly gut microbiome. *B. Obadia*, T. Güvener, V. Zhang, W. Ludington. University of California, Berkeley, Berkeley, CA.

Recent studies have shown that the establishment and maintenance of the *Drosophila melanogaster* microbiota depend on constant ingestion of microorganisms, and that bacterial populations vary in richness and diversity over the lifespan of a fly. Animals are constantly faced with new potential invaders of their resident gut microbiota, but only some strains successfully establish themselves. We sought to understand to what extent this variability is probabilistic (*i.e.*, due to chance) *versus* determined by specific host and bacterial traits. We examined these questions in the context of a defined bacterial community of Acetobacter and Lactobacilli in gnotobiotic flies. Using a modified CAFE assay, we delivered a defined dose of bacteria to many hundreds of individual flies and measured their probability of successful colonization and their growth rate in the fruit fly gut. We focused on three different isolates of *Lactobacillus plantarum* (from human saliva, from Canton-S lab flies, and from wild flies). We quantified fitness and niche differences in vitro and in the fly gut, finding minor differences in both. High resolution microscopy indicates that Lactobacillus is capable of colonizing distinct regions of the fly gut. Notably, the wild fly strain had a greater colonization probability, a greater population size, and lower variation in population size than the other strains.

We are currently conducting experiments to determine the sources of the variation between individual flies (*e.g.*, immune activity) and between the different bacterial strains. In invasions of conventionally reared flies, we find that variance in the resident microbiota population increases with increasing input dose of commensal bacteria, indicating that invasion destabilizes the gut microbiota and suggesting that host-microbiota feedbacks may affect population dynamics.

Overall our data invalidate a simple lottery model and suggest a bistable system where invader-host feedbacks induce transitions between the two stable states (colonized *versus* uncolonized), with invasion facilitating more frequent state transitions. The results have implications for not only gut microbiome stability but also for macro-ecological invasions where large variation exists in the success of an invasion.

D228 Molecular analyses of immune-suppressive virus-like particles from a Drosophila parasitic wasp suggest cell-specific activities and a hybrid biotic particle nature. *M. E. Heavner*[1], J. Ramroop[1], G. Gueguen[2], G. Ramrattan[3], G. Dolios[4], M. Scarpati[5], W. Qiu[6], R. Wang[4], S. Singh[5], S. Govind[1]. 1) City College of NY & Graduate Center, CUNY, NY; 2) City College of NY, CUNY, NY; 3) Hunter College, CUNY, NY; 4) Icahn School of Medicine at Mount Sinai, NY; 5) Brooklyn College & Graduate Center, CUNY, NY; 6) Hunter College & Graduate Center, CUNY, NY.

The wasps *Leptopilina heterotoma (Lh)* and *L. boulardi (Lb)*, are obligate parasites of *Drosophila* species. *Lh*, a generalist parasite is successful on many fly species, while *Lb* is a melanogaster specialist. Remarkably, *Lh* silences both the humoral and cellular immunity of its fly hosts, while *Lb* activates humoral but suppresses cellular immunity. This difference in virulence has been attributed to their virus-like particles (VLPs). VLPs are produced in the wasp venom glands and enter the larval hemocoel during oviposition. Morphologically, *Lh* and *Lb* VLPs are similar, with spikes emerging from central particle cores.

Our sequence-based results have uncovered VLP protein classes that suggest an essentially non-viral, microvesicle-like structure with

eukaryotic and prokaryote-like proteins. We have also identified key proteins that might underlie the contrasting virulence strategies of the two wasps. p40, an abundant *Lh* VLP surface/spike tip protein is absent in *Lb.* Our previous work has shown that p40 is synthesized in venom glands and enters the larval hemocytes. Its surface localization and antibody inhibition experiments suggested that p40 mediates VLP interaction with host cell membranes and this interaction is pivotal to lamellocyte lysis.

Imaging studies show that in phagocytic hemocytes (plasmatocytes), VLPs require Rab5 to promote programmed cell death. However, they enter and kill encapsulating hemocytes (lamellocytes) by lysing cell membrane independently of Rab5. Domain analysis and *in silico* modeling of p40 suggests the presence of a fold from SipD/IpaD proteins of Gram negative type III secretion systems. These proteins reside at bacterial needle tips and regulate protein secretion into host cells.

VLPs are abundant in the larval dorsal vessel, within lymph gland progenitors, and around but not within posterior signaling center (PSC) cells. PSC cells are no longer tightly clustered but are instead dispersed in the body of the lobes. Lymph glands are non-responsive to wasps when PSCs are ablated and VLP staining in the lymph gland is low. These studies highlight the PSC's role in immunity and suggest that *Lh* VLPs may inactivate this function.

Our studies shed light on the biotic nature of VLPs and on novel mechanisms of immune suppression likely shared by many other wasp species and active in a variety of *Drosophila* hosts world-wide. (M.E. Heavner & J. Ramroop contributed equally.).

D229 Host-produced Eiger/TNF and the bacterial type 4 secretion system enable susceptibility of *Drosophila melanogaster* to *Coxiella burnetii* infection. *Alan G. Goodman*, Reginaldo G. Bastos. Washington State University, Pullman, WA.

Coxiella burnetii is the causative agent of Q fever, a zoonotic disease that threatens both human and animal health. Due to the paucity of experimental animal models, little is known about how host factors interface with bacterial components and affect pathogenesis. Here we used *Drosophila melanogaster*, in conjunction with the BSL2 Nine Mile phase II (NMII) clone 4 strain of *C. burnetii*, as a model to investigate host and bacterial components implicated in infection. We demonstrated that adult *Drosophila* are susceptible to infection with NMII clone 4 and that this bacterial strain, which activates the IMD pathway, is able to replicate and cause mortality in the animals. We show that in the absence of Eiger, the only known tumor necrosis factor (TNF) superfamily homolog in *Drosophila*, *Coxiella*-infected flies exhibit reduced mortality to infection. We also demonstrated that the *Coxiella* type 4 secretion system (T4SS) is critical for the formation of the *Coxiella*-containing vacuole and an establishment of infection in *Drosophila*. Altogether, our data revealed that the *Drosophila* TNF homolog Eiger and the *Coxiella* T4SS are implicated in the pathogenesis of *C. burnetii* NMII clone 4 in flies. The *Drosophila*/NMII clone 4 model mimics relevant aspects of the infection in mammals, such as a critical role of host TNF and the bacterial T4SS in pathogenesis. Our work also demonstrates the usefulness of this BSL2 model to investigate both host and *Coxiella* components implicated in infection.

D230 Postprandial sleep mechanics in *Drosophila*. *Keith R. Murphy*[1,2], Sonali A. Deshpande[1], James P. Quinn[1], Jennifer L. Weissbach[1], Alex C. Keene[2], Ken Dawson-Scully[2], Robert Huber[3], Seth M. Tomchik[1], William W. Ja[1]. 1) The Scripps Research Institute, Jupiter, FL; 2) Florida Atlantic University, Jupiter, FL; 3) Harvard University, Cambridge, MA; 6) L.

Sleep is regulated by a diversity of processes, such as circadian rhythm, homeostatic rebound, and dietary intake. While these inputs generally affect long-term sleep over hours or days, it is also thought that consuming food can induce an immediate, but transient, rise in sleep. Despite efforts to uncover mechanisms that drive postprandial sleep, little is known about how this behavior is regulated. Here, we developed a system for simultaneously measuring the sleep and food intake of individual *Drosophila* and found that animals experience a transient rise in sleep following meals. The effect of ingestion ranged from slightly arousing to strongly sleep inducing, depending on the amount of food consumed. While sucrose intake is primarily responsible for long-term sleep maintenance, we found that it had no effect on postprandial sleep. Rather, postprandial sleep was positively correlated with ingested volume, protein, and salt—revealing meal property-specific regulation. Silencing of Leucokinin receptor (Lkr) neurons, or Lkr knockdown in these cells, reduced postprandial sleep response specifically to protein ingestion. Paradoxically, silencing a subset of Leucokinin (Lk) neurons increased postprandial sleep, suggesting that Lk has waking outputs normally counterbalanced by Lkr circuitry. This circuitry has also recently been identified as a circadian output module, suggesting that these neurons may serve as an integration point for different types of sleep signaling. These findings reveal the dynamic nature of postprandial sleep and provide a novel system for studying the molecular and neuronal integration of sleep and feeding.

D231 A novel behavioural paradigm of interval timing in *Drosophila*. *W. J. Kim*[1], L. Y. Jan[2], Y. N. Jan[2]. 1) University of Ottawa, Ottawa, Ontario, CA; 2) University of California, San Francisco, San Francisco, USA; 3) University of California, San Francisco, San Francisco, USA.

Time is the fundamental dimension for animal's survival. The animal brain is the result of evolution to orchestrate temporal information across a wide spectrum of time scales. Especially, interval timing is a pivotal function of the human brain to support our cognitive ability such as memory, attention, and decision-making. Interval timing refers to the discrimination of durations in the seconds-to-minutes ranges. The genetic aspects of interval timing have not been vigorously investigated because of the lack of a genetically-traceable model organism. Here we present two novel behavioural paradigms of male *Drosophila* that fits the current 'internal clock model' of interval timing.

1. LMD, Rival induced prolonged mating: *Drosophila* males respond to the presence of rivals by prolonging mating duration to guard female and pass their genes. In previous studies, we examined the genetic network and neural circuits that regulate rival-induced longer mating duration (LMD). LMD can be induced solely via visual stimuli. LMD depends on the circadian clock genes *timeless* and *period*, but not *Clock* or *cycle*. LMD involves the memory circuit of the ellipsoid body (EB) (***Kim et al., Nat. neuroscience***). Further, we identified a small subset of clock neurons in the male brain that regulates LMD via neuropeptide signaling (***Kim et al., Neuron***).

2. SMD, Sexual experience-based shortened mating: *Drosophila* males exhibit a shortened mating duration for guarding female when sexually satiated, called 'Shorter-Mating-Duration (SMD)'. Both sexual experiences and contact-based chemoreception is necessary to induce SMD. SMD requires the sexually dimorphic Gr5a-positive neurons to detect female body pheromones, and can be induced by gustatory stimuli. The memory circuitry within the ellipsoid body (EB) and mushroom body (MB) brain regions are crucial to process this satiety state. SMD depends on the circadian clock genes *Clock* and *cycle*, but not *timeless* or *period*. SMD also relies on signaling via the neuropeptide sNPF, but not PDF or NPF. Sexual experience modifies the neuronal activity of a subset of sNPF-positive neurons involved in neuropeptide signaling, which modulates SMD (***Current Biol. in revision***).

Internal clock model (pacemaker-accumulator model PAM) constitutes of a pacemaker, mode switch, accumulator, memory circuit, and a comparator circuit. We have found that LMD/SMD provides all of these components, which are all identified in the fly brain. This presentation will provide 1) how the fly model of interval timing is similar with that of human and 2) what is the merit of this system.

D232 Scribble Scaffolds a signalosome for active forgetting. *I. Cervantes Sandoval*, R. L. Davis. The Scripps Research Institute, Jupiter, FL.

Forgetting, one part of brain's memory managment system, provides balance to the encoding and consolidation of new information by removing unused or unwanted memories or by suppresing their expression. Recent studies identified the Small G-protein, Rac1, as a key player of the mushroom bodies neurons (MBn), for active forgetting. We subsequently discovered that a few dopaminergic neurons (DAn) that innervate the MBn mediate forgetting. Here we show that Scribble, a scaffolding protein known primarly for its role as a cell polarity determinant, orchestrates the intracellular signaling for normal forgetting. Knocking down *scribble* expression in either MBn or DAn impairs normal memory loss. Scribble interacts physically and genetically with Rac1, Pak3 and Cofilin within the MBn, nucleating a forgetting signalosome that is downstream of dopaminergic inputs that regulates forgetting. These results bind disparate molecular players in active forgetting into a single signaling pathway: Dopamine→ Dopamine Receptor→ Scribble→ Rac→ Cofilin.

D233 The detection of bitter and sweet compounds by the evolutionarily conserved sweet clade in *Drosophila*. *Arun Kumar*, Erica Freeman, Adriana Lomeli, Anupama Dahanukar. University of California Riverside, Riverside, CA.

Detection of energy rich nutrients and potentially toxic compounds is crucial for the regulation of food choices. In *Drosophila*, sweet and bitter tastants are detected by members of a highly diverse family of 68 Gustatory receptors (Grs). Eight of these receptors are expressed in sweet taste neurons and are part of an evolutionarily conserved clade. In a previous study, we developed an *in vivo* functional expression system to individually express these receptors in a unique olfactory neuron that senses carbon dioxide. This neuron is unique because it expresses gustatory receptors, Gr63a and Gr21a, which detect carbon dioxide but do not respond to any known tastants. By expressing sweet taste receptors individually in this olfactory neuron, we found that each receptor responds to unique but overlapping subsets of sweet tastants. We also tested Gr43a, an internal fructose receptor, and its mosquito ortholog AgGr25, and discovered that both receptors respond to fructose as well as other sugars. Thus, all sweet receptors are directly involved in the detection of sweet compounds.

Drosophila have been shown to detect aversive compounds via two different cellular mechanisms – activation of deterrent neurons and inhibition of appetitive neurons. Recent studies have found that an odorant binding protein (Obp49a) is required for bitter tastant inhibition of sweet taste neurons. From a systematic analysis of the dynamics of sweet neuron inhibition, we found that sensitivity to bitter tastants is reduced but not abolished in Obp49a mutants, suggesting that other mechanisms are involved. Moreover, bitter tastants did not evoke the same degree of inhibition when combined with different sugar agonists, raising the possibility of receptor specific antagonist effects. We therefore investigated whether sweet taste receptors were directly inhibited by bitter tastants using the ectopic expression system. We tested seven receptors of the sweet clade individually against a panel of 21 bitter compounds at different concentrations and found that sweet Grs could be directly inhibited by bitter tastants in a dose dependent manner. Moreover, sweet Grs have different sensitivity to different bitter tastants, as well as unique inhibitory response profiles. Interestingly, this property is a distinguishing feature of the sweet Gr clade – neither Gr43a nor the Gr21a/Gr63a receptors are inhibited by bitter tastants. Thus, sweet Grs appear to have evolved to sense both appetitive and aversive compounds.

D234 A peptidergic pathway critical to satiety responses in Drosophila. *S. Min*[1], H. Ryu[2], J. Chung[3]. 1) Seoul National University, Seoul, Seoul, KR; 2) Seoul National University, Seoul, Seoul, KR; 3) Seoul National University, Seoul, Seoul, KR.

Although several neural pathways have been implicated in feeding behaviors in mammals, it remains unclear how the brain coordinates feeding motivations to maintain a constant body weight (BW). To gain insight into this issue, we sought to identify a neural pathway that functions critically in regulation of BW and food intake using Drosophila. To do so, we performed a genetic screen on a collection of neuropeptide GAL4 driver lines expressing a neural silencer using a series of quantitative assays measuring BW and food intake. In our recent study, we reported the identification of a neuropeptide pathway important for BW control via inducing satiety in Drosophila. Silencing of myoinhibitory peptide (MIP) neurons significantly increased BW through augmented food intake and fat storage. Likewise, the loss-of function mutation of *mip* also increased feeding and BW. Suppressing the MIP pathway induced satiated flies to behave like starved ones, with elevated sensitivity toward food. Conversely, activating MIP neurons greatly decreased food intake and BW and markedly blunted the sensitivity of starved flies toward food. Upon terminating the activation protocol of MIP neurons, the decreased BW reverts rapidly to the normal level through a strong feeding rebound, indicating the switch-like role of MIP pathway in feeding. Surprisingly, the MIP-mediated BW decrease occurred independently of sex peptide receptor (SPR), the only known receptor for MIP, suggesting the presence of a yet-unknown MIP

receptor. Together, our results reveal a novel anorexigenic pathway that controls satiety in Drosophila and provide a new avenue to study how the brain actively maintains a constant BW.

D235 A genetically tractable platform for identifying regulators of acute and chronic pain. *S. Im*[1], P. Huang[2], M. Galko[1]. 1) UT MD Anderson Cancer Center, Houston, TX; 2) Rice University, Houston, TX.

Nociceptive (pain) sensitization occurs when tissue damage leads to an adaptive lowering of the threshold for pain behavior. We have developed a platform for studying the genetic basis of adaptive and maladaptive pain modulation. Our unique platform combines UV radiation with quantitative behavioral assessment of thermal or mechanical nociception. To identify conserved genetic players underlying nociceptive sensitization we used tissue-specific RNAi, electrophysiology, cell-based assays, and behavior analysis to discover that *Drosophila* Substance P (Tachykinin) signaling modulates injury-induced nociceptive sensitization by controlling Hedgehog signaling (Im et al., *eLife*, 2015). This is a novel genetic interaction regulating acute sensitization.

While injury-induced nociceptive sensitization is an adaptive modulation of pain, when misregulated it can lead to maladaptive, debilitating chronic pain. To identify regulators of the transition from acute to chronic pain, we performed a tissue-specific RNAi screen looking for genes that led to persistent thermal hypersensitivity when specifically knocked down in multidendritic sensory neurons. Among 150 RNAi lines targeting conserved kinase-encoding genes, we found multiple hits that represent potential regulators of the elusive acute-chronic pain transition. The most striking candidate to emerge from this pilot screen was the *insulin receptor* (*InR*). *InR* knockdown caused prolonged hypersensitivity toward thermal and mechanical stimulation that was not accompanied by defects in baseline nociception (no injury) or acute adaptive sensitization to injury. Thus, the defect in *InR* knockdown larvae is specific to the transition from acute to chronic pain. The identification of *InR* as a regulator of the acute to chronic pain transition prompted us to model painful diabetic neuropathy (PDN), one of the most prevalent complications of diabetes with disabling pain syndromes. Similar to knockdown of *InR*, *Drosophila* models of both type I and type II diabetes exhibited prolonged PDN-like thermal pain hypersensitivity. This data suggest that diabetic conditions in *Drosophila* lead to pathological pain hypersensitivity similar to that experienced by diabetic patients, advocating that our genetically tractable platform is useful for dissecting genetic/molecular mechanisms of PDN pain syndromes. This discovery suggests a completely novel hypothesis not yet investigated in the field, namely that Insulin signaling is required within nociceptive sensory neurons to prevent PDN. We are currently investigating how this PDN-like chronic pain is achieved.

D236 The molecular and cellular basis of pharyngeal taste in *Drosophila*. *Yu-Chieh Chen*, Anupama Dahanukar. UC Riverside, Riverside, CA.

In *Drosophila*, sweet and bitter taste sensation is mediated mainly by gustatory receptors (Grs) expressed in gustatory receptor neurons (GRNs). GRNs are housed within taste sensilla that are distributed in different body parts, including the labellum, pharynx, distal segments of the legs (tarsi), wing margins, and ovipositor. Despite extensive studies that have described taste coding in the main taste organs (labellum and tarsi), little is known about the molecular and cellular basis of pharyngeal taste. Given that the pharynx lies in an anatomical position where it may serve as the last checkpoint for food ingestion, our aim is to explore pharyngeal taste coding for a better understanding how gustatory inputs from different taste organs are weighed and translated into appropriate feeding behaviors.

We first systematically analyzed the expression patterns of *Gr-Gal4* lines representing all Grs via the Gal4/UAS system in three pharyngeal sense organs: labral sense organ, and ventral and dorsal cibarial sense organs.The Gr-to-neuron mapping results reveal distinct pharyngeal sensilla organization as compared to external taste organs.

To specifically study the function of pharyngeal GRNs in feeding behaviors, we took advantage of pox-neuro (*poxn*) mutants, in which the external taste bristles are transformed into mechanosensory bristles. Previously, we showed that *poxn* mutants have intact pharyngeal GRNs, arguing that *poxn* mutants serve as a good tool for dissecting the functional role of pharyngeal GRNs without other confounding taste inputs (e.g. labellar and tarsal gustatory inputs). Using binary choice assays, we found that *poxn* mutants retain similar feeding preferences for most sweet, bitter, salt, amino acid, and acid tastants as compared to wild-type flies. Moreover, we have identified classes of pharyngeal GRNs in mediating both food acceptance and avoidance behaviors, respectively by activating or silencing these pharyngeal GRNs in the *poxn* mutant background. Currently, we are investigating response profiles of pharyngeal GRNs to various tastants by Ca^{2+} imaging, which will allow comparisons of ligand specificity and sensitivity between taste organs.

D237 Ionotropic Receptors mediate thermo- and hygro-sensation in Drosophila. *P. A. Garrity*[1], Z. Knecht[1], L. Ni[1], M. Klein[2], A. Silbering[3], G. Budelli[1], K. Svec[1], A. Samuel[4], R. Benton[3]. 1) Brandeis Univ, Waltham, MA; 2) University of Miami, Coral Gables, FL; 3) University of Lausanne, Lausanne, Switzerland; 4) Harvard University, Cambridge, MA.

The detection of temperature and moisture is critical for survival. Flies must avoid thermal extremes and maintain appropriate body temperatures and hydration levels. The mechanisms by which thermo- and hygro-sensory stimuli are detected remain poorly understood. We find that members of the Ionotropic Receptor (IR) family of invertebrate sensory receptors have crucial roles in both of these sensory modalities. IRs are a large family of receptors (66 IRs in *Drosophila melanogaster*) that have been extensively studied as chemoreceptors. In the olfactory system, broadly expressed IR co-receptors like IR25a combine with more selectively expressed odor-specific IRs to create receptors conferring sensitivity to distinct chemicals. We now show that IR25a combines with members of a distinct group of “orphan” IRs (IRs not previously associated with chemical ligands) to confer sensitivity to thermo- and hygro-sensory stimuli and to drive thermo- and hygro-sensory behaviors. Analogous to IR25a-mediated chemosensing, we find that different IR combinations act in different neurons to mediate physiological and behavioral responses to distinct thermo- and hygro-sensory stimuli. Our data define a new set of combinatorial mediators of

thermo- and hygro-sensation in *Drosophila*, and provide a new view of the relationship between these sensory modalities at a mechanistic level.

D238 A Potential Role for DNA Replication in Establishing Distinct Epigenomes. *M. I. Wooten*[1], V. Tran[3], J. Snedeker[1], R. Ranjan[1], X. Yang[2], J. Buss[2], X. Chen[1]. 1) Johns Hopkins University, Baltimore, MD; 2) Johns Hopkins University School of Medicine, Baltimore, MD; 3) Basic Sciences Division, Fred Hutchinson Cancer Research Center, Seattle, Washington.

Epigenetic mechanisms specify cell fate decisions by altering chromatin structure and gene expression patterns while preserving primary DNA sequences. Epigenetic mechanisms play a key role in specifying and maintaining stem cell identity throughout multiple cell divisions. Many types of stem cells have the ability to asymmetrically divide to give rise to one daughter cell capable of self-renewal and another daughter capable of differentiating. Previously, we discovered that the preexisting H3 is segregated to the male germline stem cell (GSC) whereas newly synthesized H3 is enriched toward the differentiating daughter cell in *Drosophila melanogaster*. Since post-translational histone modifications are a key component of the epigenome, our studies provide the first direct evidence suggesting that stem cells may selectively retain preexisting histones that define their stem cell identity. We have demonstrated that this asymmetric pattern is specific to the canonical H3, but not for histone variant H3.3. Because H3 is incorporated during DNA replication whereas H3.3 is incorporated in a replication-independent manner, our findings suggest a potential role for DNA replication in establishing epigenetic information.

Using super-resolution microscopy, I have been able to study the localization patterns of preexisting vs. newly synthesized histones for histones H3 and H3.3. Whereas histone H3.3 shows no separation between preexisting and newly synthesized histones during DNA replication, histone H3 shows regions of separation approximately 200nm in size. Furthermore, using a technique known as a proximity ligation assay (PLA), I have been able to test whether different histone populations show a strand preference (leading vs. lagging) during their incorporation onto nascent chromatin. By testing the proximity of preexisting and newly synthesized histones to proteins known to be enriched upon the lagging strand, I have generated preliminary data suggesting that newly synthesized histones are preferentially incorporated onto the lagging strand. In addition, I have been able to nucleotide analogues (EdU, BrdU) to observe regions of DNA replication in the *Drosophila* germline. By comparing the replication patterns observed in asymmetrically dividing GSCs to the replication patterns observed in symmetrically dividing progenitor germ cells, I have been able to generate preliminary data suggesting that GSCs coordinate DNA replication in a manner distinct from symmetrically dividing progenitor cells. Based on these data, we propose that GSCs may regulate DNA replication in such a manner that sister chromatids may be built primarily via leading-strand synthesis or lagging-strand synthesis, thereby coordinating the differential deposition of preexisting vs. newly synthesized histones onto distinct sister chromatids.

D239 Sensing Respiratory Gases for the Control of the Hematopoietic System. *B. Cho*[1], C. Spratford[2], F. Chi[2]. 1) Hanyang University, Seoul, KR; 2) University of California, Los Angeles, LA, CA, USA.

Aerobic respiration is the fundamental process in which cells generate energy by consuming oxygen and producing carbon dioxide. Organisms elaborately check the levels of respiratory gases from both internal and external systems for survival. Here, we find a novel link in between the external CO2 sensing cascade and the *Drosophila* hematopoietic system. In the brain, CO2 receptor neuron directly interacts with a small subset of O2 sensing neurons that systemically modulate physiological status according to the respiratory gases. Loss of the CO2 receptor neuron triggers the O2 sensing neuron to lead a hypoxia-like stress through changes in neuropeptides. Changes in the neuropeptide stimulates Notch-mediated cell to cell interaction in the hematopoietic organ, which induces expansion of crystal cells, a hallmark of hypoxic blood. This study provides a mechanistic and novel paradigm for the sensory perceptions of the CO2 gases and their effects on the hematopoietic system that may be conserved in mammals.

D240 Opposite temporal gradients of Imp and Syp govern senescence of neural stem cells via distinct effectors. *Ching-Po Yang*, Tzumin Lee. Howard Hughes Medical Institute, Ashburn, VA.

Senescence of neural stem cells is exquisitely regulated to ensure production of appropriate numbers of neurons that can vary drastically in different neuronal lineages. For instance, while neurogenesis ends in most *Drosophila* brain regions around pupation, the four pairs of mushroom body (MB) neuroblasts incessantly make neurons throughout pupal development. It is unclear what intrinsic and/or extrinsic mechanisms underlie the differential senescence of neural stem cells. We have uncovered that most, if not all, cerebral neuroblasts express the Imp and Syp RNA-binding proteins in opposite temporal gradients that show distinct lineage-characteristic temporal dynamics. The reciprocal Imp/Syp temporal gradients are steep and progress rapidly in non-MB neuroblasts, but get stretched into very shallow profiles in those long-lived MB neuroblasts. Here we report that the lineage-characteristic temporal profiles of Imp and Syp control when particular neuroblasts end in a lineage-autonomous manner. We further demonstrate that Imp and Syp act sequentially through distinct effectors to stop neurogenesis. Taken together with their known roles in specifying serially derived neuronal types, we propose that the opposing Imp/Syp temporal gradients constitute an evolutionally conserved stem cell aging program that govern both the length of neuronal lineages and the diversification of neuronal temporal fates.

D241 A Transcriptional Network Specifies The Intestinal Stem Cell Fate In *Drosophila* Adult Midgut. *Qing Lan*, Min Cao, Rahul K. Kollipara, Jeffrey B. Rosa, Ralf Kittler, Huaqi Jiang. UT Southwestern Medical Center, Dallas, TX.

Increasing evidence indicate that transcription factors (TFs) play an essential role in specifying cell identities. Here, we report the identification of a transcriptional network that maintains intestinal stem cells (ISCs) in *Drosophila* adult midgut. The core module of the network consists of FoxA TF Fkh, E-protein TF Da and SoxE TF dSox9. Our genetic analyses indicate that the ISCs defective in these TFs rapidly

lose their progenitor fates. On the other hand, their ectopic inductions in the progenitors prevent them from differentiating into mature gut cells. We mapped their binding sites in the progenitors and revealed that they bind to many of the same genomic loci and likely regulate a common set of target genes including themselves. In addition, we showed that TFs downstream of several key ISC niche pathways and epigenetic regulators also bind to these same genomic loci. And these shared genomic loci likely function as active enhancers and mediate the induction of progenitor genes. Finally, we explored the interaction between the core module and niche pathways and demonstrated that dSox9 primes Jak-Stat pathway for activation in the progenitors, which in turn induces Emc to suppress Da to promote midgut differentiation.

D242 Niche Appropriation by *Drosophila* Intestinal Stem Cell Tumors. *P. H. Patel*[1,2], D. Dutta[1,2], M. Roca[1,2], B. A. Edgar[1,2]. 1) German Cancer Research Center (DKFZ), Heidelberg, Germany; 2) Center for Molecular Biology, University of Heidelberg (ZMBH), Heidelberg, Germany.

Mutations that inhibit differentiation in stem cell lineages are a common early step in cancer development, but precisely how a loss of differentiation initiates tumorigenesis is unclear. We investigated *Drosophila* intestinal stem cell (ISC) tumors generated by suppressing *Notch* (*N*) signaling, which blocks differentiation. *Notch*-defective ISCs require stress-induced divisions for tumor initiation and an autocrine EGFR ligand, Spitz, during early tumor growth. Upon achieving a critical mass these tumors displace surrounding enterocytes, competing with them for basement membrane space and causing their detachment, extrusion and apoptosis. This loss of epithelial integrity induces JNK and Yki/YAP activity in enterocytes and, consequently, their expression of stress-dependent cytokines (Upd2, Upd3). These paracrine signals, normally used within the stem cell niche to trigger regeneration, propel tumor growth without the need for secondary mutations in growth signaling pathways. Interestingly, we have recently found that tumor growth additionally induces p38 signaling in surrounding epithelial cells. The appropriation of niche signaling by differentiation-defective stem cells may be a common mechanism of early tumorigenesis.

D243 The niche ligand-receptor directly orients the spindle in *Drosophila* male germline stem cells. *C. Chen*[1,2], Y. Yamashita[1,2]. 1) University of Michigan, Ann Arbor, MI; 2) Howard Hughes Medical Institute, University of Michigan, Ann Arbor, MI.

Asymmetric cell division is a critical aspect of many stem cells in balancing self-renewal and differentiation. For those stem cells residing in the niche, spindle orientation with respect to the niche is crucial to achieve asymmetric stem cell division. Despite this critical relationship between the stem cell niche and spindle orientation, the niches' role in spindle orientation is poorly understood. Here we show that, in Drosophila male germline stem cell (GSC) niche, niche ligand Upd and its receptor Dome, but not their downstream JAK-STAT pathway, is required for spindle orientation. We found that the receptor Dome directly interacts with a plus-end microtubule binding protein Eb1 to orient the spindle toward the niche. Live imaging experiments suggest that Dome and Eb1 function to pull the spindle toward the niche. Photoconversion experiments demonstrate that microtubule dynamics is asymmetric between apical and basal half of the spindle, possibly explaining the mechanism by which spindle is pulled toward the niche. Our study reveals a novel mechanism by which the niche directly governs the asymmetric stem cell division via direct regulation of microtubule cytoskeleton.

D244 Somatic cell encystment promotes abscission in germline stem cells after a regulated block in cytokinesis. *K. Lenhart*, S. DiNardo. University of Pennsylvania, Philadelphia, PA.

Stem cell behavior, from rates of cell division to the capacity for self-renewal, is regulated by the specialized microenvironment in which those stem cells reside. A critical function of such niches in many tissues is the coordination of behavior across multiple stem cell lineages. However, the means by which this coordination is achieved are largely unknown. We have identified delayed completion of cytokinesis in germline stem cells (GSCs) as a novel mechanism that regulates the production of stem cell daughters within the testis niche. Through live imaging, we have characterized the delay within GSCs and identified two regulatory mechanisms layered on top of cytokinesis. Following contractile ring disassembly, a novel F-actin ring is formed exclusively in the stem cell population and only in male, but not female, GSCs. This ring is regulated by Cofilin activity and serves to block cytokinesis progress. The duration of this block is controlled by Aurora B activity. Additionally, we have identified a critical requirement for somatic cell encystment of the germline in promoting the final step of GSC cytokinesis. We suggest that this non-autonomous role exists to promote the coordination necessary between stem cell lineages within this niche to achieve robust production of sperm. Together, these findings shed significant insight into a niche-imposed block and reinitiation of cytokinesis in GSCs and why such complex regulation might exist within a stem cell niche.

D245 An intercellular E-cadherin-EGFR relay maintains organ size during renewal by coupling cell division and death. *J. Liang*, S. Balachandra, L. E. O'Brien. Stanford, Stanford, CA.

Self-renewing organs require balanced rates of cell production and loss to maintain a constant number of cells. Cellular imbalance leads to organ hyperplasia or degeneration, but how cellular balance is enforced during normal renewal remains poorly understood. Examining intestinal renewal in Drosophila, we find that feedback inhibition from mature enterocytes to stem cells serves to couple cell death and division and maintain constant cell number. In enterocytes, the adhesion receptor E-cadherin (E-cad) inhibits stem cell divisions not by binding stem cell E-cad, but by repressing the EGF maturation factor *rhomboid* to limit secretion of enterocyte EGFs. Conversely, loss of E-cad upon physiological apoptosis derepresses *rhomboid*, triggering local activation of EGFR in nearby stem cells. EGFR activation induces stem cells to divide, generating new cells to replace apoptotic enterocytes. When enterocyte apoptosis is blocked, stem cells compensate by slowing their divisions. Disrupting E-cad-EGFR feedback inhibition impairs this compensatory response and leads to organ hyperplasia. Our results show that global inhibition of stem cell EGFR is locally relieved when an enterocyte apoptoses. This mechanism couples division and death, ensuring zero-sum cell replacement and constant organ size during renewal.

D246 Poster Awards Presentation. *Nancy Bonini*. The Icahn School of Medicine at Mount Sinai, New York.

D247 Coordination of neuroepithelial specification and neurogenesis modes in the *Drosophila* visual system. *I. Salecker*, H. Apitz. The Francis Crick Institute, London, England, UK.

Vertebrate and invertebrate brains are organized into different areas with distinct neuron subtypes and functions. While we have some insights into the role of region-specific patterning mechanisms, it is not well understood whether alterations in neurogenesis strategies also contribute to circuit diversification.

In the *Drosophila* visual system, neurons in four ganglia originate from two neuroepithelia, the outer (OPC) and inner (IPC) proliferation centers. Neuroepithelial cells in the medial OPC directly convert into neural stem cell equivalents, the neuroblasts, to generate medulla neurons. One IPC subdomain, the proximal (p)-IPC, is dedicated to generating two neuron populations, distal cells and lobula plate neurons that include the motion-detecting T4 and T5 neurons. By contrast, we observed that the p-IPC produces offspring using a different mode of neurogenesis. p-IPC neuroepithelial cells gradually convert into progenitors that migrate within cell streams and acquire neuroblast properties in a second domain, the distal (d)-IPC. Progenitors emerge by an epithelial-mesenchymal transition-like mechanism that in part depends on the Snail transcription factor Escargot and Decapentaplegic signaling. Furthermore, we found that the proneural bHLH proteins Lethal of scute and Asense differentially control the supply rate and maturation of neuroblasts, respectively. Neuroblasts switch expression from Asense to Atonal, a third proneural protein. Cross-regulatory interactions of the Sox protein Dichaete and the orphan nuclear receptor Tailless are essential for the transition from Asense to Atonal expression, and the generation of distal cells to lobula plate neurons. These factors thus act as switching factors of neuroblast competence. Finally, we provide evidence that the neuroepithelial default-state is IPC-like and that retinal determination gene network members play a central role in conferring neuroepithelial identity to the OPC, including its neurogenesis mode by direct conversion into neuroblasts.

We propose that the novel neurogenesis mode in the p-IPC und the underlying regulatory mechanisms could represent general strategies for setting-up a new proliferative zone to facilitate spatio-temporal matching of neurogenesis and connectivity across ganglia.

D248 Growth coordination mechanisms during Drosophila development. *P. Leopold*. Univ Nice / CNRS /Inserm, IBV, Nice, FR.

Body size is an intrinsic property of organisms linked to their developmental program to produce fit individuals with proper proportions. Final size is the result of genetic determinants as well as sophisticated mechanisms adapting size to available resources. Classical regeneration and transplantation experiments have established that different body parts grow according to autonomous programs, challenging the concept of systemic, harmonious growth. Therefore, coordination mechanisms must ensure that all parts have reached an appropriate final size before animals stop growing. Recent advances making use of physiological and genetic approaches have started unravelling some of the cross talks contributing to body growth coordination. In flies, the “coordination hormone” Dilp8 plays a major role in these processes. This relaxin-like hormone is produced by tissues upon growth perturbation. It couples the program of developmental transitions with organ growth by acting on its membrane receptor Lgr3, activating a neural circuitry that is only partially elucidated. Interestingly, animals lacking Dilp8 or Lgr3 present defects in bilateral symmetry, a sign that this novel hormonal system participates in the developmental control of organ growth coordination. In this presentation, I will discuss our recent research aimed at understanding the mechanisms allowing organ/organ growth coordination both in response to abnormal growth (injury/neoplasm) and in the course of normal development (control of developmental stability).

D249 Networking at the nuclear periphery: Contributions of Drosophila LEM domain proteins. *P. K. Geyer*, L. J. Barton, K. E. Lovander, C. Jensen-Cody, W. Ke. Univ Iowa, Iowa City, IA.

Nuclear architecture changes as cell fate specification occurs. During development, chromatin domains adopt distinct spatial distributions, with repressed domains directed to the nuclear periphery. Such positioning depends on the extensive protein network that lines the inner nuclear envelope, known as the nuclear lamina. Included in this network are the LAP2-emerin-MAN1-domain (LEM-D) proteins. This family of proteins binds lamins and tethers repressive chromatin to the nuclear periphery. The importance of the human family of LEM-D proteins is underscored by the fact that loss of individual proteins causes progressive, tissue-restricted diseases, including muscular dystrophy, cardiomyopathy and bone density disorders. Mechanisms by which LEM-D proteins contribute to these diseases are poorly understood. To understand the function of LEM-D proteins, our laboratory has investigated three members of the Drosophila family, Otefin, Bocksbeutel and dMAN1. Genetic studies revealed that each protein has unique and over-lapping functions during development, with loss of individual proteins causing age-enhanced phenotypes. As an example of these development contributions, the LEM-D protein Otefin is uniquely required for oogenesis. Loss of Otefin causes premature death of adult germline stem cells (GSCs) wherein mutant GSCs display features of aging, including altered nuclear structure and chromatin organization. GSC death results from activation of the DNA damage signaling kinases ATR and Chk2. Surprisingly, ATR/Chk2 activation occurs without evidence of DNA damage or transposon transcription. Together, these findings reveal that GSCs have a novel survival checkpoint that depends on nuclear architecture. Our studies suggest that human pathologies result from progressive dysfunction of adult stem cell populations that lead to defects in tissue homeostasis.

D250 Molecular genetics of sex-specific evolutionary innovations. *A. Kopp*. University California, Davis, Davis, CA.

One of the most intriguing features of animal development and evolution is the rapid turnover of sex-specific traits. Most animal species are sexually dimorphic, yet the characters distinguishing males from females are different in every case. This simple observation implies that new sexual characters are gained, and old ones are lost, during the evolution of every animal lineage. The molecular mechanisms of this turnover are poorly understood. We are using the "sex comb" of *Drosophila*, a recently evolved and rapidly diversifying male-specific structure, to elucidate how new sexually dimorphic traits originate and evolve. Key roles in this process are played by the HOX gene *Sex combs reduced* (*Scr*) and by the *doublesex* (*dsx*) transcription factor, the main effector of the *Drosophila* sex determination pathway. Only some cells in *Drosophila* express *dsx*, resulting in a complex mosaic of "sex-aware" and "sex-naive" cells. In *D. melanogaster*, which has sex combs, *dsx* expression in the presumptive sex comb region is activated by *Scr*, and the male-specific isoform of *dsx* up-regulates *Scr* so that both genes become expressed at high levels in this region in males but not in females. Precise spatial regulation of both *dsx* and *Scr* is essential for defining sex comb position and structure. Comparative analysis of *Scr* and *dsx* expression reveals a tight correlation between sex comb size, position, and morphology and the expression patterns of both genes. In *Drosophila* species that primitively lack sex combs, no *dsx* expression is observed in the homologous region while *Scr* shows no male-specific upregulation, suggesting that the origin and diversification of sex combs were linked to the gain of a new, *Scr*-dependent expression domain of *dsx*, and to the evolution of the *Scr*/*dsx* autoregulatory loop. At the molecular level, these changes were caused by the origin of a new *cis*-regulatory element that drives *dsx* expression in the sex comb, and by changes in the spatial activity of *Scr* enhancers. Two other, distantly related fly lineages that independently evolved novel male-specific structures show convergent evolutionary gains of *dsx* expression in the corresponding tissues. Thus, changes in the spatial regulation of sex-determining genes may be a key mechanism that enables the evolution of new sex-specific traits, contributing to some of the most dramatic examples of phenotypic diversification in nature.

MOUSE GENETICS 2016 CONFERENCE

Plenary and Platform Session Abstracts

Mouse Genetics 2016

SCHEDULE AT-A-GLANCE

Wednesday, July 13		
2:00pm-9:30pm	Speaker Ready Room Open	Hall of Cities - Anaheim
7:00pm-9:00pm	Scientific Session: International Resources	Crystal Ballroom G1
9:00pm-11:00pm	Opening Mixer with Exhibits	Cypress Ballroom
Thursday, July 14		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities -Anaheim
7:45am-10:00am	Genetics and Determinants of Health Joint Plenary Session	Palms Ballroom
8:00am-4:00pm	Exhibits Open	Cypress Ballroom
9:00am-8:00pm	Demo Room: MOD (FlyBase, MGI, SGD, WormBase, Zfin) Demo Room Open	Palms Ballroom Canary 3-4
10:30am-12:30pm	Scientific Session: Comparative Genomics, Computational Methods and Evolution	Crystal Ballroom G1
12:30pm-1:30pm	Mentoring Roundtables #1	North Tower - Harbor Beach
12:30pm-1:30pm	Speaking Up for Genetics and Model Organism Research	Crystal Ballroom H
1:30pm-3:30pm	Poster Presentations 1:30pm-2:30pm: Even-numbered poster 2:30pm-3:30pm: Odd-numbered posters	Cypress Ballroom
1:30pm-3:30pm	GeneticsCareers Center and Job Fair	Cypress Ballroom 1C
4:00pm-6:00pm	Scientific Session: Development	Crystal Ballroom G1
4:00pm-6:00pm	Plenary Session and Workshop for Undergraduate Researchers	North Tower - Sawgrass
7:45pm-9:45pm	Scientific Session: Translational and Systems Genetics	Crystal Ballroom G1
10:00pm-11:30pm	*Science Cafe Event	Palms Ballroom Sabal
Friday, July 15		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities - Anaheim
8:00am-9:30am	Scientific Session: Technological Innovations	Crystal Ballroom G1
8:00am-4:30pm	Exhibits Open	Cypress Ballroom
9:00am-8:00pm	Demo Room: MOD (FlyBase, MGI, SGD, WormBase, Zfin) Demo Room Open	Palms Ballroom Canary 3-4
10:00am-12:00pm	Scientific Session: Human Disease Models 1	Crystal Ballroom G1
12:00pm-1:30pm	*Editor's Panel Discussion and Roundtable	North Tower - Harbor Beach
1:30pm-3:30pm	Poster Presentations 1:30pm-2:10pm: "A" poster authors present 2:10pm-2:50pm: "B" poster authors present 2:50pm-3:30pm: "C" poster authors present	Cypress Ballroom
1:30pm-3:30pm	GeneticsCareers Center	Cypress Ballroom 1C

** Ticketed Event*

#TAGC16

Friday, July 15 (continued)		
2:00pm-2:45pm	GeneticsCareers Workshop - Nailing the Job Talk	Cypress Ballroom 1B
4:00pm-6:00pm	Scientific Session: Epigenetics	Crystal Ballroom G1
6:00pm-7:30pm	*Women in Genetics Panel and Networking	North Tower - Harbor Beach
7:30pm-9:30pm	Development and Evolution Joint Plenary Session	Palms Ballroom
Saturday, July 16		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities - Anaheim
8:00am-10:00am	Workshops: See topics and descriptions in the Workshop Section	Multiple locations
8:00am-12:00pm	Exhibits Open	Cypress Ballroom
8:00am-9:00am	Trainee Bootcamp Workshops: Session 1	North Tower
9:00am-10:00am	Trainee Bootcamp Workshops: Session 2	North Tower
10:00am-12:00pm	Poster Presentations 10:00am-11:00am Odd-numbered posters 11:00am-12:00pm Even-numbered posters	Cypress Ballroom *(Posters must be removed by 1pm)*
10:00am-12:00pm	GeneticsCareers Center	Cypress Ballroom 1C
10:30am-11:15am	GeneticsCareers Workshop	Cypress Ballroom 1B
12:15pm-1:45pm	*Mentoring Roundtables #2	North Tower - Harbor Beach
1:45pm-3:45pm	Scientific Session: Cancer and Immunology	Crystal Ballroom G1
4:00pm-6:00pm	Scientific Session: Rosa Beddington Lecture Stem Cells	Crystal Ballroom G1
6:00pm-6:30pm	IMGS Business Meeting	Crystal Ballroom G1
Sunday, July 17		
8:00am-10:00am	Scientific Session: Human Disease Models II	Crystal Ballroom G1
10:30am-12:30pm	Technology and its Application Joint Plenary Session	Palms Ballroom

** Ticketed Event*

M251 Building the first comprehensive functional catalogue of a mammalian genome. *M. Hrabé de Angelis*, International Mouse Phenotyping Consortium, www.impc.org. Institute of Experimental Genetics, Neuherberg, Bavaria, DE.

A major challenge facing mammalian genetics over the next decade is the systematic and comprehensive annotation of mammalian gene function. As part of the International Knockout Mouse Consortium, several programmes are ongoing to generate conditional mutants for all mouse genes. An even greater challenge will be the determination of phenotypic outcomes for each mutation and the identification of disease models. The International Mouse Phenotyping Consortium (IMPC, www.impc.org) is undertaking the development of a comprehensive Catalogue of Mammalian Gene Function. The IMPC incorporates 20 major mouse centres around the world that undertake mouse production and phenotyping. The IMPC programme has two phases: Phase 1, 2011-2016, is approaching completion and will deliver the phenotypes of around 5000 mouse mutant lines; Phase 2 from 2016-2021 will undertake the analysis of the remaining genome. IMPC centres operate a core, standardised, broad-based adult phenotyping pipeline encompassing the major biological and disease systems, including gross pathology and tissue collection as a mandatory requirement. Many centres have also begun to employ a standardised embryonic phenotyping pipeline to analyse the many homozygous lethals, incorporating an assessment of time of lethality and morphological defects. In addition, lacZ expression data is being collected for adult organs and E12.5 embryos. All data from each production and phenotyping centre is uploaded to a central Data Coordination Centre (DCC), and following QC and analysis is archived and disseminated to the wider biomedical sciences community along with appropriate annotation tools. In the first 4 years of the programme, nearly 8000 ES cell lines have been injected, over 5000 mouse mutant lines generated and phenotype data from nearly 3500 mutants collected at the DCC. We will describe many new insights into the genetic and molecular bases of disease, report the generation of numerous novel disease models, and elaborate a fundamental appraisal of the pleiotropic landscape of mammalian gene function.

M252 Large-scale discovery of embryonic lethal phenotypes in mice. *S. A. Murray*[1], A. M. Flenniken[2,13], X. Ji[3], L. Teboul[4], M. D. Wong[2,11], J. K. White[5], T. F. Meehan[6], H. Westerberg[4], M. Justice[7,14], M. Hrabe de Angelis[8,17,18], Y. Herault[9], T. Mohun[10], R. M. Henkelman[2,11], S. D. Brown[4], K. C. Lloyd[12], C. McKerlie[2,13], D. Adams[5], A. L. Beaudet[14], M. Bucan[15], M. E. Dickinson[16], The International Mouse Phenotyping Consortium. 1) The Jackson Laboratory, Bar Harbor, ME; 2) Toronto Centre for Phenogenomics, Toronto, Ontario, Canada; 3) Genomics and Computational Biology Program, Perelman School of Medicine, University of Pennsylvania, Philadelphia PA 19104; 4) Medical Research Council Harwell (Mammalian Genetics Unit and Mary Lyon Centre), Harwell, Oxfordshire, UK; 5) The Wellcome Trust Sanger Institute, Wellcome Trust Genome Campus, Hinxton, Cambridge, UK; 6) European Molecular Biology Laboratory- European Bioinformatics Institute, Wellcome Trust Genome Campus, Hinxton, Cambridge, UK; 7) The Hospital for Sick Children, Toronto Ontario, Canada; 8) Helmholtz Zentrum München, German Research Center for Environmental Health, Institute of Experimental Genetics and German Mouse Clinic, Neuherberg, Germany; 9) Institut Clinique de la Souris (ICS), PHENOMIN, Illkirch, Cedex, France; 10) The Francis Crick Institute Mill Hill Laboratory, The Ridgeway, Mill Hill, London A, UK; 11) Mouse Imaging Centre, The Hospital for Sick Children, Toronto, Ontario, M5T 3H7, Canada; 12) Mouse Biology Program, University of California, Davis; 13) Mount Sinai Hospital, Toronto, Ontario, Canada; 14) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX USA; 15) Departments of Genetics and Psychiatry, Perlman School of Medicine, University of Pennsylvania, Philadelphia PA 19104; 16) Department of Molecular Physiology and Biophysics, Houston, Texas, USA; 17) Chair of Experimental Genetics, School of Life Science Weihenstephan, Technische Universität München, Freising; 18) German Center for Diabetes Research (DZD), Neuherberg, Germany.

Nearly one third of all mammalian genes are essential. Embryonic lethal genes identified and characterized through mouse knockouts (KO) have greatly furthered our understanding of gene and pathway function. The overarching goal of the Knockout Mouse Phenotyping Program (KOMP2) and its partners in the IMPC International Mouse Phenotyping Consortium (IMPC) is to generate an encyclopedia of gene function through genome-wide generation and phenotyping of knockout mice. Collectively, the consortium has produced over 5000 knockout strains and identified over 400 embryonic lethal genes. To characterize the lethal lines, we have built and implemented a high-throughput embryo phenotyping pipeline, which includes the use of high-resolution 3D imaging for the generation of rich datasets that are distributed to the scientific community. The screen has revealed numerous phenotypes in genes with no previously ascribed function, and added new annotations to a subset of genes with prior knockout data. Unexpectedly, our analysis reveals frequent incomplete penetrance and variable expressivity of developmental phenotypes despite a defined genetic background. In addition, we found that human disease genes are highly enriched for in the essential genes identified in our screen, thus providing a novel dataset that facilitates prioritization and validation of mutations identified in clinical sequencing efforts.

M253 3D image analysis of embryonic lethal mutations: An IMPC/KOMP2 resource. *M. E. Dickinson*[1], A. Flenniken[2,3], X. Ji[4], L. Teboul[5], M. D. Wong[2,3], J. K. White[6], T. Meehan[7], W. J. Weninger[8], H. Westerberg[5], C.-W. Hsu[1], M. J. Justice[1,3], Y. Herault[9], T. Mohun[10], A.-M. Mallon[5], R. M. Henkelman[2,3], S. D. Brown[5], K. C. Lloyd[11], A. L. Beaudet[1], M. Bucan[4], S. A. Murray[12], The International Mouse Phenotyping Consortium. 1) Baylor College of Medicine, Houston, TX; 2) Toronto Centre for Phenogenomics, Toronto, Ontario, M5T 3H7, Canada; 3) The Hospital for Sick Children, Toronto Ontario, M5G 1X8, Canada; 4) Genomics and Computational Biology Program, Perelman School of Medicine, University of Pennsylvania, Philadelphia PA 19104; 5) Medical Research Council Harwell (Mammalian Genetics Unit and Mary Lyon Centre), Harwell, Oxfordshire, UK; 6) The Wellcome Trust Sanger Institute, Wellcome Trust Genome Campus, Hinxton, Cambridge, CB10 1SA, UK; 7) European Molecular Biology Laboratory- European Bioinformatics Institute, Wellcome Trust Genome Campus, Hinxton, Cambridge, UK; 8) Centre for Anatomy and Cell Biology, Medical University of Vienna, Vienna, Austria; 9) Institut Clinique de la Souris (ICS), PHENOMIN, Illkirch, Cedex, France; 10) The Francis Crick Institute Mill Hill Laboratory, The Ridgeway, Mill Hill, London A, UK; 11) Mouse Biology Program, University of

California, Davis; 12) The Jackson Laboratory, Bar Harbor, Maine, USA.

Mutant mice provide a rich resource to identify and understand gene function. The overall goal of the International Mouse Phenotype Consortium (IMPC) and the Knockout Mouse Project (KOMP2) is to utilize comprehensive, broad-based, high-throughput phenotyping to characterize phenotypes resulting from null alleles in all ~21,000 functional genes within the mouse genome. To date, over 5000 mutant mice have been generated and consistent with other large-scale mutant screens, 35% of these genes are essential for embryonic and neonatal development. To describe the embryonic and neonatal phenotypes in recessive lethal mutations, a high-throughput pipeline has been established. The pipeline is being used to define the window (embryonic/postnatal) stage of lethality, to assess gross morphology and to generate 3D imaging data. The imaging data is used to identify structural defects and then it is curated and made available to the scientific community. Here, we will describe the imaging technologies, resources to visualize the data, unique phenotypes revealed with 3D imaging and future directions to enhance this resource.

M254 The DMDD programme: an online database of embryonic lethal mouse gene mutations. *T. Mohun*[1], and the DMDD Consortium[1,2,3,4,5,6,7,8]. 1) The Francis Crick Institute, London, UK; 2) Wellcome Trust Sanger Institute, Cambridge, UK; 3) Babraham Institute, Cambridge, UK; 4) King's College London, London, UK; 5) University of Oxford, Oxford, UK; 6) MRC Human Genetics Unit, Edinburgh, UK; 7) Medizinische Universität Wien, Vienna, Austria; 8) UCL, London, UK.

The DMDD programme (Deciphering the Mechanisms of Developmental Disorders) provides a free online database of embryonic-lethal mouse gene knockouts and their related phenotypes. This Wellcome Trust-funded research programme is a unique and expanding resource for both developmental biologists and clinicians, offering a novel way to study embryo development and the possible aetiology of human developmental disorders.

Embryos are comprehensively imaged using high-resolution episcopic microscopy (HREM), allowing them to be examined in 3D at an unprecedented resolution. A team of expert anatomists then scores structural abnormalities in tissue organisation and organ structure using a standardised phenotype ontology. Embryo placentas are examined by histology to assess the impact of gene mutation on placental development, while for perinatal deaths the neural tissue in the brain and spinal cord are examined using immunohistochemistry.

The DMDD database (http://dmdd.org.uk) is continually updated with new results and currently holds data from over 300 embryos, comprising nearly 3 million images. Each embryo can be viewed in a stack viewer at full (3 micron) resolution and tools are provided to allow rapid navigation in all 3 orthogonal planes. All phenotype information is available in tabular form and is also identified within the appropriate images. Data is presented both by embryo and by mouse line, enabling both the severity and penetrance of each phenotype to be assessed. Image data from different embryos can be viewed side by side and a reference library of datasets from normal embryos at different stages of development is also available for comparison.

Powerful search functions increase the potential of the database, enabling users to identify relevant data by gene, tissue or phenotype. All data is available for download on request, while mouse lines of interest can be obtained from the European Mutant Mouse Archive (EMMA) for further study.

DMDD data has already suggested links between specific genes and abnormal embryonic heart structure, and shed light on the importance of gene mutations on the developing placenta. The database offers a wealth of information to be explored by those researching specific genes or developmental disorders, and has the potential to identify previously unknown links between groups of genes or phenotypes.

M255 GENCODE: using new technologies to improve reference mouse genome annotation. *Mark Thomas*, Jennifer Harrow, GENCODE Consortium. Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom.

Understanding transcriptional complexity is important for the study of disease, especially now that CRISPR-Cas9 technologies are driving a genome-editing revolution. The GENCODE resource is now the default human gene set in the UCSC and Ensembl genome browsers, and we are currently working to improve reference mouse genome annotation. With an emphasis on alternative splicing, our current release (M9) contains 115,125 transcripts from 21,971 protein coding and 9,436 long non-coding genes. The increasing availability of next-generation sequencing data from RNAseq, CAGE and PolyAseq allows us to define transcribed regions with ever increasing accuracy; adding to the transcriptional complexity of the genome. Identifying functional transcripts is particularly important, so as to differentiate them from transcripts arising via stochastic events or spliceosomal errors. The function of most protein coding transcripts is evident from the encoded protein, where as the function of long non-coding transcripts is more difficult to determine.

In an effort to improve our functional understanding of transcripts, we are combining phyloCSF comparative data with advances in ribosome profiling and mass spectrometry to assess the coding potential of transcripts. Combining these approaches not only allows us to improve protein coding gene annotation, it also highlights how differences in the precise TSS can influence the translational start of proteins. This has actually resulted in a decrease in the total number of mouse protein coding genes, while the number of pseudogenes has increased. The number of long non-coding RNA transcripts is also increasing, with longer reads from PacBio RNAseq and Capture-Seq experiments improving transcript annotation. With the increased effort, we now have regular releases of the mouse GENCODE gene set for the C57BL/6 reference genome. We are also collaborating with the Sanger Mouse Genomes project to extend annotation to *de novo* genome assemblies for the other laboratory mouse strains.

M258 Beyond the spreadsheet. *K. F. Manly*. UNC Chapel Hill, Chapel Hill, NC.

The development of widely-available computers, growing each year more powerful and less expensive, has helped make genetics an information science. This computer revolution, beginning 40 years ago, also offered many scientists an alternative career. Since about 1988 I have been developing software to support aspects of mouse genetics. The Map Manager programs supported mapping of Mendelian and quantitative trait loci with mouse crosses and recombinant inbred lines. They offered a graphical user interface, unusual at that time for scientific software. As the potential of the Web became apparent, Rob Williams and I developed WebQTL, which brought this type of analysis online. A few years later, an international consortium started the Collaborative Cross (CC) to produce a set of recombinant inbred mouse lines with more genetic diversity. Breeding began in Israel, Australia, and at the Oak Ridge National Laboratory in the US. As breeding began, I began writing software, now called CCDB, to guide and document the development of the ORNL lines. During inbreeding of these lines, we discovered that a program for display of human pedigrees, CraneFoot, could be adapted for mouse pedigrees. As some lines approached inbred status, I wrote two database programs: (1) RXDB to document production of RIX hybrid lines from CC inbreds, and (2) BOTA to maintain records of tissue and DNA samples from many stages of breeding. The most recent project, now replacing CCDB and RXDB, is BOBS, a program to guide and document the production and distribution of CC lines and RIX hybrids to the mouse genetics community. The database programs for CC have had two goals: first, to ensure accurate data entry, secure storage and flexible information retrieval; second, to minimize data entry time by adapting data entry to laboratory and mouseroom procedures.

M259 Good dad, bad dad: the genetic basis of parental care *Hopi Hoekstra*, Andres Bendesky, Young-Mi Kwon, Jean-Marc Lassance, Caitlin Lewarch, Shenquin Yau, Brant Peterson, Meng-Xiao He, Catherine Dulac. HHMI/Harvard University, Cambridge, MA.

Parental care is critical to offspring survival, yet we know little about how genetic differences affect the brain to modify parental care. Using a monogamous and a promiscuous species of deer mice (genus *Peromyscus*), which we show have large differences in parental behaviour, we perform a genetic screen to identify loci that affect parental care. We find that some loci have a specific effect on single parental traits whereas other loci affect modules of traits; moreover, some loci act in a sex-specific manner whereas others have similar effects in both sexes. Importantly, we also drilled down into one locus associated with parental nest building that contains the vasopressin gene and find that vasopressin is expressed at higher levels in the hypothalamus of the promiscuous species, which builds less sophisticated nests. Using chemogenetic studies in laboratory mice, we demonstrate that exciting or repressing vasopressin neurons can suppress or promote nest building, respectively. Together, our genetic dissection of parental behaviour opens exciting new avenues of research for the neurobiological understanding of complex social behaviour such as parenting.

M260 Accumulation and detection of germline spontaneous mutations in C57BL/6JJcl inbred mouse strain. *Y. Gondo*[1], R. Fukumura[1], K. Mori[2], A. Toyoda[3], Y. Ishitsuka[1], S. Makino[1], H. Kotaki[1], Y. Nakai[1], S. Kuhara[2], A. Fujiyama[3]. 1) Riken BioResource Ctr, Tsukuba, JP; 2) Kyushu University Fac Agr, Fukuoka, JP; 3) Ctr Info Biol, Comp Genomics Lab, Mishima, JP.

Spontaneous mutations originate evolution. Kimura's neutral theory elucidated the fixation rate of neutral mutations to be equal to the mutation rate of $1X10^{-8}$/yr. On the other hand, mutation rate, encompassing neutral mutation rate, varies depending on gender, genetic background, environmental factors and so forth. The estimation of mutation rate is thus critical for the studies on evolution as well as for the assessments of environmental risk factors. The advancement of high-throughput sequencing technologies have made it possible to comprehensively detect and analyze very rare mutations even in mammalian genomes. We here designed a mating scheme to accumulate germline spontaneous mutations, which is universally applicable to any sexually reproductive species. Starting from twelve sets of G1 mating pairs of C57BL/6JJcl inbred mice, we obtained eight G5 females from eight independent pedigrees in which *de novo* germline spontaneous mutations were accumulated by complete outbreeding. The genomic DNA samples of the eight G5 female mice were subjected to whole genome sequencing (WGS). The single nucleotide variation (SNV)-call informatics pipeline subjected to the WGS dataset primarily gave rise to a total of 11,984 SNV candidates. These SNV calls consist of not only *de novo* spontaneous germline mutations that arose somewhere between G1 gametogenesis and G5 fertilization but also SNVs/SNPs predisposed in the twelve sets of the original G1 genomes. For instance, 4,601 primary SNV calls were found to be homozygous in all the eight G5 females; thus, they are the fixed SNPs between C57BL/6J and C57BL/6JJcl strains. The two inbred strains were branched in 1989 and the current mouse genome reference sequence (GRCm38.4) of C57BL/6J is 2.8 Gbps; thus, ~1.6 base substitutions and fixation per Mb on average have occurred in a total of 50 yrs (= 25 yrs X 2) or $3.3X10^{-8}$/bp/yr. One thousand nine hundreds and fifty six SNV calls were found in two or more of the eight G5 females but not completely fixed yet; thus, they are recently-arisen polymorphic SNVs predisposed to the breeder's colony. The remaining 5,427 SNV candidates were identified in only one G5 female as heterozygotes; thus, they are good candidates for the *de novo* germline spontaneous mutations accumulated in the four generations between G1 and G5. We are currently focusing on the validation and identification of the origin of the 5,427 SNV candidates in the eight outbred pedigrees.

M261 Discovery, assembly, and annotation of subspecies specific haplotypes in classical and wild-derived mouse strains. *J. Li*, Keane Thomas. Wellcome Trust Sanger Institute, Cambridge, GB.

The vast majority of modern mouse strains are derived from three *M. Musculus* subspecies: *M. m. domesticus*, *Mus musculus musculus*, and *Mus musculus castaneus*. Currently, the only mouse strain with a fully assembled and annotated genome, C57BL/6J, is primarily *M. m. domesticus* in origin. Apart from a small number of well-studied loci, this has meant the sequence and coding alleles in regions of the genome containing subspecies specific haplotypes are largely unknown. In this project, we have used the whole-genome assemblies produced by the Mouse Genomes Project to create the first genome-wide catalog subspecies specific haplotypes and alleles across 16 laboratory mouse strains,

including wild-derived strains representatives of *Mus musculus musculus*, *Mus musculus castaneus*, and *Mus spretus*.

In this project, we have discovered more than one hundred subspecies specific haplotypes by identifying dense clusters of heterozygous SNPs in the reference genome as a marker and examining the corresponding assembled sequence in the strains. We find many more of these highly polymorphic loci in the wild derived laboratory strains and observe significant enrichment for genes involved in immunity, programmed cell death, kin recognition, neuron development and sensory functions. We successfully reassembled and annotated four immune related loci: *Ifi47* (IRG), *schlafen* and *Nlrp1* loci in four wild derived mouse strains. The results show a startling amount of structural variation compared to other loci in the genome reflecting the remnants of balancing selection and repeated host-pathogen co-evolution. We have identified new allelic forms of these genes, gene shuffling, large translocations, and incorporation of open reading frames (ORFs) from other parts of the genome, including several cases of gene disruption caused by transposable elements, and rearrangement between promoter regions and ORF of gene family members, which significantly alter gene expression levels. The genome structure of these regions will provide the basis for understanding different infection phenotypic responses observed in genetic reference panels such as the Collaborative Cross and the Diversity Outbred Cross.

M262 Post-translational mechanisms buffer protein abundance against transcriptional variation. *G. A. Churchill*[1], S. C. Munger[1], J. M. Chick[2], S. P. Gygi[2]. 1) Jackson Lab, Bar Harbor, ME; 2) Harvard Medical School, Cambridge, MA.

Recent studies have reported low correlation among transcript and protein levels in mouse tissues and human lymphoblastoid cell populations. Here we describe the largest combined RNA-seq and shotgun proteomics study to date, in liver samples from genetically heterogeneous Diversity Outbred (DO) mice. We observe two classes of gene regulation that act on protein levels. Most protein abundance QTL (pQTL) map locally to the gene region and act in cis to affect both message and protein, resulting in high concordance between transcript and protein levels. In stark contrast, proteins with distant pQTL appear largely uncoupled from transcript abundance. We apply a novel conditioning approach to identify causal regulatory proteins and transcripts underlying distant pQTL. We discover that stoichiometric buffering of protein complexes and metabolic pathways is the predominant trans-acting post-translational mechanism that buffers protein levels against cis genetic variation in the protein-coding gene.

M265 Multiple mouse reference genomes defines subspecies specific haplotypes and novel coding sequences. *T. M. Keane*, Mouse Genomes Project consortium. Wellcome Trust Sanger Institute, Cambridge, GB.

The Mouse Genomes Project is nearing the completion of the first draft assembled genome sequences and strain specific gene annotation for 16 laboratory and wild-derived mouse strains. The sequence accuracy of these draft genomes compares favourably to the first release of the mouse genome (MGSCv3), with increased base pair accuracy and comparable structural accuracy. For genome annotation, we have used a hybrid approach that combines evidence from the C57BL/6J Gencode annotation and strain specific transcript evidence (RNA-Seq and Pacbio cDNA) to identify and refine strain specific gene structures and alleles. The strain gene sets have provided many updates to the C57BL/6J genes, including genes that were previously missing or mis-annotated. We observe the largest number of novel gene structures in the wild derived strains. We can now determine the underlying sequence and coding alleles in the subspecies specific haplotype regions of the genome. We have identified over a hundred of these loci to date, finding enrichment in genes related to immunity, olfaction, and sensory function. We highlight examples of some well characterised QTLs that are located in these regions, which will enable more precise targeting and functional studies of these alleles. We show how these new reference genomes can be used to improve the accuracy of gene expression analysis of RNA-Seq from heterogenous mice.

The draft genome sequences and annotation can be viewed through our development UCSC genome browser (http://hgwdev-mus-strain.sdsc.edu/cgi-bin/hgGateway) and the gEVAL assembly browser (http://mice-geval.sanger.ac.uk/index.html), with full Ensembl and UCSC genome browser support coming in 2016.

M266 Symmetry breaking and self-organization in mouse development. *T. Hiiragi*. EMBL, Heidelberg, DE.

A fundamental question in biology is the mechanism by which the embryonic polarity is established during development. Unlike many organisms, mammalian eggs lack polarity and symmetry among cells has to be broken during early embryogenesis. This symmetry breaking results in formation of the blastocyst, consisting of two major cell types, the inner cell mass and trophectoderm, which are distinct in their position and gene expression. Recent studies unexpectedly revealed that morphogenesis and gene expression is highly dynamic and stochastic during this process. What signal breaks the initial symmetry and how stochastic gene expression leads to the reproducibly patterned blastocyst remain open questions about the beginning of mammalian life. We have developed an experimental system to monitor early mouse embryogenesis by live-imaging at unprecedented spatio-temporal resolution. This provides us with a basis for investigating the cellular and molecular mechanism of symmetry breaking and self-organisation in early mammalian development.

M267 A SUMO-Ubiquitin Relay Recruits Proteasomes to Chromosome Axes to Regulate Meiotic Recombination. *Neil Hunter*[1], Prasada Rao[1], Huanyu Qiao[1], Shubhang Bhatt[1], Logan Bailey[1], Hung Tran[1], Sarah Bourne[1], Wendy Qiu[1], Anusha Deshpande[1], Ajay Sharma[1], Connor Beebout[1], Roberto Pezza[2]. 1) Univ California, Davis, Davis, CA and the Howard Hughes Medical Institute; 2) Oklahoma Medical Research Foundation, Oklahoma City, Oklahoma.

Meiosis produces haploid gametes through a succession of chromosomal events that include pairing, synapsis and recombination. These events are highly orchestrated, but the mechanisms that regulate them are poorly understood. We demonstrate that SUMO, ubiquitin and

proteasomes specifically localize along chromosome axes in mouse and mediate major events of meiotic prophase including synapsis and recombination. Axis-localized conjugation of SUMO and ubiquitin and the ensuing recruitment of proteasomes are dependent on just two E3 ligases, RNF212 and CCNB1IP1 (HEI10), previously shown to be essential for crossing over. These proteins mediate a checkpoint-like process in which RNF212-dependent SUMO conjugation stalls recombination by rendering the turnover of a subset of recombination factors dependent on CCNB1IP1-mediated ubiquitylation. We propose that SUMO conjugation establishes a precondition for the regulation of crossing over via selective protein stabilization. Chromosome axes are thus revealed as hubs for regulated protein degradation via SUMO-dependent control of ubiquitin-mediated proteolysis.

M268 SMC5/6 complex is required for the formation of bivalent chromosomes capable of segregation during meiosis I in oocytes. *G. H. Hwang*[1], M. O'Brien[2], F. Sun[2], J. Eppig[2], MA Handel[2], P. Jordan[1]. 1) Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 2) The Jackson Laboratory, Bar Harbor, ME.

The frequency of chromosome segregation errors in oocytes increases as women age, especially after the age of ~35, and results in dramatically increased incidence of miscarriage and developmental abnormalities. Despite the correlation between age and chromosome segregation errors, in most cases the causes remain unknown. Recent work using mouse oocytes has linked the structural maintenance of chromosomes (SMC) complexes to being important for accurate chromosome segregation following meiotic resumption. SMC complexes include three major classes: cohesin, condensin, and SMC5/6. During the first meiotic division cohesin is required to ensure sister chromatids remain associated with one another, and condensin is required for the structural integrity and resolution of bivalents. Until our recent work, the functions of the SMC5/6 complex during oogenesis had not been examined. We show that the SMC5/6 complex is enriched at the pericentromeric heterochromatin, and also localizes along chromosome arms during meiosis. To determine the role of the SMC5/6 complex during meiotic resumption, we constructed a conditional knockout (cKO) allele of mouse *Smc5*. Using the Tg(Zp3-cre)93Knw (Zp3-Cre) transgene we deleted *Smc5* in growing *Smc5*-condition ready ($Smc5^{tm1c(KOMP)Wtsi}$) oocytes prior to meiotic resumption. The *Smc5* cKO mutant mice are infertile. After *in vitro* fertilization of MII oocytes obtained from 3 month-old mice, markedly reduced percentages of 2-cell embryos from *Smc5* cKO were observed, and blastocysts were nearly absent. These *Smc5* cKO mutant oocytes fail to accurately separate homologous chromosomes during meiosis I, and resulted in aneuploid MII oocytes. Despite what appears to be an inability to resolve concatenation between chromosomes during meiosis we did not observe topoisomerase II alpha mislocalization. However, we did observe defects in condensin localization along the chromosome axes. Remarkably, these phenotypes are less prominent when analyzing oocytes isolated from younger mice. We have obtained data to suggest that the SMC5/6 complex remains stable for weeks following ZP3-Cre-mediated deletion of *Smc5*, but levels present prior to deletion diminish with age. Taken together, our results demonstrate that the SMC5/6 complex is essential for the formation of bivalents that are capable of accurate segregation during meiosis I, and age-related meiotic aberrancies may be directly related to a gradual reduction in SMC5/6 protein levels.

M269 Imaging how Transcription Factors Bind DNA to Control Cell Fate in Living Mouse Embryos. *N. Plachta*. A*STAR, Singapore, SG.

Transcription factor (TF) binding to DNA is fundamental for gene regulation. However, it remains unknown how the dynamics of TF–DNA interactions change during cell fate determination *in vivo*. We established imaging techniques to quantify TF–DNA binding in single cells of developing mouse embryos. We show how POU5F1 (OCT4) and SOX2 re-partition between specific and non-specific DNA sites as cells decide their fate *in vivo*. Furthermore, we discover heterogeneities in SOX2-DNA binding appearing as early as the 4-cell stage of development, and regulated by histone methylation, which predict cell fate. Finally, we develop new techniques to show how cells change their shape and position in the embryo to form the pluripotent inner mass.

M270 Maternally provided KDM1A enables the maternal-to-zygotic transition and prevents defects that manifest postnatally. *J. A. Wasson*[1*], A. K. Simon[1], D. A. Myrick[1], G. Wolf[2], S. Driscoll[3], S. L. Pfaff[3], T. S. Macfarlan[2], D. J. Katz[1]. 1) Emory University School of Medicine, Atlanta, GA; 2) Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD; 3) The Salk Institute for Biological Studies, La Jolla, CA.

Somatic cell nuclear transfer has established that the oocyte contains maternal factors with epigenetic reprogramming capacity. Yet the identity and function of these maternal factors during the gamete to embryo transition remains poorly understood. In *C. elegans*, KDM1A (AKA LSD1) enables this transition by removing H3K4me2 and preventing the transgenerational inheritance of transcription patterns. Here we show that loss of maternal KDM1A in mice results in embryonic arrest at the 1-2 cell stage, with arrested embryos failing to undergo the maternal-to-zygotic transition. This suggests that KDM1A maternal reprogramming is conserved. Moreover, partial loss of maternal KDM1A results in striking phenotypes weeks after fertilization; including perinatal lethality and abnormal behavior in surviving adults. These maternal effect hypomorphic phenotypes are associated with alterations in DNA methylation and expression at imprinted genes. These results establish a novel mammalian paradigm where defects in early epigenetic reprogramming can lead to defects that manifest later in development.

M271 A Forward Genetics Approach to Discover Modifiers of Developmental Phenotypes. *K. A. Geister*[1], A. E. Timms[1], S. Ha[1], R. J. Lipinski[2], D. R. Beier[1]. 1) Seattle Children's Research Institute, Seattle, WA; 2) University of Wisconsin-Madison School of Veterinary Medicine, Madison, WI.

The discovery of modifier genes in human and mouse has seen slow progress. In mice, this is largely due to the reliance on inherent variability among inbred strains, which makes identifying the causal variant, even in highly resolved mapped loci, quite challenging. We have

developed a fast and cost-effective method for genetic mapping of causal ENU-induced mutations using Next Generation Sequencing that combines single nucleotide polymorphism (SNP) discovery, mutation localization, and identification of causal sequence variants. This approach precludes the need for an outcross to facilitate mapping, as we use the ENU-induced variants as SNP markers. This strategy allows us to perform both primary screens and modifier screens on fully inbred lines. We have successfully mapped causal mutations using this approach, and we are currently testing the efficacy of this strategy with regard to modifier discovery using two C57BL/6 congenic strains as our sensitized lines. One is a loss-of-function allele of the SHH transcriptional effector *Gli2*, which can be modified by prenatal ethanol exposure to generate holoprosencephaly-like phenotypes. The other is an ENU-induced loss-of-function allele of *Pibf1* that causes cleft lip/palate and ciliopathy-like phenotypes. Both alleles could reveal modifiers of genes involved in craniofacial, brain, and skeletal development as well as those involved in the formation and function of the primary cilium. In the simplest cases, whole-genome sequencing will reveal areas of homozygosity shared between mutants with a consistent "modified" phenotype, and allow us to narrow our focus to the induced variants included in these homozygous regions. We anticipate that we may ascertain more complex genetic interactions as well as new ENU-induced mutant phenotypes that model human birth defects. In our first screen we discovered a mutation in *Colgalt1*(collagen beta (1-O) galactosyltransferase type 1), which is required for proper galactosylation of hydroxylysine residues in a number of collagens. Mutant embryos exhibit skeletal and muscular defects, and we hypothesize that the *Colgalt1* mutant could serve as a model of a human connective tissue disorder and/or congenital muscular dystrophy or myopathy. The mutants also show variable expressivity of cleft palate and exencephaly. Examination of the sequencing data appears to exclude the likelihood that these are due to an unlinked ENU-induced variant, illustrating that stochastic effects remain an important source of variation in developmental phenotypes. Funding: NIH R01 HD36404.

M272 ER stress-induced remodeling of placental mRNA and small RNA expression networks. *Clement Y. Chow*[1], Kevin Klatt[2], Jessica Brown[2], Andrew G. Clark[2], Mark S. Roberson[2]. 1) University of Utah, Salt Lake City, UT; 2) Cornell University, Ithaca, NY.

Placental dysfunction can lead to a variety of pregnancy pathologies, including intrauterine growth restriction (IUGR) and pre-eclampsia (PE). While these two conditions are distinct and can have differing outcomes for the mother and fetus, they share common molecular signatures. High levels of endoplasmic reticulum (ER) stress have been found in placentas from human cases and mouse models of IUGR and PE. The ER is a large organelle responsible for synthesis, maturation, and delivery of proteins essential for cellular function. ER stress occurs when misfolded proteins accumulate in the ER lumen. The cell responds with the conserved unfolded protein response and returns the ER to homeostasis by attenuating protein synthesis, activating transcriptional signaling cascades, and refolding or degrading misfolded proteins. ER stress can result in inflammation, cell death, and disease. The appearance of ER stress in the placenta does not occur in isolation and is accompanied by a variety of changes in maternal physiology. Inhibition of protein synthesis, reduced cell proliferation, or activation of pro-inflammatory pathways are all thought to be associated with differing levels of placental ER stress. This complex milieu makes it difficult to identify the direct effects of ER stress on placental and fetal health. To study the effects of the isolated ER stress response on the placenta, we used Tunicamycin to induce robust ER stress in E10.5 and E14.5 C57BL/6J mouse placentas. Because the response to ER stress involves thousands of gene expression changes, we used RNA-seq to measure the mRNA and small RNA changes associated with ER stress. We find that at each developmental time point, the placenta has a unique response to ER stress, with a specific associated ER stress response profile. We also find that the small RNA network reorganizes in ways that depend on both ER stress and on developmental time. Finally, small RNA expression changes appear to correlate with their targets under ER stress, and this correlation changes with development. Our data demonstrate that there is a complex regulation of mRNA and small RNA expression in the developing placenta, and ER stress impacts this regulatory network in profound ways. These results have important implications for potential roles of ER stress response in the pathophysiology of a variety of placental conditions.

M273 Verne Chapman Lecture: Mendel 2.0, revisiting the determinants of inheritance and the origins of phenotypic variation. *J. H. Nadeau*. Pacific Northwest Research Institute, Seattle, WA.

Mendel's discoveries were a breakthrough in understanding the inherited relations between genotype and phenotype for simple traits. Extending these principles to more complex traits has led to a model of genetic and phenotypic architecture that involves large numbers of genes, each with small additive effects. But considerable evidence suggests that circumstances are more complex. Mendelian traits often depend on strong interactions with genetic background. More recent work with complex traits in genetic reference populations shows that epistasis is pervasive. The strong dependence of both simple and complex traits on genetic background also argues that gene action is conditional rather than constant, although the basis for conditional functions is largely unknown. Strong epistasis implies that a revised picture of genetic architectures is needed.

Phenotypic variation can also result from environmental exposures and genetic variants in ancestral generations. These inherited epigenetic effects, which are independent of DNA sequence variants, can be as common and strong as conventional genetic effects and they can persist for tens of generations. Their significant contribution to phenotypic variation calls for a rethinking of our concept of inheritance and the formulation of heritability.

Finally, a fundamental tenet of Mendelian inheritance is that, with few exceptions, fertilization results from a random union of gametes. However, reanalysis of many reports with mutant genes shows that both specific genetic variants and gene-diet interactions can lead to a strong bias in gamete preferences at fertilization. These cases are unusual because they depend on genetically-determined interactions between specific egg and sperm, unlike conventional forms of transmission distortion. Fertilization bias would have a profound impact not only on measures of inherited disease risk, but also on inherited gene variation.

Together these discoveries involving epistasis, transgenerational epigenetic effects, and fertilization bias argue that genomes are composed of specific combinations of interacting genetic variants that confer viability and fertility as well as resilience to mutational perturbations, that

generations are more continuous than discrete with inherited memories of ancestral genetics and environments, and that fertilization bias helps drive genetic architecture and phenotypic variation across generations.

M274 A suppressor screen in *Mecp2* mice reveals pathways for Rett syndrome pathogenesis. *M. J. Justice*, S. M. Kyle, J. Ruston, R. Zeng. SickKids Research Institute, Toronto, Ontario, Canada.

Mutations in methyl CpG binding protein 2 (*MECP2*) cause Rett syndrome, an X-linked neurological disorder with autistic features and developmental regression. Mutation of *MECP2* causes widespread gene dysregulation, making the syndrome difficult to treat. *Mecp2* mouse mutants provide an excellent animal model to identify molecules that are important for disease pathogenesis. Studies of the mouse model have shown that the symptoms can be reversed by introduction of *Mecp2* and partially rescued by other factors, providing evidence that therapeutic intervention is possible in humans. *MECP2* mutation impacts many biological pathways, but it is unclear which are relevant to symptom onset and progression. A modifier screen is a forward-genetic approach to find mutations that suppress or enhance a phenotype of interest, allowing the organism to reveal important pathways for morbidity. Here, random unbiased mutagenesis with *N*-ethyl-*N*-nitrosourea (ENU) was employed to isolate mutations that suppressed clinical signs and improved overall health in a *Mecp2* mouse model. Strikingly, the lesions identified by whole exome sequencing and segregation in 46 suppressing lines reveal 32 candidate genes that lie in only four pathways. One modifying mutation showed that cholesterol synthesis was abnormal in *Mecp2* mice, and revealed the importance of brain lipid homeostasis to neurological function. Subsequent data show that MECP2 is required to link a repressor complex that regulates lipid homeostasis to DNA. Because MECP2 is ubiquitously expressed, metabolic syndrome also develops in *Mecp2* mice. Many of the suppressor mutations lie in the pathway that regulates lipid homeostasis, and metabolic modulators such as statin drugs improve health. Lipid homeostasis thus represents a potential new therapeutic target for Rett syndrome treatment. Altogether, our data suggest that multiple factors will be required to reverse disease entirely, requiring combination therapies. A similar genetic approach could be exploited to identify targetable pathways involved in other “untreatable” diseases, opening a new field for translational discovery.

M275 Systems Genetics Approach toward Understanding Regulation of MECP2 Expression in the Brain. *Lucy H. Williams*, Rachel C. Mcmullan, Joshua Starmer, Tim A. Bell, Darla R. Miller, Terry R. Magnuson, Fernando Pardo Manuel de Villena. University of North Carolina, Chapel Hill, NC.

Rett syndrome (RTT) is a pediatric neurological disorder that results from dysfunction of X-linked Methyl-CpG-binding protein 2 (*MECP2*). Treatment strategies that are under-development for RTT either target *MECP2* itself or target pathways downstream of *MeCP2*. In the first category, the goal is to normalize *MECP2* expression through molecular techniques such as gene therapy. Targeting *MECP2* is particularly attractive because it may lead to curing RTT yet special attention must be paid to MECP2 dosage. The brain is highly sensitive to perturbation of *MECP2* as over-expression causes MECP2 Duplication syndrome and even subtle fluctuations are associated with a spectrum of neurological disorders, such as autism. We are taking advantage of genetically diverse mouse populations to integrate genetic, genomic (mRNA), proteomic (protein) and epigenetic (X inactivation) level data to address questions: (1) how are *MECP2* transcript and protein levels controlled in the brain? And (2) how does genetic background influence the spectrum and severity of RTT-related phenotypes?

We have quantified *Mecp2* transcript levels in the brain from three different but genetically related mouse populations: 65 Collaborative Cross (CC) strains, 27 F1 hybrid crosses of two different CC strains, and 223 Diversity Outbred (DO) mice. In all three populations, heritability is well over 0.50, demonstrating that expression is under genetic control and is segregating within our reference populations. *Mecp2* expression in the inbred CC strains far exceeds the range of levels quantified between the three most diverse founders of the CC (CAST/EiJ, PWK/PhJ, and WSB/EiJ), demonstrating that *Mecp2* expression is under the control of trans acting factor(s). Using the 223 Diversity Outbred mice, we have mapped trans eQTL. To establish *Mecp2* expression thresholds in the brain, we are quantifying the correlation between steady-state transcript levels and protein abundance. And, we describe here strategies that we will employ to test how outlier levels are associated with clinical features. This work will produce new mouse lines and molecular and behavioral datasets will be valuable tools to map modifiers of phenotypes, inform on the molecular mechanisms that define transcript and protein levels, and develop and test more effective treatment strategies.

M276 Conserved and tissue-specific effects of natural genetic variation on transcript and protein abundance. *S. C. Munger*[1], J. M. Chick[2], P. Simecek[1], K. Choi[1], E. L. Huttlin[2], D. M. Gatti[1], N. Raghupathy[1], K. L. Svenson[1], S. P. Gygi[2], R. Korstanje[1], G. A. Churchill[1]. 1) The Jackson Laboratory, Bar Harbor, ME; 2) Harvard Medical School, Boston, MA.

Genetic variation can influence protein expression through transcriptional and post-transcriptional mechanisms, and these effects may be conserved across tissues or specific to one. To characterize the shared and tissue-specific effects of natural genetic diversity on the proteome, we combined RNA-seq and multiplexed, quantitative mass spectrometry with a genetically diverse mouse population, the Diversity Outbred (DO) heterogeneous stock. We measured genome-wide transcript and protein abundance in livers and kidneys from 192 DO mice, and mapped quantitative trait loci that influenced transcript (eQTL) and protein (pQTL) expression. We identified nearly 3,000 pQTL in each of the liver and kidney, divided equally between local and distant variants. Local pQTL generally had larger effects on protein abundance, these effects were conferred primarily through transcriptional mechanisms, and half showed conserved protein responses in both tissues. In contrast, distant pQTL influenced protein abundance nearly exclusively through post-transcriptional mechanisms and most were observed to be specific to the liver or kidney. We applied mediation analysis and identified a second protein or transcript as the causal mediator for half of the significant distant pQTL. Furthermore, we identified groups of proteins within known pathways that shared coincident subthreshold distant pQTL for which we could identify a single causal protein intermediate from the same pathway, demonstrating the power of integrating ontology and mediation analyses to tease out subtle but real genetic effects from mapping populations with modest sample sizes. Overall, our analysis

revealed extensive tissue-specific networks of direct protein-to-protein interactions that act to achieve stoichiometric balance of functionally related enzymes and subunits of multimeric complexes.

M277 Discovering novel susceptibility genes for aggressive prostate cancer using an integrated, systems-based cross-species strategy. *Jean M. Winter*[1], Derek Gildea[2], Jonathan Andreas[1], Kendra A. Williams[1], Ying Hu[3], Minnkyong Lee[1], Daniel Gatti[4], Tyra Wolfsberg[2], Gary Churchill[4], Nigel Crawford[1], NISC Comparative Sequencing Program. 1) Genetics and Molecular Biology Branch, NHGRI, National Institute of Health, Bethesda, MD; 2) Computational and Statistical Genomics Branch, NHGRI, NIH, Bethesda, MD; 3) Center for Biomedical Informatics and Information Technology, NCI, National Institute of Health, Rockville, MD; 4) The Jackson Laboratory, Bar Harbor, ME.

Prostate cancer (PC) is the most commonly diagnosed cancer in men. However, relatively few (<13%) cases result in death, with many men undergoing unnecessary and invasive treatments. New approaches for assessing patients at higher risk of developing metastatic disease are vital for preventing over-treatment and improving outcomes. We aimed to identify aggressive PC susceptibility genes using the C57BL/6-Tg(TRAMP)8247Ng/J (TRAMP) mouse model of neuroendocrine PC, which demonstrates a particularly aggressive form of oncogenesis. TRAMP mice were bred to Diversity Outbred (J:DO) mice and a cohort of 498 TRAMP x J:DO males was developed in order to identify genetic regions associated with susceptibility to aggressive disease. Modifier locus mapping revealed one locus spanning ~4Mb on Chromosome 8 associated with distant metastasis free survival (LOD=8.42, p=5.33e-6). Candidate genes within this locus were identified by RNA-seq analysis of 195 TRAMP x J:DO tumors. Trait-correlation and expression quantitative trait locus data for transcripts within this locus were integrated with strain-specific SNP data to distinguish eleven candidate metastasis susceptibility genes. Relevance of these genes to aggressive human PC was investigated via in silico validation, in a cohort size over 5,550 prostate cancer patients, which encompassed three independent human PC tumor gene expression datasets and two human PC genome-wide association studies. This identified two novel aggressive PC susceptibility genes: *CENPU (MLF1IP)* and *RWDD4.* Interestingly, *CENPU* acts as a transcriptional suppressor and chromosome segregation protein, and has recently been the focus as a potential gene therapy target for human prostate cancer. The data presented here demonstrate how systems genetics approaches centered on the use of a mouse model of PC can help us understand how hereditary variation influences disease outcomes of aggressive PC. Ongoing work is focusing on *in vitro* and *in vivo* functional characterization of these two genes to better understand their role in metastatic PC.

M279 A Cross-Species Novel Genetic Cell Ablation Technology Involving CD59 and Intermedilysin. *E. C. Bryda*[1], Marina Hanson[1], Suman Gurung[1], Fengming Liu[2], Shen Dai[2], Alison Kearnes[2], Dechun Feng[3], Bin Gao[3], Anand Chandrasekhar[1], Xuebin Qin[2]. 1) University of Missouri, Columbia, MO; 2) Temple University School of Medicine, Philadelphia, PA; 3) National Institute on Alcohol Abuse and Alcoholism, Bethesda, MD.

The ability to selectively ablate cell types in model organisms is a powerful tool for understanding cell lineage, cell function, developmental processes and disease mechanisms. Current methodologies have limitations including lack of cell-type specificity, off–target effects, narrow pharmacological windows, and relatively slow onset of cell death. Our novel system utilizes human CD59 (hCD59), a membrane receptor, and intermedilysin (ILY), a bacterial toxin that binds hCD59 selectively. We have generated multiple rodent models that express hCD59 in a cell-specific manner. We demonstrated 1) ablation of circulating cells in a rat anemia model which expresses hCD59 on erythrocytes for the study of the pathogenesis of hemolysis-associated complications, 2) ablation of cells in a solid organ by generating a mouse model in which epithelial cells in the liver were ablated for the study of liver damage and regeneration, and 3) ablation of neuronal cells in an inducible rat model carrying a transgene with constitutive expression of ZsGreen and hCD59 in the presence of Cre recombinase. The Cre-inducible model can be bred with any conditional Cre recombinase-expressing rat to generate animals with expression of hCD59 and ZsGreen in the cell type/tissue of choice. These models have shown that cell ablation is dose-dependent, rapid, and has a large pharmacological window. Extending these experiments to zebrafish, we performed dose-response studies with *hCD59* RNA-injected and control zebrafish embryos treated with ILY and found that ILY rapidly induced extensive tissue lysis in the embryos expressing hCD59. Current efforts are focused on further characterization of the effectiveness of hCD59-ILY-mediated cell ablation in zebrafish. Together, these studies demonstrate that the hCD59-ILY cell ablation technology has wide utility and can be applied to study virtually any tissue or cell type in the animal species of choice.

M280 RNAi and CRISPR/Cas9 based *In Vivo* Models for Drug Discovery. *P. Premsrirut*[1*], G. Martin[2], L. Dow[3], S. Kim[4], J. Zuber[5], S. Lowe[6], G. Hannon[7]. 1) Mirimus, Inc., Woodbury, NY; 2) Charles River Laboratories, Wilmington, MA; 3) Weill Cornell Medical College, New York, NY; 4) New York University, New York, NY; 5) Research Institute of Molecular Pathology, Vienna, Austria; 6) Memorial Sloan Kettering Cancer Center, New York, NY; 7) Cancer Research UK, Cambridge, Cambridge.

With the advent of CRISPR-Cas9 technology, the speed and precision in which genetically engineered mouse models can be created is unprecedented. We now have at our disposal a genetic toolbox that will enable the rapid generation of sophisticated mouse models of human disease. Recently, an inducible CRISPR-Cas9 (iCRISPR) system was described that enables doxycycline-regulated Cas9 induction of widespread gene mutagenesis in multiple tissues. Previously, we also demonstrated how inducible RNA interference (RNAi) can be exploited experimentally to effectively and reversibly silence nearly any gene target not only *in vitro* but also in live mice. Here, we take advantage of these powerful technologies and combine both tet-inducible CRISPR-Cas9 and inducible RNAi-mediated gene silencing to develop animal models in which both

de novo disease pathogenesis can be induced by Cas9-mediated genome editing and therapeutic strategies assessed downstream via RNA interference-mediated gene silencing. By using this combination of CRISPR/Cas9 and RNAi technologies, we are able to not only model disease, but also mimic drug therapy in the same mice, giving us advanced capabilities to perform preclinical studies *in vivo*. Using our robust flexible system, we have created a cost-effective and scalable platform for the production of complex genetically engineered mouse models with RNAi silencing of nearly any gene - mice with enormous predictive power that will shape our development of better tolerated therapies.

M281 CRISPR/Cas9 Genome Editing Pipeline for Mice and Rats. *Thom Saunders*, Wanda Filipiak, Galina Gavrilina, Anna LaForest, Corey Ziebell, Michael Zeidler, Elizabeth Hughes. University of Michigan, Ann Arbor, MI.

CRISPR/Cas9 is a RNA guided nuclease that produces double strand breaks in DNA molecules and chromosomes. Mouse and rat zygotes with chromosome breaks may repair breaks with non-homologous endjoining (NHEJ) or homology directed repair (HDR) pathways. Repair NHEJ by often produces deletions and insertions in critical regions for gene expression that causes gene knockouts as a result. When the zygote copies new DNA sequence from a DNA donor template during HDR a new DNA sequence will be expressed from the targeted locus. Genes for the CRISPR/Cas9 pipeline are identified by investigators and the Transgenic Core designs sgRNA targets in critical regions with online algorithms. High scoring sgRNAs are cloned for *in vitro* sgRNA transcription. Activity of sgRNA is validated in two steps: 1) cleavage of PCR templates *in vitro* after mixture with Cas9 protein and 2) microinjection into mouse zygotes and testing blastocysts for NHEJ repair. Rat gene sgRNAs are tested by transfection of rat cells and identification of NHEJ mutations. Results will be presented on 1) producing gene knockouts in mouse and rat strains, 2) introducing coding SNPs knockins with oligonucleotide in mice and rats, 3) producing reporter gene knockins in mice and rats, 4) producing floxed genes with a novel one-cut strategy in mice, and 5) reporter gene knockins into the *Gt(ROSA)26Sor* locus. Analysis shows that mosaic founders occur frequently. Mutations observed in founders vary from deletion/insertion of a few nucleotides to the deletion of several hundred base pairs. These patterns are observed in gene knockouts in both mouse and rat models. The efficiency of CRISPR/Cas9 targeting was lower in inbred C57BL/6J mice than in mixed genetic backgrounds (C57BL/6 and SJL). NHEJ inhibitors such as SCR7 were ineffective in a series of reporter knockin experiments. Experiments are underway to determine if the high fidelity Cas9 system (Cas9HF1) is as efficient as the wild type Cas9 endonuclease. Gene targeting with CRISPR/Cas9 is highly efficient, we guarantee the production of mouse and rat gene model knockouts with reagents designed and cloned in our Core facility. The efficiency of oligonucleotide knockins is lower, the majority of SNPs succeed. ROSA26 knockins are also efficient. The introduction of complex alleles such as multi-reporter knockins (e.g. iCre-P2A-mCherry) are least efficient and cannot always be guaranteed. Compared to preceding technologies, CRISPR/Cas9 technology has significantly increased access to mouse and rat genomes for the generation of biomedical research models.

M282 *Easy*-(*Isi*)-CRISPR; a method to efficiently knock-in long DNA inserts. *CB Gurumurthy*[1], Rolen Quadros[1], Don Harms[1], Guy Richardson[2], Suzanne Mansour[3], Masato Ohtsuka[4]. 1) University of Nebraska Medical Center, Omaha, NE; 2) University of Sussex, UK; 3) University of Utah; 4) Tokai University, Japan.

CRISPR/Cas9 technology efficiently produces *indels* (*in*sertions or *del*etions) and inserts short sequences when single stranded oligonucleotides are used as repair templates. However, insertion of longer stretches using double stranded DNA (dsDNA) templates is proven to be less efficient and challenging. There are a few reports that employed strategies to enhance homology directed repair mechanism of longer dsDNA templates. Here we describe a novel strategy called Isi-CRISPR (***I***vTRT-***s***sDNA-***i***nsertion-CRISPR; pronounced *Easy*-CRISPR) that uses *in vitro* synthesized ssDNAs up to 1.6 kb and show that they get inserted at the Cas9 cut sites very efficiently.

M284 An inducible dominant negative allele of *Sox10* models neurocristopathy deficits characteristic of PCWH patients. *M. Southard-Smith*[1], M. Halaka[1], N. J. Lawler[1], J. M. DeKeyser[1], J. Corpening Rosebrock[1], S. Arpag[1], J. Li[1], A. Economides[2], A. Braun[3], K. H. Schäfer[3], K. Boyd[1]. 1) Vanderbilt University Medical Center, Nashville, TN; 2) Regeneron Pharmaceuticals Inc., Tarrytown, NY; 3) University of Applied Sciences Kaiserslautern, Zweibrücken, RLP, GER.

Sox10 is a transcription factor that is essential for development of a wide range of cell fates including oligodendrocytes and neural crest-derived neurons and glia of the peripheral and enteric nervous systems, melanocytes in the skin, craniofacial bones, teeth, and the adrenal medulla. Investigating *Sox10* function in these distinct lineages has been difficult because simple gene knockouts cause complete loss of gene expression in early neural crest leading to embryonic lethality. Efforts to temporally ablate *Sox10* through gene knockout strategies have been hampered by kinetics of mRNA and protein decay. We have generated and characterized a COnditional INducible ("COIN") dominant negative allele of *Sox10* in mice as a novel tool for temporal and cell type specific analysis of gene function. Mice bearing a COIN cassette in the *Sox10* locus appear normal until Cre action flips a fluorescently tagged dominant negative *Sox10* isoform into the coding frame of exon four. Our characterization of this new allele indicates that the COIN cassette functions in a dominant negative fashion and fluorescently labels neural crest derivatives following Cre action. Crosses of *Sox10-COIN* mice with Cre drivers produce mutant progeny (B6J.B6N-*Sox10*$^{tm1.1Sout}$ or *Sox10-COIN*$^{INV+}$) that exhibit hypopigmentation, deficits in central and peripheral glia as well as gastrointestinal phenotypes. *Sox10-COIN*$^{INV+}$ pups show spotting accompanied by coat color variegation. We have named this new allele *"Merle"* based on the coat color variegation similarity to blue merle dogs. At P10 *Merle* pups exhibit peripheral limb weakness and instability in tracking. By P15 *Merle* mutants are severely affected with motor deficits, circling, and difficulty in righting. Histological and functional analysis of *Merle* tissues has identified central and peripheral

neuropathy that is consistent with phenotypes reported in patients afflicted by the complex neurocristopathy called Peripheral Demyelinating Neuropathy, Central Dysmyelinating Leukodystrophy, Waardenburg Syndrome, and Hirschsprung Disease (PCWH). The availability of this new allele will provide mechanistic insight into the pathology suffered by PCWH patients and permit manipulation of distinct neural crest lineages.

M285 Alpha-synuclein, the cause of Parkinson's disease, has a vital function in aged mice. *D. E. Cabin*, Dan Zou. McLaughlin Research Institute, Great Falls.

Parkinson's disease is the second most common neurodegenerative disease in humans.

It is slowly progressive, affecting many regions of the nervous system, including nigral dopaminergic neurons, and can eventually lead to dementia in addition to the well known motor symptoms. Alpha-synuclein (SNCA) is the protein responsible for Parkinson's disease. SNCA can convert to a toxic form and that toxic form propagates through the nervous system in a templated manner, dependent on endogenous production of SNCA. While the precise nature of the toxic form is not known, this mechanism indicates that SNCA is a prion. One potential therapeutic strategy would be reduction of endogenous SNCA production. Lowering the endogenous levels of SNCA would likely slow disease progression. However, the normal role of SNCA is not completely understood, so reducing SNCA levels might have unintended consequences. We have recently found that mice null for *Snca*(129S6-*Scna*^{tm1Nbm}/*Snca*^{tm1Nbm}) have a significantly shorter lifespan than WT mice, indicating that SNCA function is important in aging. This difference in lifespan appears at about 400 days and shortens overall lifespan by about 200 days. Conversion of SNCA to a toxic form in humans may prevent it from performing some needed role in aging, thus contributing to disease.

We performed a sensitized ENU mutagenesis screen using *Snca* null mice to better understand the protein's normal function. One sensitized mutation was identified after screening 125 pedigrees. This mutation occurred in the gene for ATP7A, a trans-Golgi copper transporter. Female mice carrying the X-linked mutation have a significantly higher rate of early death when they lack *Snca* than when the *Atp7a* mutation is on the *Snca* WT background. In humans, mutations in *ATP7A* cause Menkes disease. Linking SNCA and ATP7A genetically indicates that SNCA has a role in the trans-Golgi compartment. Immunofluorescence on both brain sections and on primary neurons derived from a) 129S6;B6J-*Atp7a*^{m1Decn}/*Y Snca+/+*, b) 129S6;B6J-*Atp7a*^{m1Decn}/*Y Snca-/-*, c) 129S6;B6J-*Atp7a+/Y Snca+/+*, d) 129S6;B6J-*Atp7a+/Y Snca-/-* mice indicates that SNCA is found in the trans-Golgi compartment, co-localizes with ATP7A, and seems to play a role in proper localization of ATP7A to axons. We are now examining brains of aged mice to determine aging affects SNCA and ATP7A subcellular localization, and whether lack of SNCA affects the trans-Golgi compartment during aging. Golgi fragmentation has been observed in Parkinson's disease, but whether this is due to SNCA toxicity or whether the loss of SNCA function plays a role is unknown.

M286 Aberrant DNA binding by mutant (E339D) KLF1 induces upregulation of embryonic β-globin in adult mice. *D. M. Nebor*[1], R. R. Robledo[1], A. C. Perkins[2], K. Gillinder[2], J. H. Graber[1], D. Gatti[1], V. Philip[1], J. J. Bieker[3]. 1) The Jackson Laboratory, Bar Harbor, ME; 2) University of Queensland, Woolloongabba, Australia; 3) Mount Sinai School of Medicine, New York, NY.

The KLF1 transcription factor regulates nearly all aspects of erythroid differentiation including heme synthesis and globin regulation. Previously we showed that the inbred mouse model *Nan* (neonatal anemia) carries a missense mutation (E339D) in the second zinc finger of KLF1 that causes severe lifelong anemia in heterozygotes accompanied by a striking failure of hemoglobin switching. Embryonic *Hbb-bh1* globin expression is significantly upregulated in *Nan* E14.5 fetal liver (FL) and in adult spleen. In humans elevation of fetal hemoglobin (HbF) ameliorates the severity of sickle cell disease and b-thalassemia. To examine the mechanisms of *Hbb-bh1* regulation in adult *Nan*, we analyzed the global erythroid transcriptome by RNA-seq in wild type (WT) and *Nan* E14.5 FLs. Only 18% of upregulated and 52% of downregulated genes in *Nan* overlap known KLF1 target genes. Moreover, just 3% of upregulated *Nan* genes overlap genes normally activated by KLF1. We also analyzed the transcriptome of sorted erythroid precursors (pro, basophilic, polychromatophilic and orthochromatic erythroblasts) in adult spleens. Together the RNA-seq data show that extensive ectopic gene expression occurs in *Nan.* To analyze the DNA binding of KLF1^{Nan} vs. WT, we performed ChIP-seq in K1-ER and K1-NanER cell lines. Results show aberrant DNA binding, both absent and ectopic, by KLF1^{Nan}. To identify potential genetic modifiers of *Hbb-bh1* expression, we performed expression QTL analysis of *Hbb-bh1* in two *Nan* F2 intercrosses and in an outbred high resolution mapping population, the diversity outcross (DO). Statistical analyses reveal multiple significant and suggestive *Hbb-bh1* eQTL. Among the genes present in these eQTL confidence intervals, those showing abnormal expression in *Nan* with dysregulated DNA binding by KLF1^{Nan} represent strong candidate genes for future functional anaylses as novel regulators of *Hbb-bh1* expression. A better understanding of the genetic regulation of the switch of hemoglobin is key to the identification of new drug targets for the treatment of sickle cell disease and β-thalassemia.

M287 Mutations in beta spectrin protect mice from malaria by increasing parasite susceptibility to clearance. *G. R. Burgio*[1], P. M. Lelliott[1], H. M. Huang[1], M. Dixon[2], L. Tilley[2], B. J. McMorran[1], S. J. Foote[1]. 1) The Australian National University, Canberra, ACT, AU; 2) University of Melbourne, Melbourne, VIC, AU.

Malarial parasite resistance to all known antimalarial drugs is now the norm. Parasites develop resistance through modification of both target and intra-parasitic drug concentrations. We have developed a strategy to develop new therapies that will bypass both these mechanisms of resistance. ENU mutagenesis is used to introduce mutations into the germline of mice that are otherwise susceptible to murine malaria. Mice carrying protective mutations will survive a malarial challenge whereas all other mice will succumb. The genes harbouring the mutations are identified and assessed as potential antimalarial drug targets. At present we have identified over 40 mutations conferring resistance to malarial infection and have 100 resistant lines. Here, we propose novel mechanisms of host resistance to malaria infection. Through our dominant large scale ENU screen for abnormal red blood cell count, 2 novel mutant alleles were identified in spectrin beta (*Sptb*) gene. All of the mutants

exhibit an abnormal red blood cell count, an increase osmotic fragility and a shorter red blood cell (RBC) half-life responsible for hereditary spherocytosis disease. When challenged with the rodent malaria parasite, *P. chabaudi* and *P.berghei*, *Sptb* mutant mice were resistant showing a dramatic increase in survival. We propose that the malaria resistance of *Sptb* lines is mediated by the deformability and the increase susceptibility to red blood cells clearance from splenic macrophages. This study provides the first evidence that a mutation in *Sptb* can lead to malaria resistance in mice, and shows that splenic clearance is essential for eliminating *Plasmodium* spp within Red Blood cells.

M288 Interaction of BRCA2 and PALB2 is essential for genome stability. *S. A. Hartford*[1], R. Chittela[1], X. Ding[1], A. Vyas[1], B. Martin[2], S. Burkett[1], D. Haines[2], E. Southon[1,2], L. Tessarollo[1], S. K. Sharan[1]. 1) Mouse Cancer Genetics Program Center for Cancer Research National Cancer Institute, Frederick, MD; 2) Leidos Biomedical Inc, National Cancer Institute Frederick, MD.

Efficient DNA repair, DNA replication, and regulating cell cycle checkpoints are all essential factors in protection from genomic instability. Breast cancer 2 (*Brca2*) and partner and localizer of BRCA2 (*Palb2*) are well-known factors associated with increased risk of breast and ovarian cancers. They both have essential roles involved in DNA repair, protection of stalled replication forks, and maintenance of the cell cycle checkpoint. While these two proteins interact and have similar roles in protection of the genome, what hasn't been shown is if the interaction is critical for full functionality *in vivo*. BRCA2 and PALB2 each have their own DNA binding motifs and both can bind to RAD51, so can the protection of the genome occur even if this interaction is perturbed? To investigate the functional importance of the interaction between BRCA2 and PALB2 we created a knock-in mouse model of BRCA2. The single amino acid change (Gly25Arg) is in the highly conserved N-terminal region that interacts with PALB2. This particular mutation was previously shown to cause a decrease but not abolish this interaction. These mice vary in phenotype and tumor latency base on whether the mutation is in homozygous or hemizygous state. An additional heterozygous loss of *Palb2*$^{Gt(CG0691)Wtsi}$ results in earlier tumor formation and more severe phenotypes in the mice. At the cellular level there is an increasing amount of genomic instability with the decreasing amount of interaction between BRCA2 and PALB2. This also holds true when looking at the ability of RAD51 foci formation after damage and the protection of the DNA replication fork in times of replication stress. This series of phenotypically distinct mouse models shows the critical need for proper interaction between these two genes for protection of the genome. In addition this series of animal models will also distinguish between the protection of the replication fork verses the ability for efficient HR in terms of being able to protect against genomic instability.

M289 Pathophysiological responses to dietary patterns differ with genetic backgrounds. *William T. Barrington*[1,2], Daniel Pomp[3], Brian Bennett[3], Carolina Mantilla Rojas[1], Selene Howe[1], David Threadgill[1]. 1) Texas A&M University, College Station, TX; 2) North Carolina State University, Raleigh, NC; 3) University of North Carolina, Chapel Hill, NC.

Dietary patterns have repeatedly been shown to have profound effects on health when studied at the population level. For example, Japanese and Mediterranean diets are associated with longevity and low rates of various chronic diseases. Western diets are associated with increased risk of heart disease and certain types of cancer. However, studies evaluating dietary interventions in individuals find significant variations in responses. Much of this variation is likely because of underlying genetic differences among individuals. To determine how diet affects pathophysiological responses in different genetic backgrounds, we examined cardiometabolic-related effects of five diets (current Western diet, traditional Mediterranean diet, traditional Japanese diet, a ketogenic diet and standard mouse chow) in each sex of four inbred mouse strains (A/J, C57BL/6J, FVB/NJ, and NOD/ShiltJ) selected for their known disparate susceptibilities to cancer, diabetes, and other diseases. Mice were fed diets ad libitum for six months while undergoing a variety of clinical analyses. We found that many health-related diet responses are dependent upon genetic background including: adiposity, glucose tolerance, blood chemistry profiles, liver triglyceride storage, liver mitochondrial function, and metabolic rate. The severity and directionality of many of these diet responses differ depending on the genetic background of the individual. For example, C57BL/6J mice became obese and showed signs of cardiometabolic distress on a Western diet but maintained good health on a ketogenic diet; FVB/NJ mice had minimal fat gain and were relatively healthy on a Western diet but became obese and suffered cardiometabolic distress on a ketogenic diet. Most strains had positive health profiles on the Japanese diet, while the health of A/J mice differed little across diets. Mouse strains differed as to which diets were optimal or suboptimal, suggesting that human individuals likely have a specific diet for optimal health based upon their unique genetic makeup. These results call into question the categorization of diets as good or bad and emphasize the need to evaluate dietary efficacy on an individual level. Follow-up studies are investigating the genetic factors underlying the different diet responses with the ultimate goal of allowing accurate prediction of diet response in genetically diverse human individuals.

M290 *Xist* RNA, its interactome, and consequences of their disruption in vivo. *Jeannie Lee*[1*], Lin Yang[1], James Kirby[2]. 1) HHMI, Harvard Medical School, Massachusetts Gen Hosp, Boston, MA; 2) Beth Israel - Deaconess Medical Center, Harvard Medical Schoo, Boston, MA.

Epigenetic regulation often occurs at the interface between RNA and chromatin. Long noncoding RNAs (lncRNAs) have a special role in epigenetic regulation because they are able to serve as barcodes that target protein complexes to specific genomic addresses. The inactive X chromosome serves as an excellent model by which to investigate the function of lncRNA. My presentation will focus on how lncRNAs collaborate with protein factors to regulate X-chromosome counting, allelic choice, and the spread of silencing along the inactive X chromosome. I will also discuss the consequences of losing those interactions in the context of development.

M291 Allelic imbalance is a prevalent and tissue-specific feature of autosomal and X-linked genes in F1 hybrid mice. *S. F. Pinter*[1,2,3,7], D. Colognori[2,3,4,7], B. J. Beliveau[3], R. I. Sadreyev[2,3], B. Payer[2,3,5], E. Yildirim[2,3,6], C. T. Wu[3], J. T. Lee[2,3,4,8]. 1) UConn Health, Institute for Systems Genomics, Farmington, CT; 2) Massachusetts General Hospital, Boston, MA; 3) Harvard Medical School, Boston, MA; 4) Howard Hughes Medical

Institute, Chevy Chase, MD; 5) Centre for Genomic Regulation, Barcelona, Spain; 6) Duke University, School of Medicine, Durham, NC; 7) co-first authors; 8) corresponding author.

In mammals, several classes of monoallelic genes have been identified, including those subject to X-chromosome inactivation (XCI), genomic imprinting, and random monoallelic expression (RMAE). However, the extent to which these epigenetic phenomena are influenced by underlying genetic variation is unknown. We performed a systematic classification of allelic imbalance in mouse hybrids derived from reciprocal crosses of divergent strains. We observe that deviation from balanced biallelic expression is common, occurring in ~20% of the mouse transcriptome in a given tissue. Allelic imbalance attributed to genotypic variation is by far the most prevalent class and typically is tissue-specific. However, some genotype-based imbalance is maintained across tissues and is associated with greater genetic variation, especially in 5' and 3' termini of transcripts. We further identify novel random monoallelic and imprinted genes and find that genotype can modify penetrance of parental origin even in the setting of large imprinted regions. Examination of nascent transcripts in single cells from inbred parental strains reveals that genes showing genotype-based imbalance in hybrids can also exhibit monoallelic expression in isogenic backgrounds. This surprising observation may suggest a competition between alleles and/or reflect the combined impact of *cis*- and *trans*-acting variation on expression of a given gene. We also identify tissue-specific genes that escape XCI, and share some surprising and speculative insights from integrating these allele-specific expression results with other epigenomic data.

M292 *Vive la difference*: zooming in on sex-specific differences in mouse embryonic stem cells. *N. Engel*, R. Werner, B. Schultz, J. Madzo, J. Jelinek. Temple University, Philadelphia, PA.

Mortality rates in males are higher than in females at every age, including as newborns. Although sexual dimorphisms are usually attributed to hormonal influences, differences observed at early embryonic stages can't be accounted for in this way. For example, male embryos have a higher growth rate at preimplantation stages, before overt sexual differentiation and exposure to sex hormones. X inactivation, a drastic epigenetic event exclusive to females, likely affects the embryonic transcriptome and epigenome in a sex-specific manner. Thus, male and female genomes are epigenetically poised for their divergent pathways early on. To determine whether there is differential expression at preimplantation stages, we derived male and female mouse embryonic stem (ES) cell lines and performed RNA-sequencing. When XY and XX cell lines were compared, over 400 coding genes were differentially expressed ($\alpha < 0.01$). A substantial number of these are transcription factors and epigenetic enzymes that are predicted to be dosage sensitive, indicating that there are regulatory differences between male and female embryos that depend solely on their chromosomal composition. In addition, we found more than 300 non-coding RNAs that were sex-biased ($\alpha < 0.01$). RNA-seq results were validated by qPCR and effects of differentially expressed transcription factors were confirmed with luciferase assays. To determine whether these expression differences translated into epigenomic differences, we conducted focused chromatin immunoprecipitation analyses and observed significant sex-dependent variation in chromatin accessibility in specific genes. We are exploring whether these sexual dimorphisms predict distinctions in response to environmental signals and whether they foreshadow sex-specific health-related outcomes after birth. Our results will have implications in understanding the developmental origins of disease, will impact disease treatment and stratification and, importantly, may have significance in the field of regenerative medicine. Furthermore, understanding sex biases in transcription and epigenetic status will provide insights into sex differences in susceptibilities to and protection from diseases.

M293 Genetic control of the epigenetic landscape. *Christopher L. Baker*[1], Guruprasad Ananda[1], Michael Walker[1], Catrina Spruce[1], Karl W. Broman[2], Petko Petkov[1], Greg Carter[1], Kenneth Paigen[1]. 1) The Jackson Laboratory, Bar Harbor, ME, USA; 2) The University of Wisconsin-Madison, Madison, WI, USA.

Cellular differentiation and numerous biological functions are controlled by a wide variety of regulatory elements associated with characteristic epigenetic modifications. Although a variety of proteins are known to act as writers, readers, and erasers of these marks, we know little about the organizing principles behind the systems regulating the establishment and maintenance of this epigenetic landscape. Understanding how these marks are controlled, and ultimately the ability of cells to differentiate and regulate their functions, is a fundamental and open question in biology. As a model to explore these issues, we have leveraged the strength of mouse genetics to understand how natural genetic variation impacts these processes. Studying levels of H3K4me3, an epigenetic mark associated with promoters, enhancers and recombination hotspots, we compared the genomes of C57BL6/J and DBA2/J mice finding considerable differences in activity of individual H3K4me3 sites in spermatocytes. Haplotype-specific analysis in F1 hybrids showed evidence of trans-control at numerous sites where the phenotype at the site did not coincide with the genotype of the parent. To identify the underlying genetic control, we measured H3K4me3 levels at 72,859 sites in a mapping population of 32 BXD recombinant inbred lines, identifying 6,868 QTL at FDR < 0.1. Most QTL map proximally, indicating control of H3K4me3 levels in cis. There were also1,262 trans-regulated sites, with five major QTL controlling greater than 55 sites each, collectively regulating 62% of all trans-regulated sites. The largest trans QTL on Chr 13 controls 452 sites. Importantly, trans-regulated H3K4me3 sites are clustered in domains of 1-10 Mb (R-scan statistic $p < 0.001$), indicating that trans control involves regional higher order chromatin organization rather than acting on individual H3K4me3 sites. In agreement with this, we find that the same QTL can affect both recombination hotspots where H3K4me3 is deposited by the enzyme PRDM9, and at promoters and enhancers, which are methylated by distinct enzyme systems. Finally, comparing spermatocytes with hepatocytes, we find evidence that these systems are cell and tissue specific, suggesting different systems may play key roles in establishing or maintaining differentiation. Together, these QTL constitute an integrated system controlling the epigenetic landscape in which each QTL controls multiple domains scattered across the genome. Their existence obviously raises questions of the identity of the genes underlying these QTL, their mechanism of action and their roles in regulating cellular differentiation and function.

M294 Genetic Variation Mediates the Epigenetic Response to Corticosteroids in Mice. *Gregory W. Carter*, Catrina Spruce, Robyn Ball, Wendy Pitman, Narayanan Raghupathy, Anna L. Tyler, Michael Walker, Kenneth Paigen, Petko M. Petkov. The Jackson Laboratory, Bar Harbor, ME.

Epigenetic changes such as histone modifications and DNA methylation can modulate transcript expression through chromatin state reorganization. Natural genetic variation potentially alters these modifications, providing a molecular mechanism for many of the abundant cis-acting gene expression quantitative trait loci (eQTL) that associate local genetic variation with differences in transcript levels. Importantly, such variation may mediate the individual response to drug treatments. However, the effects of genetic variation on regulatory regions and the extent to which alterations in DNA methylation and local chromatin configuration play a role in them have not been extensively studied. We use purified hepatocytes from a set of nine diverse mouse strains, including the founders of the Collaborative Cross and DBA/2J, to study how genetic variation affects baseline epigenetic marks as well as the response to the glucocorticoid dexamethasone. By combining RNA-seq, bisulfite DNA-seq, and ChIP-seq assays for H3K4me1, H3K4me3, H3K27me3, and H3K27ac, we obtained a detailed view of the impact of genetic variation on both epigenetic marks and transcript abundances. We found that strain-specific variation in both gene expression and epigenetic marks is abundant, and is much greater than the consequences of dexamethasone treatment in terms of both number of loci affected and the magnitude of effects. Furthermore, the effect of treatment varies substantially across mouse strains, both at the genetic and epigenetic level, providing evidence of coordinated variation in molecular responses to a common immunosuppressant. Finally, our results provide insights on the extent to which local eQTL detected in mouse intercross populations such as the Diversity Outbred and BxD may be due to cis-acting genetic variation in promoter and enhancer activities.

M295 EZH2 Isoforms Differentially Regulate the Function of Polycomb Repressive Complex 2. *W. Mu*, J. Starmer, D. Yee, T. Magnson. University of North Carolina at Chapel Hill, Chapel Hill, NC.

Polycomb-repressive complex 2 (PRC2) catalyzes the methylation of histone H3 Lys27 (H3K27) and functions as a critical epigenetic regulator of both stem cell pluripotency and somatic differentiation. EZH1 and EZH2 are enzymatic subunits of PRC2, the latter of which is encoded by alternative splice isoforms. To elucidate how EZH variants regulate PRC2 in establishment of H3K27 methylaiton during cell differentiation, we analyzed the alteration of di- versus tri-methylation of H3K27 in spermatocytes during meiotic prophase I. We found that H3K27me2 levels were strikingly elevated across all nuclei during the zygotene-to-pachytene stage transition, which occurs along with upregulation of expression of *Ezh2*. In contrast, there was no significant increase in H3K27me3 during meiotic progression. Interestingly, a new *Ezh2* isoform, where exon 14 is deleted due to alternative splicing, was dramatically increased in meiocytes compared to mitotic germ cells. However, the *Ezh2* isoform containing exon 14 (*Ezh2- ex14*) downreguated as meiosis was initiated. We observed that expression of *Ezh2-ex14* isoform upregulated during mitosis in rapidly dividing mouse embryonic fibroblasts. These results suggest that EZH2 isoforms may function differently in non-dividing cells such as spermatocytes undergoing differentiation during meiosis versus mitotically replicating cells such as mouse embryonic fibroblasts and that these distinct isoforms may determine the choice of di- versus tri-methylation of H3K27.

M296 The function of the histone demethylase KDM1A (LSD1) in Tau mediated neurodegeneration. *David Katz*, Michael Christopher, Dexter Myrick, Amanda Engstrom, Rohitha Moudgal. Dept. of Cell Biology, Emory University, Atlanta, GA.

Alzheimer's disease (AD) is the most common form of dementia that occurs during aging. AD is associated with the pathological aggregation of Ab and pTau. Nevertheless, it remains unclear how these protein aggregates lead to neuronal cell death in AD. Here we implicate a potential epigenetic step in AD. Data from our lab demonstrates that the histone demethylase KDM1A/LSD1 is mislocalized with aggregated pTau in AD cases. In addition, we find that loss of KDM1A systemically in adult mice is sufficient to recapitulate many aspects of AD, including widespread neuronal cell death in the hippocampus and cortex, learning and memory defects, and global gene expression changes that match AD cases. Surprisingly, in degenerating hippocampal neurons, we also detect the inappropriate re-expression of stem cell genes. These data raise the possibility that aggregated pTau leads to neuronal cell death in AD by interfering with the continuous requirement for KDM1A to epigenetically repress transcription associated with alternative cell fates. To further investigate the potential involvement of KDM1A in the AD pathway, we also removed one copy of *Kdm1a* from Tg(Prnp-MAPT*P301S)PS19Vle (P301S Tau) mice, which contain a transgene overexpressing an aggregation prone form of MTAP (Tau). If pTau leads to neurodegeneration by interfering with KDM1A, we would expect these mice to exhibit a faster, more severe neurodegeneration phenotype. Remarkably, our preliminary results indicate that partial loss of KDM1A enhances the Tau-mediated neurodegeneration in this mouse model. These results indicate that it may be possible to target KDM1A therapeutically to block the progression of AD in patients.

M297 Engineering the Cancer Genome. *Tyler Jacks*. Koch Institute for Integrative Cancer Research, HHMI, MIT, Cambridge, MA.

M298 Genetic inhibition of MTOR during thymic Pre-T LBL development delays tumorigenesis and points to the IRF4-CDK6 pathway as a potential target in the treatment of T-ALL/LBL. *B. A. Mock*[1*], J. M. Gary[1,2], J. K. Simmons[1], J. Xu[3], S. Zhang[1], N. Watson[1], B. Gamache[1], K. Zhang[1], A. L. Kovalchuk[4], A. M. Michalowski[1], M. Kiupel[2], S. Gaikwad[1], W. Dubois[1], J. Testa[1]. 1) CCR, NCI, NIH, Bethesda, MD; 2) Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI; 3) Fox Chase Cancer Center, Philadelphia, PA; 4) NIAID, NIH, Rockville, MD, USA.

The PI3K/AKT/MTOR pathway is frequently activated in T-cell acute lymphoblastic leukemia/lymphoma (T-ALL/LBL). To model inhibition of this pathway in lymphoma, mice with T-lymphocyte-specific, constitutively-active AKT (Tg(Lck-Akt2*)#Test, Lck-MyrAkt2) were crossed to mice

with genetically reduced MTOR expression (*Mtor*^{tm1Lgm} knock-down, KD). Mice with genetic reduction of MTOR had increased survival relative to wild type MTOR mice (average survival of 24 versus 14 weeks, respectively), though both groups ultimately developed thymic pre-T-cell lymphoblastic leukemia/lymphoma (pre-T LBL). A similar increase in survival was observed when MTOR wild type Lck-MyrAkt2 mice were treated for 8 weeks with the rapamycin analog, everolimus, an inhibitor of the mTORC1 complex. Transcriptional profiling of wildtype (WT) and MTOR KD thymic lymphomas identified cyclin dependent kinase, *Cdk6*, as one of the most down-regulated genes during tumorigenesis in the Lck-AKT, MTOR KD tumors; its expression was the same in WT and KD pre-tumor thymocytes. The interferon regulatory transcription factor, *Irf4*, was identified as an upstream regulator; protein levels of IRF4 were down-modulated in both pre-tumor thymocytes and pre-T LBL cells in the KD mice, compared to levels in WT littermates. Rescue experiments have confirmed the relationship between IRF4 and CDK6. Pharmacologic inhibition of MTOR in tumor cells also decreased CDK6 protein levels, further suggesting a mechanistic relationship in this tumor type. Combination treatment with the MTOR inhibitor rapamycin and the CDK4/6 inhibitor palbociclib cooperatively decreased the overall viability and signaling downstream of drug targets in human T-ALL/LBL cell lines. Further, the combination of palbociclib and rapamycin decreased tumor size and proliferation in nude mice with Lck-Akt/MTOR WT tumor flank transplants, and significantly increased survival in an intravenous transplant model of disseminated leukemia compared to single agent treatments, suggesting the potential for this drug combination in treating T-ALL/LBL.

M299 Adenoma Susceptibility Modulated by Variable Complex Gut Microbiota in a Rat Model of Familial Colon Cancer. *Susheel Busi*, Aaron Ericsson, Taybor Parker, Craig Franklin, Elizabeth Bryda, James Amos-Landgraf. University of Missouri-Columbia, Columbia, MO.

Mechanisms of colonic tumor initiation suggest that cancer can develop through multiple genetic and epigenetic pathways. Human epidemiologic studies have shown the presence of cancer is associated with changes in the complex gut microbiota (GM). To determine if differences in the complex GM directly cause differences in cancer susceptibility, we used complex microbiota targeted rederivation (CMTR) to rederive isogenic embryos of the F344/NTac-*Apc*^{Pirc}*/+ (Pirc)* rat model of familial adenomatous polyposis, using three different strains of surrogate dams (F344/NHsd (*F344*), LEW/SsNHsd (*LEW*), and Crl:SD (*SD*)) each harboring distinct gut microbiota. Fecal samples from the rederived pups were collected from weaning up to 180 days. The GM composition was characterized to the operational taxonomic unit (OTU) level by extracting bacterial DNA from fecal material and sequencing the 16S rRNA gene V4 hypervariable region on the Illumina MiSeq platform. Adenoma development was also monitored longitudinally via colonoscopy and tumor multiplicity was determined at 6 months.

We found that the GM varied between dams, and that the pups' microbiota resembled their surrogates by 1.5 months. Two rats with the LEW GM did not develop any colonic tumors, decreasing the Pirc phenotype penetrance from 100% to 87%. All rats with this GM also had a significantly reduced colonic tumor burden compared to both F344 GM ($p<0.001$) and SD GM ($p<0.05$). The relative abundance of certain OTUs including family Peptococcaceae and *Akkermansia muciniphila* were positively correlated with tumor multiplicity in the F344 GM ($p<0.05$). A previously reported sex bias in colonic tumor burden was also confirmed with males showing more adenomas than females ($p<0.05$). To assess functional changes associated with variation in GM, PICRUSt (Phylogenetic Investigation of Communities by Reconstruction of Unobserved States) was used and showed elevated expression of H_2S-related bacterial genes in the LEW GM.

To assess whether tumors from rats with diverse GM differed in loss of heterozygosity (LOH), we used a quantitative allele-specific pyrosequencing assay to determine the allelic ratio of the genomic *Apc*^{Pirc} loci in colonic tumors. Approximately 70% of tumors from rats with F344 GM underwent LOH with 30% tumors maintaining heterozygosity of the *Apc* allele, consistent with previous reports. Interestingly, rats with SD and LEW GM showed 100% and 96% LOH respectively, suggesting a possible link between differing complex microbiota and loss of the wildtype Apc allele. Our study provides new insight into the role of gut microbiota as a modulator and predictor of disease phenotype in this rat model.

M300 The aggressive prostate cancer susceptibility gene *HIST1H1A* is a modulator of androgen receptor signaling and epithelial to mesenchymal transition. *K. Williams*[1], M. Lee[1], Y. Hu[2], J. Andreas[1], S. Zhang[1], N. Crawford[1]. 1) NHGRI/NIH, Bethesda, MD; 2) NCI/NIH, Rockville, MD.

In 2016, approximately 190,000 new prostate cancer (PC) cases will be diagnosed, and over 26,000 men will succumb to PC. Presently, there is an urgent need to more precisely identify men at risk for aggressive PC. This study aims to characterize how germline variation modulates susceptibility to 'neuroendocrine (NE) differentiation', which is a marker of aggressive PC. Our earlier study identified aggressive PC susceptibility genes using the C57BL/6-Tg(TRAMP)8247Ng/J (TRAMP) mouse model of NE PC. We performed quantitative trait locus (QTL) mapping in transgene-positive (TRAMPxNOD/ShiLtJ) F2 intercross males (n=228), and expression QTL mapping using primary tumor microarray data (n=126) identified 35 aggressive PC candidate genes. Furthermore, *in silico* analysis identified *HIST1H1A*, which encodes the linker histone H1.1, as having an expression level associated with patient outcome in a human PC gene expression dataset, and harboring a SNP associated with lymph node metastasis in the PC genome-wide association study. Ectopic expression of *HIST1H1A* in the aggressive, androgen receptor (AR)-negative human prostate PC3-Luc cell line suppressed tumor growth in a xenograft flank assay (avg. tumor vol. = 311+/-69 mm^3 vs. 565+/-193 mm^3 for controls; P=1.01x10^{-4}), and reduced dissemination in a systemic metastasis assay (avg. flux=4.45x10^8 vs. 1.01x10^9 for controls; P=0.035). Conversely, in the AR-positive LNCaP cell line, ectopic expression of *HIST1H1A* enhanced tumor growth. Microarray analysis of the latter cell lines revealed that over 2,600 transcripts were significantly dysregulated in response to *HIST1H1A* over-expression (fold change +/-1.5, false discovery rate < 0.05). Ingenuity Pathway Analysis revealed that both AR signaling and epithelial to mesenchymal transition (EMT) were significantly impacted. Quantitative RT-PCR indicated that higher *HIST1H1A* levels were associated with suppression of epithelial gene expression (e.g., *KRT18*, *TJP1*) and activation of mesenchymal genes (e.g., *SNAI2*, *VIM*). Immunoblot analysis revealed suppression of long-form AR expression and activation of the aggressive disease associated AR-V7 splice variant. Collectively, these data indicate that *HIST1H1A* affects aggressive PC by modulating AR signaling and EMT. Ongoing work involves ATAC-seq analysis to determine how *HIST1H1A* dysregulation

impacts PC-specific chromatin structure, as well as CRISPR/Cas9 knockout of *Hist1h1a* in mice. These data demonstrate the use of systems genetics to provide insights into how hereditary variation influences aggressive PC susceptibility.

M301 Polymorphisms in the *Arntl2* promoter affect metastatic susceptibility in estrogen-receptor negative breast cancer. *K. W. Hunter*, N.-H. Ha. NCI, Bethesda, MD.

Breast cancer is the leading incident of cancer and the second-leading cause of cancer-related deaths in women with the majority dying from metastatic disease. Previous studies have demonstrated the importance of inherited polymorphisms in the progression of breast cancer metastasis. In this study, we used a mouse cross between the metastatic mammary tumor model MMTV-PyMT and MOLF/EiJ to identify the circadian transcription factor *Arntl2* as a metastasis modifier in estrogen receptor (ER)-negative breast cancer. Sequence analysis of MOLF/EiJ demonstrated that non-synonomous substitutions of *Arntl2* existed between MOLF/EiJ and MMTV-PyMT mice. However, modulation of expression levels of *Arntl2* signifcantly affected metastastic capacity in multiple mammary tumor cell lines indicating that transcriptional levels play an important role in metastatic progression. Furthermore, implantation of wild type tumor cells into *Arntl2* knockout mice demosntrated that the effect of *Arntl2* on metastasis is a tumor cell intrinsic phenotype. To identify putative causative eQTL variants that modulate *Arntl2* expression levels DNase hypersensitivity site (DHS) analysis was performed. This analysis revealed 13 single nucleotide polymorphisms (SNP) in the proximal promoter region that potentially affect transcriptional activity. CRISPR/Cas9-mediated substitution of the MOLF/EiJ polymorphic promoter allele reduced *Arntl2* expression and metastatic capacity of the 4T1 metastatic mammary tumor cell line, as predicted. Taken in toto, these results provide strong evidence that the expression levels of the circadian rhythm gene *Arntl2* plays an important role in the predisposition to the development of mammary tumor pulmonary metastases.

M302 Glioma modeling with MADM, a mouse genetic mosaic system, revealed cell competition as the mechanism that enables inevitable malignant progression. *Hui Zong*, Phil Gonzalez, Jungeun Kim, Guoxin Zhang. University of Virginia, Charlottesville, VA.

Understanding tumor initiation is critical for developing early detection and cancer prevention strategies. However, this problem has been virtually impossible to study because pre-malignant mutant cells are indistinguishable from their normal counterparts. To overcome this hurdle, our lab uses a mouse genetic system termed Mosaic Analysis of Double Markers (MADM) that, from a non-labeled mouse heterozygous for a tumor suppressor gene (TSG), generates GFP-labeled TSG-null cells and RFP-labeled sibling wildtype cells. The sparseness of mutant cells due to the low frequency of *inter*-chromosomal recombination closely mimics the clonal origin of human cancer, and the definitive correlation between color and genotype greatly facilitate the analysis of the earliest tumorigenic events. In particular, **increased ratio of green to red cell numbers (G/R ratio) serves as the clear indication of initial expansion of mutant cells**. Malignant glioma is the deadliest type of cancer in the brain. One devastating fact is the inevitable progression of benign grade II tumors into full malignancy within a few years. Previously our lab identified oligodendrocyte precursor cells (OPCs) as its cell-of-origin because MADM revealed a massive expansion of pre-malignant mutant OPCs (G/R ratio > 100) long before malignant transformation. Surprisingly, the overall OPC density barely changed in the mutant brain, suggesting that **the pre-malignant expansion of mutant OPCs was achieved at the cost of WT OPCs**. Using *in vivo* time course analysis and *in vitro* co-culture experiments, we determined that the competition is mediated via active killing of WT OPCs by mutant ones. These observations well explain the inevitable progression of glioma since any individual OPC gaining an advantageous mutation would outcompete less fit ones. By repeating this process, a mutant OPC would eventually gather all necessary mutations for the full-blown transformation. This finding also predicts the unavoidable failures with cytotoxic treatment methods because they merely provide selective pressure on the evolutionary process of the tumor mass, which eventually lead to the enrichment of most resistant tumor cells. Therefore, an effectiveness treatment must deal with cell competition between mutant and WT OPCs. **In a proof-of-principle experiment, we used a genetic model to remove the competitiveness of mutant OPCs, and successfully blocked glioma formation.** Different from conventional studies that are mainly focused on cell intrinsic gene functions during tumorigenesis, MADM enabled our discovery of non-cell-autonomous mechanism for glioma progression, which should lead to completely novel therapeutic strategies.

M303 Host-pathogen genetic interactions drive outcome to tuberculosis in the Collaborative Cross. *Clare Smith*[1], Martin Ferris[2], Fernando Pardo Manuel de Villena[2], Robert Williams[3], Richard Baker[1], Christopher Sassetti[1]. 1) UMASS Medical School, Worcester, MA, USA; 2) Department of genetics, UNC Chapel Hill, NC, USA; 3) 3Department of Anatomy and Neurobiology, University of Tennessee Health Sciences Center, Memphis, TN, USA.

The complex interplay between host and pathogen determines if an individual controls infection or progresses to disease. While abundant evidence suggests that genetic diversity contributes to the variety of outcomes, the combined effect of variation in the host and pathogen remains unclear. We developed a “dual-genome” system to unravel genetic interactions between *Mycobacterium tuberculosis (Mtb)* and its mammalian host that drive outcome to infection. Host variation was modeled using a collection of ~100 recombinant inbred mouse strains, including the Collaborative Cross panel, the BxD recombinant inbred panel and a series of targeted single-gene knockouts. Bacterial variation was concurrently generated using whole-genome knockout libraries and panels of diverse *Mtb* clinical isolates, each of which contained a molecular barcode to allow parallel assessment of multiple *Mtb* variants in each of the diverse host backgrounds.

The disease spectrum of CC and BXD mice infected with *Mtb* libraries exceeded that seen in parental strains and standard inbred lines. Metrics of disease that are tightly linked in the standard C57BL/6J resistant model such as bacterial burden, dissemination, weight loss and inflammation were genetically separable in the diverse strains. We identified individual polymorphic host genome regions (QTLs) underlying lung and spleen bacterial load and host control of infection independently in the CC and BXD panels.

We additionally separated the clinical disease traits into intermediate phenotypes by determining the relative fitness of thousands of

bacterial mutants in the mouse panels. QTLs underlying differential bacterial fitness modules were identified, many of which mapped to the same host region as the clinical disease metrics. In addition to these overlapping "master loci", we identified further QTLs impacting the requirement of various bacterial genes, including virulence factors, nutrient acquisition and oxidative radical generation.

Overall, the strategy of using bacterial fitness profiles as reporters of the underlying host microenvironment is a sensitive and specific method for identifying disease-modifying host polymorphisms, demonstrating the power of a dual-genome systems genetics approach to understand the fundamental drivers of susceptibility to infection.

M304 Rosa Beddington Lecture: Single cells get together: cell lineage specification & tissue morphogenesis in the early mouse embryo. *AK. Hadjantonakis*. Memorial Sloan Kettering Cancer Center, New York, NY.

The last twenty years have seen major advances in our understanding of animal development. Genes regulating particular processes have been identified and, in many instances, they have been linked to human diseases, but how genetic information is transformed into three-dimensional tissues and organs remains an open question. We are seeking to fill this critical gap in knowledge by exploiting mouse genetics, high resolution quantitative imaging and gene expression profiling to investigate mechanisms of cell lineage specification, tissue patterning and morphogenesis, using the mouse as a model system. I will provide an overview of our interests and discuss some of our studies. My talk will reflect our focus on two distinct but interrelated events; blastocyst development and gastrulation.

M305 *Snai1* is required for stem cell maintenance in the mouse intestinal epithelium. *Helen Abud*[1*], Katja Horvay[1], Thierry Jarde[1], Franca Casagranda[2], Katharina Haigh[3,6], Christian Nefzger[4], Reyhan Akhtar[1], Thomas Gridley[5], Geert Berx[6,7], Jody Haigh[3,6], Jose Polo[4], Gary Hime[2]. 1) Cancer Program, Monash Biomedicine Discovery Institute, Clayton, Victoria, Australia; 2) Department of Anatomy and Neuroscience, University of Melbourne, Parkville, Australia,; 3) Australian Centre for Blood Diseases, Monash University, Clayton, Australia; 4) Australian Regenerative Medicine Institute, Monash University, Clayton, Australia; 5) Center for Molecular Medicine, Maine Medical Center Research Institute, Scarborough, Maine, USA; 6) Molecular and Cellular Oncology, Inflammation Research Center, VIB, Ghent, Belgium; 7) Department of Biomedical Molecular Biology, Ghent University, Ghent, Belgium.

The Snail family of transcription factors are well known for mediating epithelial to mesenchymal transitions and cell motility during both embryonic development and tumour invasion. Although they are generally regarded as markers of mesenchymal cells, Snail proteins have recently been implicated in regulating stem cell populations in several organs. *Snai1* is normally expressed in the intestinal epithelium within the crypt base columnar (CBC) stem cells and transit amplifying cell populations. Our studies have shown that both the expression and cellular localisation of *Snai1* is dependent on canonical Wnt signalling, a key regulatory pathway of intestinal stem cells. *Snai1* is up-regulated in polyps from *Apc*$^{min/+}$ mice indicating that *Snai1* may also play a part in the early stages of tumorigenesis in addition to promoting invasion of intestinal tumours. We investigated *Snai1* function in the mouse intestinal epithelium using an inducible conditional knockout approach and found that *Snai1* is required for maintenance of CBC stem cells and the appropriate balance of differentiated cell types. Further analysis of the effects of *Snai1* loss on the CBC stem cell population using a combination of Fluorescent Activated Cell Sorting (FACS), lineage tracing and *in vitro* organoid culture showed that loss of *Snai1* results in a decrease in cell proliferation and apoptotic loss of stem cells. In contrast, ectopic expression of *Snai1* using a conditional transgenic approach results in an increase in cell proliferation at the crypt base which correlates with elevated levels of expression of CBC stem cell markers. In addition, a decrease in secretory Paneth and enteroendocrine cells is observed. Our functional studies show that intestinal epithelium where *Snai1* is depleted fails to produce a proliferative response following radiation induced damage. These studies demonstrate a critical role for *Snai1* in survival of CBC cells and regeneration of the epithelial cell layer following damage. In conclusion, this suggests that *Snai1* has a key role in stem cell maintenance and control of lineage choice during cellular differentiation in the intestinal epithelium.

M306 Muscle fiber signaling scales the myogenic stem cell pool. *Christoph Lepper Lepper*[1], Sheryl Southard[1], Ju-Ryoung Kim[2], Richard Tsika[2]. 1) Carnegie Institution for Science, Baltimore, MD; 2) University of Missouri, Columbia, MO.

When unperturbed, quiescent somatic stem cells are poised to affect immediate tissue restoration upon trauma. Yet, little is known regarding the mechanistic basis controlling initial and homeostatic 'scaling' of adult stem cell pool sizes relative to their target tissues for effective regeneration. Here, we show that transgenic TEAD1 (TgTg(Ckm-Tead1)#Tsik)-expressing skeletal muscle features a dramatic hyperplasia of muscle stem cells (i.e. the satellite cells, SCs) but surprisingly without affecting muscle tissue size. Such super-numeral SCs attain a 'normal' quiescent state, accelerate regeneration, and maintain regenerative capacity over several injury-induced regeneration bouts. In dystrophic muscle, the TEAD1 transgene also ameliorated the pathology. We further demonstrate that hyperplastic SCs accumulate non-cell-autonomously via signal(s) from the TEAD1- expressing myofiber, suggesting that myofiber-specific TEAD1 overexpression activates a physiological signaling pathway(s) that determine initial and homeostatic SC pool size. We propose that TEAD1 and its downstream effectors are medically relevant targets for enhancing muscle regeneration.

M307 Plasticity, self-renewal and transcriptional dynamics – How embryonic stem cells stall for time in the decision making process? *J. M. Brickman*[1], William Hamilton[1], Yaron Mosesson[2], Naama Barkai[2], Chiara Francavilla[1], Jesper Olsen[1], Rob Illingworth[3], Jurriaan Hölzenspies[1], Wendy Bickmore[3]. 1) University of Copenhagen, Copenhagen, DK; 2) Weizmann institute of Science, Rehovot, Israel; 3) University of Edinburgh, Edinburgh, UK.

Embryonic stem cells (ESCs) are immortal cell lines derived from the peri-implantation mammalian embryo. Both ESCs and the embryos from which they are derived are remarkable, in that individual cells retrain the capacity to begin developmental anew, despite having **undergone a**

degree of patterning or differentiation. What is the basis for this plasticity at a transcriptional level? We have identified two new mechanisms regulating this process. The first involves a protective activity of Polycomb co-repressor complexes, that enables transcriptional stimulation in the absence of commitment. The second relies on the reversible disengagement of RNA Polymerase II from specific promoters in response to signaling. I will discuss these mechanisms and how they impact on the capacity of ESCs to retain their plasticity while they prime for differentiation but continue in self-renewal.

M308 Comparative Mendelian genomics and disease modeling in mice. *L. Reinholdt*[1], H. Fairfield[3], A. Srivastava[1], G. Ananda[2], R. Liu[2], A. Lakshminarayana[2], B. Harris[1], S. Y. Karst[1], L. Dionne[1], C. Kane[1], M. Berry[1], C. Byers[1], A. Czechanski[1], W. Martin[1], D. Berstrom[1]. 1) The Jackson Laboratory, Bar Harbor, ME; 2) The Jackson Laboratory for Genomic Medicine, Farmington, CT; 3) Maine Medical Research Institute.

Large consanguineous pedigrees, controlled environments, and genetically defined inbred strain backgrounds afforded by the laboratory mouse provide significant advantages for the discovery of Mendelian disease genes. The mouse as a disease model also offers the advantages of highly orthologous protein coding genes and mammalian physiology. Until the advent of high throughput sequencing, the rate of Mendelian disease gene discovery in both the human and mouse genomes was comparatively slow. Taking advantage of the world's largest collection of mouse strains with naturally occurring Mendelian disease phenotypes, we are using whole exome sequencing (WES) to discover naturally occurring disease mutations at unprecedented rates. To date, we have found over 90 new disease causing alleles. Over 80% of these alleles are in genes that have been implicated with Mendelian disease in the human population and an additional 10% are in genes that are novel, and, until recently, had yet to be associated with a mouse phenotype or human disease. These data demonstrate that even after nearly 100 years of research, spontaneously arising Mendelian mutations in the mouse genome continue to yield new discoveries. Despite our unprecedented rate of spontaneous mutation discovery, 50% of our cases remain unsolved using a standard exome sequencing analytics pipeline. Using a combination of approaches, we have found evidence that a large fraction of unsolved exome cases likely involve structural mutations that span exons but escape detection by standard exome pipelines. This result directly informs efforts to investigate the similar proportion of apparently Mendelian human phenotypes that are recalcitrant to exome sequencing. To advance our Mendelian disease modeling efforts we are integrating our disease allele discovery with parallel human Mendelian disease efforts by the Baylor-Hopkins Center for Mendelian Genomics (BHCMG). This integrated approach not only informs unsolved human exome cases, it also provides clinical information that we are using to implement disease relevant phenotyping and in some cases, the development of precise models through gene editing. We will provide several examples of new disease gene associations and mouse models including Diamond Blackfan anemia, Charcot-Marie-Tooth disease, Maffucci syndrome and idiopathic learning disability.

M309 A New Mouse Model for Costello Syndrome. *T. Sorg*[1], M.-C. Birling[1], G. Bou About[1], M.-F. Champy[1], H. Jacobs[1], H. Meziane[1], G. Pavlovic[1], A. Ayadi[1], Y. Herault[1], R. Rossignol[2], D. Lacombe[2]. 1) PHENOMIN - ICS, Illkirch, FR; 2) MRGM, Bordeaux, FR.

Costello Syndrome (CS) is a distinctive rare multisystem disorder comprising characteristic prenatally increased growth retardation, coarse facial features, redundant skin with deep palmar, plantar creases and papillomata of later onset. CS patients present also laxity of small joints, tight Achilles tendons, cardiac malformations, and developmental delay. The primary cause of CS was associated to the germ line activation of *HRAS* oncogene, with a common missense mutation G12S in 80% of the patients. Here we describe the generation and the consequent phenotypic characterization of a genetically engineered mouse model of CS, by introducing the oncogenic G12S mutation by homologous recombination into the mouse *Hras* gene, *Hras*$^{tm1.1Ics}$. The effect of the HRAS G12S mutation was evaluated on behavioral, visual, metabolic, cardiac and histological traits in young adult animals. The behavioral analysis revealed that HRAS^{G12S} mutant males displayed reduced locomotor activity, accompanied by decreased muscle strength and altered motor coordination performance. In addition, the cardiac exploration revealed that HRAS^{G12S} mutants exhibit a hypertensive phenotype combined with tachycardia. In conclusion, the HRAS^{G12S} mutant mice showed a polysyndromic phenotype reproducing some of the CS features observed in patients. The future study of the here-described CS mouse model should have a significant impact of our understanding of CS disease. The use of HRAS^{G12S} mutant mice as a CS mouse model opens up new fields of investigation to better understand the pathophysiology of the disease and to evaluate drugs dedicated to the reduction of the disease associated symptoms.

M310 A genetic epistasis analysis of an ENU-induced *Reln* mutant reveals that the C-terminal domain of RELN is required for binding to the receptor VLDLR but not to LRP8 (APOER2). *D. R. Beier*[1,2], S. Ha[1]. 1) Seattle Children's Research Institute, Seattle, WA; 2) University of Washington, Seattle, WA.

We have previously described a forward genetic screen for brain lamination defects using ENU-mutagenesis of a reporter line that marked specific layers of the cerebral cortex (Ha et al., Cereb Cortex, 2015). In this study we identified a novel hypomorphic allele of *reelin*, named *Reln*^{CTRdel}, which carries a splice-site mutation that results in a truncation of the C-terminal region (CTR) domain of the RELN protein product. The mutant secretes RELN, distinguishing *Reln*^{CTRdel} from *Orleans reeler,* which has a larger C-terminal truncation that completely prevents RELN secretion and phenocopies *reeler*. In contrast, *Reln*^{CTRdel} displays remarkably distinct phenotypes from *reeler*. First, the size and foliation of the cerebellum is normal, and this mutant is not ataxic. Second, the mutant does not have the inversion of cortical layers; however, both superficial and deep layer neurons migrate beyond normal boundaries. Third, the dentate gyrus morphology of the hippocampus is severely disturbed; most of the infrapyramidal blade is absent, while the suprapyramidal blade is present and better laminated when compared with *reeler*. Genetic epistasis analysis showed that *Reln*^{CTRdel}/*Lpr8*^{tm1Her} (AKA *Apoer2*^{null}) double homozygotes have phenotypes akin to *reeler*, while *Reln*^{CTRdel}/*Vldlr*^{tm1Her} mice do not. Given that *Apoer2*^{null}/*Vldlr*^{tm1Her} double-knockout mice resemble *reeler* and single-knockout mice are hypomorphic, we infer that *Reln*^{CTRdel}/*Apoer2*^{null} double homozygotes have both receptor pathways disrupted. Therefore, the epistasis results

suggest that CTR-truncation disrupts an interaction with VLDLR, while the APOER2 signaling pathway remains active, which accounts for the hypomorphic phenotype in *Reln*^{CTRdel} mice. A receptor binding assay confirms that CTR-truncation of RELN significantly decreases binding to VLDLR, but not to APOER2. Taken together, the *in vitro* and *in vivo* results demonstrate that the absence of the CTR domain can limit receptor-binding specificity of RELN. Our discovery, using a focused neurodevelopmental analysis, of an allele of *reeler* that would likely not otherwise be identified (as it is not ataxic) illustrates the utility of unbiased forward genetic approaches in the mouse.

M311 Inhibition of activin A stops the regrowth of surgically resected heterotopic bone in a mouse model of Fibrodysplasia Ossificans Progressiva and indicates a new potential path to therapy. *A. N. Economides*[1,2*], L. Huang[1], L. Q. Xie[1], N. Das[1], X. Wen[1], L. Wang[1], A. J. Murphy[1], V. Idone[1], S. J. Hatsell[1]. 1) Regeneron Pharmaceuticals, Tarrytown, NY; 2) Regeneron Genetics Center, Tarrytown, NY.

Fibrodysplasia ossificans progressiva (FOP) is a rare genetic disorder characterized by episodic yet cumulative heterotopic ossification (HO), which develops connections to the normal skeleton, resulting in progressive immobility. The heterotopic bone cannot be resected because such procedures result in regrowth of the resected lesions and induction or exacerbation of additional HO. FOP is caused by mutations in ACVR1, with the most common mutation altering arginine 206 to histidine (ACVR1^{R206H}). Using a genetically accurate mouse model of FOP – 129;B6N-*Acvr1*^{tm2Vlcg} (aka *Acvr1*$^{[R206H]FlEx}$)/+ *Gt(ROSA26)Sor*$^{tm3.1(cre/ERT2)Vlcg}$/+ – we have demonstrated that unlike wild type ACVR1, ACVR1^{R206H} perceives activin A as an agonistic ligand, and that it is this new property of ACVR1^{R206H} that drives HO. Furthermore, using neutralizing anti-activin A antibodies we have shown that there is an absolute requirement for activin A to initiate HO (Hatsell, Idone et al; PMID 26333933). Here we extend our findings and demonstrate that inhibition of activin A in a delayed dosing setting (where the mice are allowed to form HO over three weeks and then dosing with the antibody is initiated), as well as in a surgery setting (where an HO lesion is resected while the mice are administered antibody) provides 'therapeutic' benefit. In both settings, inhibition of activin A stops further growth of existing or partially resected HO lesions. Importantly, whereas surgery (in the absence of anti-activin A) induces 'explosive' growth of the resected lesion as well as nearby lesions, this effect is greatly inhibited in the presence of the antibody. Given that the majority of FOP patients already present with ongoing or existing HO at the time of diagnosis (and also the number of patients with developed disease), our results not only demonstrate that activin A remains a key HO-promoting factor even after initiation of HO but also indicate a new potential path to therapy, and indeed one where surgical intervention may be incorporated.

M312 Driving discovery and characterisation of novel genes important for bone biology by combining high-throughput mouse phenotyping and a tissue-based deep phenotyping platform. *C. J. Lelliott*[1], J. Logan[2], S. Beck-Cormier[3], D. Lafont[1], A. Swiatkowska[1], H. Protheroe[2], S. Pearson[1], S. Maguire[1], A. Gogakos[2], N. Butterfield[2], V. Leitch[2], J. K. White[1], L. Beck[3], G. R. Williams[2], J. H. Bassett[2], Sanger Mouse Pipelines. 1) Wellcome Trust Sanger Institute, Hinxton, Cambridge, UK; 2) Molecular Endocrinology Group, Department of Medicine, Imperial College London, London, UK; 3) Institut National de la Sante et de la recherche Medicale, U791, LIOAD, Nantes, France.

Bone diseases causing abnormal development or maintenance of structure and function are an area of intense scientific investigation. Bone mineralization measurements by dual-energy X-ray absorptiometry (DEXA) are performed by many International Mouse Phenotyping Consortium members and could identify new candidate genes for focussed study. Data from 717 alleles from Sanger Mouse Pipelines (C57BL/6N, LabDiet #5021), was analysed by a Mixed-Model approach. 58 lines (8%) had hits for one or more bone mineral measurement: bone mineral density (BMD – 42 hits), volumetric BMD (vBMD – 19 hits) and bone mineral content accounting for body weight (BMC+BW – 37 hits). Hits were distributed: 1 hit – 26 alleles, 2 hits – 26, 3 hits – 6. Using the power of the Origins of Bone and Cartilage Disease platform (http://www.boneandcartilage.com), we further characterised two lines that displayed reduced bone parameters. Mice lacking the phosphate transporter *Slc20a2* have reduced BMD and BMC+BW (BMC+BW effect size: Females -9.77%; Males -9.38%) in DEXA. Using microcomputed tomography and histology, we found that femurs from *Slc20a2*$^{tm1a(EUCOMM)Wtsi}$-/- mice show impaired linear growth, particularly at younger ages. *Slc20a2*-/- femurs display delayed ossification linked to reduced growth plate width, as well as reduced trabecular bone content and reduced mineralization in both trabecular and cortical bone. Consequently, the mechanical properties of *Slc20a2*-/- femurs were altered in a three-point bend test, resulting in weak, brittle but flexible bones. Similarly, mice lacking *Tram2*, a component of the translocon, had significantly reduced BMD, vBMD and BMC+BW (BMC+BW effect size: Females -18.67%; Males -17.93%) in DEXA. Femurs from *Tram2*$^{tm1a(KOMP)Wtsi}$-/- mice were short, with thinner cortical bone, less trabecular bone and were weak yet flexible in the three-point bend test. As well as long-bone phenotypes, both *Slc20a2*-/- and *Tram2*-/- mice had abnormal skull and craniofacial morphologies. In *Tram2*-/- mice, this, combined with disrupted ossicle shape, correlates with a substantially raised hearing threshold without indication of auditory sensorineural impairment. Overall, this data shows the additive value of combining high-throughput phenotyping with specialist platforms to enhance the knowledge generated for specific areas of high medical need.

M313 From mouse to human and back to mouse: sodium channel mutations and epilepsy. *Miriam Meisler*, Rosie Bunton-Stasyshyn, Julie Jones, Jacy Wagnon. Univ Michigan, Ann Arbor, MI.

A transgene insertional mutation in the early 1990s led to the discovery of the mouse *Scn8a* gene, which encodes one of the most abundant sodium channels involved in generation of action potentials in mammalian neurons. A series of loss-of-function and gain-of-function alleles in the mouse revealed many of the *in vivo* roles of SCN8A and other gene family members. In 2012, a *de novo* mutation of *SCN8A* was identified in a child with Epileptic Encephalopathy, a severe disorder that includes seizure onset in the first year of life, developmental delay and intellectual disability. Overall, *de novo* sodium channel mutations account for 5% of cases, and more than 150 indivduals with *SCN8A* mutations have been identified. Functional studies in transfected cells demonstrate that 8/10 mutations cause incomplete channel inactivation or premature activition, both leading to neuronal hyperexcitability. A knock-in mouse model carrying one human mutation is being used to

characterize the functional impact on various classes of neurons and in the heart, as well as responses to standard epileptic drugs and novel compounds. The interplay of human and mouse genetics has been essential to our understanding of the role of sodium channel gene mutations in neurological disorders.

M314 Cas9 RNA-guided nuclease gene editing – rapid disease modeling in mice. *L. M. J. Nutter*[1,2], J. Ellegood[3], M. Gertsenstein[2], A. Flenniken[2,4], R. M. Henkelman[1], C. McKerlie[1,2], J. P. Lerch[1], J. Rossant[1]. 1) The Hospital for Sick Children, Toronto, ON, CA; 2) The Centre for Phenogenomics (TCP), Toronto, ON, CA; 3) Mouse Imaging Centre, Toronto, ON, CA; 4) 4Lunenfeld-Tanenbaum Research Institute, Toronto, ON, CA.

Cas9 RNA-guided nuclease (CRISPR/Cas9) gene editing is revolutionizing genetic modification in many species. The Model Production Core at The Centre for Phenogenomics (TCP) is a national facility serving academia and industry in Canada and internationally. TCP has implemented CRISPR/Cas9 editing in mice to produce knockout mutations for the International Mouse Phenotyping Consortium as well as knockout and point mutant alleles for investigators seeking to model specific human diseases.

We produced models by co-injecting mouse zygotes with target-specific guide RNA(s), Cas9 endonuclease, and when required, a homologous repair template. We have designed and produced multiple lines with disease-associated point mutations for mechanistic and pre-clinical studies as well as knockout mouse lines for both medium- and high-throughput phenotype screens. Our success rate for requested alleles is >80% at >50 different loci in the C57BL/ 6NCrl background. No off-target mutagenesis was detected for 12 different gRNAs in 93 N1 mice for 852 potential off-target loci. However, real-time quantitative PCR for repair template copy number has identified multi-copy insertions in some mice. Thus, while off-target mutagenesis appears to be a very low risk with locus-specific guide RNAs, quality control should include copy number screens for repair templates when they are used.

We set out to compare phenotypes of ES cell-derived and Cas9-derived mutant lines; assess novel mutants for neuroanatomical phenotypes; and produce mouse models of human disease. We produced two *Tox3* knockout mouse lines; one from targeted ES cells and the other using Cas9, C6N-*Tox3*$^{<tm1b(KOMP)Mbp}$*/MbpCrl* and C6N-*Tox3*^{em1Tcp}, respectively. For phenotyping, we intercrossed heterozygotes within each line. Homozygotes for each of these alleles both died before 4 weeks of age and had reduced brain volume. We also used Cas9 to produce several knockout mouse lines in genes associated with Autism Spectrum Disorder as part of a medium-throughput screen to identify neuroanatomical phenotypes. We show that many of these mutants had both *in vivo* behavioural phenotypes as well as brain dysmorphology compared to wild type. Finally, we have produced and delivered several disease-associated point mutants that are currently under study. One of these presents with seizures, a clinical sign observed in the patient population. This mutant is now being used to assess hyperexcitability in cortical neurons as well as in a drug screen.

In conclusion, Cas9 mutagenesis is an efficient way to produce mutant mouse lines at high throughput with specific gene mutations for modeling human disease.

POPULATION, EVOLUTIONARY, AND QUANTITATIVE GENETICS MEETING

Plenary and Platform Session Abstracts

Population, Evolutionary, And Quantitative Genetics Meeting

SCHEDULE AT-A-GLANCE

Wednesday, July 13		
2:00pm-9:30pm	Speaker Ready Room Open	Hall of Cities - Anaheim
7:00pm-9:00pm	Scientific Session: PEQG Keynote 1	Crystal Ballroom
9:00pm-11:00pm	Opening Mixer with Exhibits	Cypress Ballroom
Thursday, July 14		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities -Anaheim
7:45am-10:00am	Genetics and Determinants of Health Joint Plenary Session	Palms Ballroom
8:00am-4:00pm	Exhibits Open	Cypress Ballroom
9:00am-8:00pm	Demo Room: MOD (FlyBase, MGI, SGD, WormBase, Zfin) Demo Room Open	Palms Ballroom Canary 3-4
10:30am-12:30pm	Scientific Session: Natural Selection and Adaptation	Crystal Ballroom
12:30pm-1:30pm	Mentoring Roundtables #1	North Tower - Harbor Beach
12:30pm-1:30pm	Speaking Up for Genetics and Model Organism Research	Crystal Ballroom H
1:30pm-3:30pm	Poster Presentations 1:30pm-2:30pm: Even-numbered poster 2:30pm-3:30pm: Odd-numbered posters	Cypress Ballroom
1:30pm-3:30pm	GeneticsCareers Center and Job Fair	Cypress Ballroom 1C
4:00pm-6:00pm	Scientific Session: James F. Crow Symposium	Crystal Ballroom
4:00pm-6:00pm	Plenary Session and Workshop for Undergraduate Researchers	North Tower - Sawgrass
7:45pm-9:45pm	Scientific Session: PEQG Keynote 2	Crystal Ballroom
10:00pm-11:30pm	*Science Cafe Event	Palms Ballroom Sabal
Friday, July 15		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities - Anaheim
8:00am-9:30am	Scientific Session: Cryptic Variation and Robustness	Crystal Ballroom
8:00am-4:30pm	Exhibits Open	Cypress Ballroom
9:00am-8:00pm	Demo Room: MOD (FlyBase, MGI, SGD, WormBase, Zfin) Demo Room Open	Palms Ballroom Canary 3-4
10:00am-12:00pm	Scientific Session: Mutation & Recombination	Crystal Ballroom
12:00pm-1:30pm	*Editor's Panel Discussion and Roundtable	North Tower - Harbor Beach
1:30pm-3:30pm	Poster Presentations 1:30pm-2:10pm: "A" poster authors present 2:10pm-2:50pm: "B" poster authors present 2:50pm-3:30pm: "C" poster authors present	Cypress Ballroom
1:30pm-3:30pm	GeneticsCareers Center	Cypress Ballroom 1C
2:00pm-2:45pm	GeneticsCareers Workshop - Nailing the Job Talk	Cypress Ballroom 1B
4:00pm-6:00pm	Scientific Session: Molecular Evolution	Crystal Ballroom
6:00pm-7:30pm	*Women in Genetics Panel and Networking	North Tower - Harbor Beach
7:30pm-9:30pm	Development and Evolution Joint Plenary Session	Palms Ballroom

** Ticketed Event*

#TAGC16

Saturday, July 16		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities - Anaheim
8:00am-10:00am	Workshops: See topics and descriptions in the Workshop Section	Multiple locations
8:00am-12:00pm	Exhibits Open	Cypress Ballroom
8:00am-900am	Trainee Bootcamp Workshops: Session 1	North Tower
9:00am-10:00am	Trainee Bootcamp Workshops: Session 2	North Tower
10:00am-12:00pm	Poster Presentations 10:00am-11:00am Odd-numbered posters 11:00am-12:00pm Even-numbered posters	Cypress Ballroom *(Posters must be removed by 1pm)*
10:00am-12:00pm	GeneticsCareers Center	Cypress Ballroom 1C
10:30am-11:15am	GeneticsCareers Workshop	Cypress Ballroom 1B
12:15pm-1:45pm	*Mentoring Roundtables #2	North Tower - Harbor Beach
1:45pm-3:45pm	Scientific Session: Population Genetics	Crystal Ballroom
4:00pm-6:00pm	Scientific Session: Complex Trait Evolution	Crystal Ballroom
7:30pm-9:30pm	Scientific Session: PEQG Keynote 3	Crystal Ballroom
Sunday, July 17		
8:00am-10:00am	Scientific Session: Epistasis	Crystal Ballroom
10:30am-12:30pm	Technology and its Application Joint Plenary Session	Palms Ballroom

** Ticketed Event*

P315 Evolution of gene expression: from mutation to polymorphism to divergence. *Patricia J. Wittkopp*. Univ Michigan, Ann Arbor, MI.

Gene expression is controlled by a complex network of molecular interactions. Genetic changes that alter this network contribute to phenotypic differences within and between species. To better understand how mutation and selection affect the evolution of gene expression, we have investigated properties of new mutations that create regulatory variation in *Saccharomyces cerevisiae* and compared their effects to those of regulatory variants segregating in the wild. Comparisons between these two datasets are providing are being used to make inferences about how regulatory networks evolve. Genetic variation segregating within a species reflects the combined activities of mutation, selection, and genetic drift. In the absence of selection, polymorphisms are expected to be a random subset of new mutations; thus, comparing the effects of polymorphisms and new mutations provides a test for selection. When evidence of selection exists, such comparisons can identify properties of mutations that are most likely to persist in natural populations. We have been investigating how mutation and selection contribute to variation in cis- and trans-regulatory sequences controlling gene expression by empirically determining the effects of new mutations and polymorphisms in *Saccharomyces cerevisiae.*.

P316 The hidden complexity of Mendelian inheritance in natural populations. *J. Schacherer*[1], J. Hou[1], A. Sigwalt[1], D. Pflieger[1], J. Peter[1], T. Fournier[1], M. Dunham[2]. 1) University of Strasbourg, Strasbourg, FR; 2) University of Washington, Seattle, US.

More than a century after the rediscovery of Mendel's law, we still understand relatively little about the spectrum of the genetic complexity of traits. This lack of knowledge constitutes a gap in our basic understanding of how genotype determines phenotype. To obtain a comprehensive picture of the genetic complexity spectrum, we performed a species-wide survey of the inheritance patterns of a large number of traits using the *Saccharomyces cerevisiae* yeast model system. We performed systematic crosses between the laboratory strain (Σ1278b) and 41 diverse natural isolates covering a high genetic divergence. We quantitatively measured the fitness variation in the offspring for each cross across a large panel of stress conditions. By analyzing the distribution and the segregation of the more than 1,100 cross/trait combinations, we obtained the first estimation of the number of cases showing a Mendelian inheritance pattern within a natural population. Our results showed that 8.9% (98 out of 1,105 cases) are monogenic traits with Mendelian inheritance. Using mapping strategies combined with next-generation sequencing, we then precisely identified the genomic loci involved in the observed Mendelian traits. Interestingly, the identified Mendelian loci are not randomly distributed but rather genetically linked, leading to co-segregating phenotypes. In addition, we traced the phenotypic effect and genetic inheritance of one monogenic allele we characterized across multiple genetic backgrounds. Interestingly, increased genetic complexity was observed in 30% of the cases, with significant deviations from the Mendelian expectation. Our results clearly show that monogenic mutations might have different phenotypic outcomes with different inheritance patterns ranging from a Mendelian to a complex inheritance, including cases with intermediate levels of complexity. Overall, these data and analysis provide, for the first time, a comprehensive picture of natural genetic variants contributing to the onset of Mendelian traits, and illustrate the extent to which different genetic background could impact the inheritance pattern of these traits in a continuous way in terms of complexity. In fact, when taking into account the natural population diversity, the hidden complexity of traits could be substantial, perplexing the phenotypic predictability even for simple Mendelian traits.

P317 Parallel Gene Expression Differences between Low and High Latitude Populations of two *Drosophila* species. *Li Zhao*, David J. Begun. Department of Evolution and Ecology, UC Davis, Davis, CA.

Gene expression variation within species is relatively common, however, the role of natural selection in the maintenance of this variation is poorly understood. Here we study geographic differences in gene expression in recently established low and high latitude populations of two closely related species of *Drosophila, Drosophila melanogaster* and *D. simulans*, to determine whether the two species show similar patterns of population differentiation, consistent with a role for spatially varying selection in maintaining gene expression variation. We observed a significant excess of genes exhibiting differential expression in both species, consistent with parallel adaptation to heterogeneous environments. Moreover, the majority of genes showing parallel expression differentiation showed the same direction of differential expression in the two species and the magnitudes of expression differences between high and low latitude populations were correlated across species, further bolstering the conclusion that parallelism for expression phenotypes results from spatially varying selection. Comparison of inter-population sequence differentiation and expression differentiation suggests that cis-acting variants play a role in geographic expression differentiation.

P318 *Trans* regulatory architecture of genetic transcriptome variation from 1,000 yeast individuals. *Frank W. Albert*[1,2], Joshua S. Bloom[1], Jake Siegel[1], Laura Day[1], Leonid Kruglyak[1,3]. 1) University of California, Los Angeles, CA; 2) University of Minnesota, Minneapolis, MN; 3) Howard Hughes Medical Institute, Los Angeles, CA.

* FWA and JSB contributed equally

Regulatory variation is an important source of genetic variation for many traits and can be identified as "expression quantitative trait loci" (eQTL). To date, all eQTL studies have been hampered by low statistical power due to limited sample sizes. As a consequence, the full extent and nature of regulatory variation remains unknown.

We have addressed this limitation in the yeast *Saccharomyces cerevisiae*. We used mRNA sequencing to profile gene expression in more than 1,000 recombinant individuals generated from a cross between two yeast isolates. The statistical power of this dataset is high enough to map thousands of previously "missing" eQTL that together account for ~80% of the heritability of gene expression. Thus, our data provide a nearly exhaustive view of how genetic variation influences the transcriptome.

We identified 34,318 eQTL for 6,210 transcripts. A typical transcript is influenced by a median of 6 and up to 20 eQTL, several fold more than

previously seen. While 43% of all genes had a local eQTL that is located close to the gene, most eQTL are located elsewhere in the genome and influence gene expression in *trans*. The aggregate effect of the *trans* eQTL was larger than that of the local eQTL, illustrating the importance of *trans* acting variation.

Rather than appearing randomly across the genome, the newly discovered *trans* eQTL were highly structured, such that the vast majority fell into one of 111 hotspot regions that each affect the expression of many genes. Some of these hotspots have extraordinarily wide-reaching effects and influence thousands of transcripts across all cellular processes, while others specifically influence certain pathways. By combining information from all genes that map to a given hotspot, we can fine-map the causal hotspot location with high precision, in 26 cases to single-gene resolution of less than 1.5 kb. This permits – for the first time – a systematic and unbiased analysis of the types of genes that act as *trans* eQTL. *Trans*-acting variation generates structure in the yeast transcriptome such that groups of genes are affected by multiple eQTL in a combinatorial fashion. Finally, despite our high statistical power, many local eQTL did not act as *trans* eQTL for other genes. This might indicate that the expression changes these eQTL cause at their local genes do not further affect cellular physiology, at least not in ways that are reflected in the transcriptome. This raises important questions about the characteristics of genes where local regulatory variation does have cellular and phenotypic consequences.

P319 The genomic basis of environmental adaptation in house mice. *M. Phifer-Rixey*[1], K. Bi[1], K. G. Ferris[1], M. J. Sheehan[2], D. Lin[1], S. M. Keeble[3], J. M. Good[3], M. W. Nachman[1]. 1) UC Berkeley, Berkeley, CA; 2) Cornell University, Ithaca, NY; 3) University of Montana, Missoula, Missoula, MT.

Understanding the genetic basis of adaptation is a fundamental goal of evolutionary biology. Many of the first examples connecting adaptive phenotypes to specific genetic variants implicated single loci of large effect (e.g., *Mc1r* in rock pocket mice, *Eda* in sticklebacks, FRIGIDA in *Arabidopsis thaliana*). Nevertheless, the majority of adaptive phenotypes are likely to be complex and contingent on interactions between many genes and the environment. Progress in identifying the genetic basis of complex traits has been more limited. The incredibly successful colonization of the Americas by house mice offers a unique opportunity to study environmental adaptation, complex traits, and population genetics in an invasive species that is also the premier mammalian medical model for humans. Despite arriving in the Americas relatively recently with European settlers, the house mouse (*Mus musculus domesticus*) has expanded into a wide variety of climates and habitats. We sampled five populations of house mice in eastern North America distributed along a latitudinal gradient and established laboratory colonies of mice from the ends of this transect. Using genome and exome scans, gene expression studies, and phenotypic analyses in the field and in the lab, we found strong evidence of environmental adaptation. We identified several phenotypes tied to fitness that differ among the most extreme populations, and those differences persist in the lab over several generations indicating that they have a genetic basis. We also identified specific genes as candidates for environmental adaptation. Importantly, most candidate SNPs are non-coding or synonymous, indicating that regulatory evolution has been key to the success of house mice in varied climates.

P320 Parallel selective sweeps of selfish *Segregation Distorter* complexes in African and European *Drosophila melanogaster* populations. *A. M. Larracuente*, C. Brand, D. C. Presgraves. University of Rochester, Rochester, NY.

Segregation distorters are selfish genetic elements that unfairly achieve biased transmission through the germline. Found across a wide variety of taxa including fungi, plants, insects and mammals, segregation distorters can rapidly increase in frequency in natural populations and trigger the evolution of suppressors across the genome. One of the best-studied male segregation distorters is the autosomal *Segregation Distorter* (*SD*) gene complex of *Drosophila melanogaster*. Males heterozygous for *SD* and a wild type chromosome transmit *SD* to over >95% of their progeny, whereas heterozygous females transmit *SD* fairly to 50% of their progeny. *SD* is found at frequencies of ~1-5% in natural populations across the globe. Cosmopolitan *SD* chromosomes involve a main driving locus on chromosome *2L—Sd-RanGAP—*and several upward enhancers that strengthen drive on both *2L* and *2R*. *SD* chromosomes often tighten linkage among enhancers and *Sd-RanGAP* via the recruitment of chromosomal inversions that suppress recombination. Suppressed recombination prevents the distorter from recombining onto a sensitive target background and generating self-distorting “suicide” genotypes. African and European *SD* chromosomes appear molecularly different—they do not share inversions and we find that suppressors of European *SD* chromosomes do not suppress African *SD* chromosomes. While inversions provide short-term benefits to *SD*, the reduced recombination entails long-term costs due to the associated reduced efficacy of natural selection. To study the consequences of suppressed recombination, we performed whole-chromosome population genomics analyses of *SD* chromosomes sampled from African and European populations. We Illumina-sequenced 10 haploid embryos from Zambia and 10 adults from France. We find a dearth of nucleotide variation on French *SD* chromosomes that begins at *Sd-RanGAP* on chromosome *2L*, spans the centromere and extends 4 Mb into chromosome *2R*. In contrast, we find a more dramatic dearth of nucleotide variation on Zambian *SD* chromosomes that begins at *Sd-RanGAP* on chromosome *2L,* spans the centromere and extends for ~22.5 Mb across chromosome *2R*— a massive sweep signal that suggests very recent and strong selection. We therefore detect a signature of parallel sweeps of independent multi-locus selfish *SD* complexes in Africa and France. Taken together, differences in (*i*) the structure of the selective sweeps, (*ii*) the chromosomal inversions involved, and (*iii*) responses to genetic suppressors of *SD*, imply that Zambian and French *SD* gene complexes have functionally diverged from one another.

P321 Diverse genetic architectures lead to the same cryptic phenotype in a yeast cross. *Ian Ehrenreich*, Matthew Taylor, Joann Phan, Jonathan Lee, Madelyn McCadden. University of Southern California, Los Angeles, CA.

Cryptic genetic variants that do not typically influence traits can interact epistatically with each other and mutations to cause unexpected phenotypes. To improve understanding of the genetic architectures and molecular mechanisms that underlie these interactions, we

comprehensively dissected the genetic bases of 17 independent instances of the same cryptic colony phenotype in a yeast cross. In eight cases, the phenotype resulted from an interaction between a spontaneous mutation and one or more cryptic variants. The total number and specific identities of the detected cryptic variants depended on which gene was mutated. In the nine remaining cases, the phenotype arose without a mutation due to higher-order interactions only involving cryptic variants. These mutation-independent cases fell into two classes, which could be distinguished by the occurrence of recombination within a specific ~1.3 kb genomic interval in the promoter of a required cell surface protein. Our results may be relevant to other species and disease, as most of the mutations and cryptic variants identified in our study reside in components of the evolutionarily conserved and oncogenic Ras signaling pathway.

P322 Genome-wide selection component analysis in a wild pedigreed population of the Florida Scrub-Jay. *Andrew G. Clark*[1], Elissa Cosgrove[1], Huijie Feng[1], Ishaan Jhaveri[1], Ashish Akshat[1], Reed Bowman[2], John W. Fitzpatrick[3], Nancy Chen[3,4]. 1) Cornell Univ, Ithaca, NY; 2) Archbold Biological Station, Venus, FL; 3) Cornell Lab of Ornithology, Ithaca, NY; 4) University of California, Davis, CA.

Analysis of contemporary evolution is the only way to directly test many fundamental questions in evolutionary biology, but we usually lack the combined phenotypic and genomic data over time in natural populations required for such studies. In addition, most current approaches for inferring natural selection do not have the opportunity to incorporate the additional power gained from access to a full pedigree. Here, we study short-term selection using a 25-year genomic, phenotypic, and pedigree dataset in the Florida Scrub-Jay (*Aphelocoma coerulescens*), an iconic species on the U. S. Endangered Species List that has drastically decreased in number during the past half-century. A population of Florida Scrub-Jays at Archbold Biological Station has been studied intensively since 1969, providing a 12-generation pedigree among the most accurate and extensive for any wild vertebrate species. For all locally recruited birds in the population, we have full records of individual lifespans, annual fecundity, and lifetime fitness; similar records exist for immigrant breeders except for exact lifespan. We sequenced and assembled the Florida Scrub-Jay genome and used custom Illumina Beadchips to genotype every individual in our study population over the past two decades (3,838 individuals total) at 15,416 genome-wide SNPs. We used gene dropping to explicitly sample gametes in each generation on the known pedigree and asked whether the observed allele frequency dynamics of each SNP were consistent with a pure drift process. Numerous SNPs departed significantly from the null model and showed frequency dynamics consistent with perturbation by selection. We then tested for selection acting on specific life-cycle stages by tailoring hierarchical selection component analysis to take full advantage of exhaustive population sampling. We identified a number of loci that clearly exhibited male gametic selection, sexual selection, and viability selection. By combining sensitive pedigree-based inferences of net selection with fine-scale dissection of selection components, this study provides a detailed assessment of the role of selection in perturbing allele frequency dynamics in a rapidly declining population. Results suggest a role of selection in maintaining variation even in the face of population decline, and may help guide conservation efforts.

P323 *Drosophila melanogaster*-specific genes rapidly evolved strong fitness effects. *Nicholas VanKuren*, Manyuan Long. University of Chicago, Chicago, IL.

Genome regions that are highly conserved between distantly-related organisms are assumed to have important fitness effects that have been preserved by natural selection over long periods of time. This assumption has led to two others: 1) the evolution of important genome regions is slow and 2) new genome regions do not have significant fitness effects. However, new genetic variants are precisely those that cause individuals to vary and thus drive evolution. A complete understanding of how and how rapidly genomes and fitnesses change thus depends on characterization of the evolutionary forces that act on and the fitness effects of new variants.

We investigated these characteristics of a set of 27 *Drosophila melanogaster*-specific genes. These genes were formed by duplication and fixed after *D. melanogaster* and *D. simulans* diverged (~2 mya). We screened 12 *D. melanogaster*-specific genes for severe fitness and morphological defects using available mutants and RNA interference (RNAi). Specific and constitutive expression knockdown of 4/12 genes is lethal. That is, significantly fewer (1 gene) or no (3 genes) RNAi flies survive to adulthood. Thus, 1/3 genes rapidly acquired a critical fitness effect. Natural selection appears to have dominated this process, as 50% of *D. melanogaster*-specific genes reside in regions with extremely negative Tajima's *D* and/or Fay and Wu's *H* statistics. These findings suggest that *D. melanogaster*-specific genes were subject to recent and strong selection, and are supported by comparisons of polymorphism and divergence in the surrounding regions. While *D. melanogaster*-specific genes exhibit few signatures of rapid sequence evolution, 37% have accumulated insertion/deletions, recruited additional amino acids, or are chimeric relative to their parent copies. In addition, duplicate pairs rapidly diverged in expression patterns across tissues and developmental times.

We thus provide direct and indirect evidence that *D. melanogaster*-specific genes can rapidly evolve significant fitness effects. Our results support a model in which 1) new genes become distinct from their parents concurrent with their formation, 2) selection immediately acts on new genes to drive them to fixation or purge them from the population, and 3) new gene function and fitness effects are refined during and after fixation. These findings suggest that new genes can play important roles in determining organismal fitness shortly after they are formed and that importance does not require long-term conservation.

P324 Examining the effects of natural selection on linked neutral divergence. *T. N. Phung*, C. D. Huber, K. E. Lohmueller. University of California, Los Angeles, Los Angeles, CA.

A major goal in evolutionary biology is to understand the processes that shape patterns of genetic variation across genomes. One process that has received a lot of attention is natural selection. In particular, numerous studies in a variety of species have shown that neutral genetic diversity (intra-species differences) has been reduced at sites linked to those under selection. However, the effect of selection on neutral sequence divergence (inter-species differences) remains ambiguous. While some empirical studies have reported correlations between

divergence and recombination which is interpreted as empirical evidence for natural selection reducing neutral linked divergence, theoretical arguments argued otherwise, especially for species that have diverged long ago. Here we address these outstanding issues by examining how natural selection has affected divergence between both closely and distantly related species. We show that neutral divergence is negatively correlated with functional content and positively correlated with estimates of background selection from primates, which is a measure of how negative selection affects linked neutral sites. These patterns persist even when comparing humans and mice, species that split 75 million years ago. Coalescent models indicate that background selection can generate these patterns, suggesting that natural selection has affected linked divergence between distantly related species. Our theoretical and simulation results show that even when the contribution of ancestral polymorphism to divergence is small, background selection in the ancestral population can still explain a large proportion of the variance in divergence across the genome. Thus, the view that selection does not affect divergence at linked neutral sites needs to be reconsidered. These findings also suggest that the effects of natural selection affecting linked neutral sites cannot be ignored when studying neutral divergence. Our work has important implications for understanding evolution of genomes and interpreting patterns of genetic variation.

P325 Genome-wide signals of adaptation in mammals and the arms race with viruses. *D. Enard*[1], Arya Iranmehr[2], Dmitri Petrov[1]. 1) Stanford University, Stanford, CA; 2) UCSD, San Diego, CA.

In “The Causes of Evolution” published in 1932, Haldane formulated the hypothesis that pathogens are a major driver of hosts' evolution. Adaptation against pathogens has since then been studied mostly in genes specialized in the immune response.

Yet pathogens, and in particular viruses, interact with hundreds to thousands of host proteins that are not specialized in the immune response. Whether adaptation to viruses has typically involved only specialized immune, antiviral proteins or has affected a broad array of proteins is unknown. Here, we analyze patterns of adaptation in thousands of virus-interacting proteins at different evolutionary time scales ranging from the whole mammalian phylogenetic tree to the past 10,000 years of human evolution.

Over long evolutionary time scales, we find that virus-interacting proteins have experienced strongly increased rates of adaptation across the entire mammalian phylogeny, from primates to rodents to bats and elephants. In the human branch, we estimate that 30% of all adaptive protein changes since divergence with chimpanzees were driven by viruses.

During recent human evolution, we find that virus-interacting proteins exhibit a very strong excess of partial and complete sweeps. Importantly, recent human adaptation against viruses is driven not only by immune proteins but instead by proteins from a wide range of host cellular functions.

Our results show that the influence of pathogens extends well beyond the classic cases of specialized immune proteins, and that pathogens are a major driver of adaptation at the whole genome level.

P326 Evolution of gene expression in giant island mice. *Mark Nolte*[1,2], Colin Dewey[3], Bret Payseur[1]. 1) Laboratory of Genetics, University of Wisconsin, Madison, WI; 2) Supported by NHGRI training grant to the Genomic Sciences Training Program 5T32HG002760, Madison, WI; 3) The Department of Biostatistics and Medical Informatics, University of Wisconsin, Madison, WI.

Island colonizing organisms often evolve extreme body sizes. Notable examples of this phenomenon include evolved dwarfism in an extinct insular elephant and hominin, and acquired gigantism in numerous insular rodents. Although the generality of the phenomenon suggests common evolutionary mechanisms, the genetic basis of extreme body size evolution on islands remains poorly understood. A striking case of island gigantism is that observed on Gough Island (GI) where house mice evolved to become the largest wild representatives of their species in just 200 years. To illuminate the genetic basis of metabolic processes contributing to the extreme size of GI mice and to nominate candidate genes involved in gigantism evolution we characterized gene expression evolution in three metabolic organs. A total of 100 RNA-sequencing libraries were constructed for GI mice and a wild-derived strain with size representative of mainland mice (WSB) for five conditions: the liver from embryonic, 2-week, and 4-week old mice, and the gonadal adipose depot and hypothalamus from 4-week old mice. We employed the software package RSEM to align reads and quantify transcripts. Using the R package DESeq2, we detected differential expression between GI and WSB mice at thousands of genes in each condition. The embryonic liver and adipose manifested the most differentially expressed (DE) genes. The adipose exhibited a significant excess of highly expressed genes in large magnitude fold change classes, indicating elevated activity of the pathways constructed by these genes (including metabolically driven cell growth). Monitoring patterns of liver-specific gene expression across three time points enabled grouping of genes with similar temporal expression profiles, shedding light on the evolution of co-regulated genes acting to promote extreme size evolution. In all conditions assayed, we found a significant association between proximal upstream single nucleotide polymorphisms and differential gene expression, suggesting a role for *cis*-regulatory evolution in GI metabolism. We identified 91 DE genes within +/- 3Mb of QTL for body size recently mapped in crosses between GI and WSB mice. A subset of these genes harbor fixed sequence differences between GI and WSB mice in potential upstream regulatory regions. This study further establishes the GI mouse as a model for understanding the genetic basis of insular body size evolution and provides candidate genes for potential functional genetic assays that explore variable and abnormal growth and metabolism in vertebrates.

P327 Does the Y-chromosome facilitate sexual dimorphic evolution or constrain autosomal evolution? *I. C. Kutch*, K. M. Fedorka. University of Central Florida, Orlando, FL.

Non-protein coding regions of the Y-chromosome have been shown to influence the expression of hundreds of autosomal and X-linked genes in multiple species. This Y-linked regulatory variation (YRV) may provide the sex-specific variation in gene expression required for the adaptive evolution of sexually dimorphic traits. This requires that YRV exist within natural populations, influence fitness related traits, and be at least in part comprised of additive genetic variation (i.e. selection must be able to shape it). In this study we investigated the ability for selection to

shape YRV using wild caught *Drosophila melanogaster.*

We collected wild *D. melanogaster* from a single locality to investigate the potential for selection to shape YRV. To determine if YRV exists within a population, we introgressed 30 Y-chromosomes into a single genetic background and assayed for variation in immune gene expression. To determine if YRV has any fitness consequences, we then tested these same Y-chromosome lines for differential responses to a real immune challenge. Lastly, we crossed 4 Y-chromosomes into 4 different genetic backgrounds to determine if intra-population YRV was comprised of additive genetic variation.

Our data suggest that intra-population YRV does exist and that this variation is correlated with survival to a bacterial pathogen. Furthermore, the magnitude of the YRV effect was quite large (~42.6% of genetic variation in our experimental lines). However, to our surprise, this variation was comprised entirely of non-additive genetic variation, suggesting that selection may not be able to act on immune-related YRV and may instead act as a significant constraint to the adaptive evolution of insect immune function. The extent to which this non-additive variation is constraining the adaptive evolution of immune response is currently being tested using experimental evolution on more realistic population level variation. Additional traits are also being investigated as it is possible for YRV to manifest differently for different YRV sensitive traits.

P328 The antibiotic-independent evolution of antibiotic resistance. *R. Hershberg*, W. Field, S. Katz. Technion, Israel Institute of Technology, Haifa, IL.

It has been demonstrated that when bacterial colonies are starved, the frequency of antibiotic resistance tends to increase, even in the absence of any antibiotic exposure. We were able to demonstrate that, contrary to widespread assumption, such starvation-induced increases in antibiotic resistance frequencies were not due to increases in mutagenesis. Rather, it appears that specific resistance mutations to a variety of antibiotics are beneficial to bacterial growth under starvation. We could further demonstrate that one such resistance allele that we identified as adaptive under starvation is alarmingly frequent within natural bacterial populations. This antibiotic resistance allele is particularly frequent within-host environments, where on average ~40% of bacteria carry the allele, independent of levels of antibiotic exposure. Our results suggest that the antibiotic-independent fitness effects of resistance alleles may strongly affect the frequency with which resistance segregates within natural bacterial populations.

P329 Dynamics and feasibility of CRISPR/Cas9-mediated gene drives in natural populations. *P. Messer*, A. Clark, R. Unckless. Cornell University, Ithaca, NY.

The idea of driving an engineered gene to fixation in a population is more than 40 years old. Its potential applications are ambitious and widely varied, including the eradication of disease vectors, the control of pest species, and the preservation of endangered species from extinction. So far, all proposed drive mechanisms have fallen short of these goals. The recently developed CRISPR/Cas9-mediated gene drive (CMGD) now promises a mechanism for quickly driving genetically modified alleles to high frequency in a population regardless of their fitness cost. However, we still lack a comprehensive understanding of the population dynamics of CMGD and are therefore unable to predict its spread in natural populations in the face of potential resistance. Here we develop a comprehensive population-genetic model of CMGD to evaluate the feasibility of this process in natural populations. We specifically study the probability that resistance evolves against a gene drive from alleles that (i) are already present as standing genetic variation when the driver allele is introduced into the population, (ii) arise by de novo mutations while the driver allele is spreading through the population, or (iii) are created by the drive itself when double strand break repair results in mutated target sites that can no longer be recognized by the driver's guide RNA. We use these results to analyze how different drive strategies (breaking a gene versus editing/inserting a gene) are expected to influence the probability of resistance due to different fitness costs of resistance alleles. We finally discuss how our results can be used to identify strategies with reduced potential for resistance evolution in order to facilitate a successful drive, as well as approaches that would promote resistance as a possible mechanism for controlling the spread of a drive.

P330 Legacy of James Crow. *Daniel Hartl*. Harvard University, Cambridge, MA.

no abstract submitted

P331 Estimating Jacquard's general model of relatedness from population genomic data. *Matthew S. Ackerman*[1], Parul Johri[1], Ken Spitze[1], Sen Xu[2], Thomas Doak[1], Kimberly Young[1], Michael Lynch[1]. 1) Indiana University, Bloomington, IN; 2) The University of Texas at Arlington.

Population structure is described by genotypic correlation coefficients between individuals, the most basic of which are Jacquard's nine condensed coefficients. These correlation coefficients form the basis of quantitative genetic analysis, and geneticists perform experimental crosses or pedigree analysis in order to recover them. Previously molecular techniques could only recover four of these coefficients, but we can recover seven coefficients using biallelic loci and a maximum likelihood method. This approach should allow for more robust estimation of the components of genetic variance from population genomic data.

Simulations show that the procedure is nearly unbiased, even at the minimally informative 3x coverage, and that errors in five of the seven coefficients are statistically uncorrelated. The remaining two coefficients have a negative correlation of errors, but their sum provides an unbiased assessment of the overall correlation of heterozygosity between two individuals. These methods are applied to four populations of the freshwater crustacean *Daphnia pulex,* and revealed several interesting characteristics that are not apparent with other techniques. The use of a maximum likelihood method also allows us to assess statistical significance of relationships using a log likelihood ratio test, and we find statistically significant negative estimates of many of these pair-wise relatedness coefficients. Although these coefficients are traditionally regarded as measure of the probability of identity, which cannot be negative, we treat them as measures of conditional association, which can

be negative. These methods are implemented as part of the mapgd package (maximum likelihood analysis of population genomic data) available from https://github.com/LynchLab/MAPGD.

P332 Dynamics of seasonal adaptation in *Drosophila melanogaster*. *Emily L. Behrman*[1], Alan O. Bergland[2,3], Dmitri A. Petrov[2], Paul S. Schmidt[1]. 1) University of Pennsylvania, Philadelphia, PA; 2) Stanford University, Stanford, CA; 3) University of Virginia, Charlottesville, VA.

The rate and tempo of adaptation is a fundamental question in evolutionary biology. Evolution is generally considered to be a gradual process and it is unclear if populations can adapt rapidly to environmental selection pressures. Temporal changes in environmental selection pressures across seasonal time may results in traits associated with fitness to vary as a function of season; this may result in seasonal oscillations of traits associated with high fitness that are favorable for reproduction and population expansion (summer) and those that are not and must be endured (winter). Long-term datasets can be used to investigate the association between environmental variance, fitness-related phenotypes and changing allele frequencies that are driven by natural selection and therefore reflect the adaptive process. This provides a long-term empirical investigation of seasonal life history patterns in natural populations of *Drosophila melanogaster* using isofemale lines collected from a temperate orchard over five consecutive years. There are pronounced and repeated changes in phenotypic performance based on temporal change in the genetic composition of the population from spring to fall; the variance in traits across seasonal time is equivalent to measurements across broad geographic distances over 20º latitude. Changes in both the phenotypic and genetic correlations from spring to fall counters the basic assumption of stable covariance over time and suggests that selection acts rapidly to change the genetic architecture of a population. Whole-genome resequencing of the population across seasonal time reveals thousands of SNPs that cycle as a function of season. Seasonal SNPs are associated with the fitness traits are identified based on genome-wide association and their function is evaluated. Environmental data from the study site is used to identify environmental parameters that correlate with the direction and magnitude of observed seasonal phenotypic and allele variation. The results suggest that selection acts in a rapid fashion with cyclic alternating selection by different environmental parameters between winter and summer phenotypes and genes. The fluctuating-stabilizing selection created by alternating selection pressures across seasons may be integral in the maintenance of phenotypic and genetic variation in natural populations.

P333 The fragile Y hypothesis: The role of Y aneuploidy in the evolution of sex chromosomes and genome architecture. *Heath Blackmon*[1], Jeffery Demuth[2]. 1) University of Minnesota, Saint Paul, MN; 2) University of Texas - Arlington, Arlington, TX.

Y-chromosome losses leading to XO sex chromosome systems are common in many male heterogametic groups (approximately 15% of examined species). However despite a clear understanding of how Y-chromosomes are expected to decay our understanding of why some lineages frequently lose Y-chromosomes while others do not is limited. The fragile Y hypothesis proposes that in species with chiasmatic meiosis the rate of Y-chromosome aneuploidy and the size of the recombining region have a negative correlation. The fragile Y hypothesis provides a number of novel insights not possible under traditional models of sex chromosome evolution. Specifically, as the recombining region of the sex chromosomes shrinks increased rates of Y aneuploidy will impose positive selection for 1) gene movement off the Y; 2) translocations and fusions which expand the recombining region; and 3) alternative meiotic segregation mechanisms (achiasmatic or asynaptic male meiosis). We have built a time-calibrated phylogeny for more than 1,000 beetles and have applied comparative methods to understand the tempo and mode of sex chromosome evolution in beetles with chiasmatic and achiasmatic male meiosis. We show that beetles with chiasmatic meiosis lose Y-chromosomes more frequently and that Y chromosome loss is associated with species that have on average smaller recombining regions. Likewise limited data from mammals is also consistent with Y aneuploidy being an important force in the evolution of sex chromosomes and meiotic mechanisms. This hypothesis and our analyses raise doubts about the long-term stability of the human Y-chromosome despite recent evidence for stable gene content in older nonrecombining regions.

P334 Using network theory to infer and analyze population structure from genetic data. *G. Greenbaum*[1], A. R. Templeton[2,3], S. Bar-David[1]. 1) Ben-Gurion Univ., Midreshet Ben-Gurion, Israel; 2) Washington Univ., St. Louis, MO; 3) Haifa Univ., Haif, Israel.

Clustering individuals to subpopulations based on genetic data has become commonplace in many population genetic studies. Inference of population structure is most often done by applying model-based approaches, for example as implemented in the program STRUCTURE, aided by visualization using distance-based approaches such as multidimensional scaling. While existing distance-based approaches suffer from a lack of statistical rigor, model-based approaches entail often unrealistic assumptions of prior conditions, such as that the subpopulations are at Hardy-Weinberg equilibria. We present a novel distance-based approach for inference of population structure using genetic data by defining population structure using network theory terminology and methodologies. A *network* is constructed from a pairwise genetic-similarity matrix of all sampled individuals. The *community partition*, a partition of the network to dense subgraphs, is equated with population structure, i.e. partition to subpopulations. Furthermore, by applying a threshold for removal of weak connections from the network, we can explore the hierarchical structure of the population. The statistical significance of each hierarchical level of structure can be estimated using permutation tests and evaluation of the partition's *modularity*, a network measure for the quality of community partitions. In order to further characterize population structure, we formulate the *Strength of Association* (SA), the strength in which each individual is associated with its assigned community. We develop the *Strength of Association Distribution* (SAD) analysis, in which the SA distributions are interpreted as isolation and gene flow patterns between the subpopulations. We use both simulated data and real data of 11 human groups, extracted from the HapMap project, to demonstrate the applicability of our method. With the human data, the method detected three statistically significant hierarchical levels, corresponding to African/none-African, African/Indo-European/East-Asian, and fine-scale divisions of the population. SAD analysis showed differences in gene flow patterns between subgroups, for example the African-American and Masai groups showed lower association to the African subpopulation, but evidence of more recent gene flow was observed in the African-American SAD. The approach presented here

provides a novel, computationally efficient, model-free method for inference of population structure that does not entail *a priori* assumptions. The method is implemented in the software NetStruct (available at https://giligreenbaum.wordpress.com/software).

P335 Molecular variation across populations of a widespread North American firefly reveals selection on luciferase but not opsins. *Sarah E. Sander*[1], Kathrin F. Stanger-Hall[2], David W. Hall[2]. 1) Cornell University, Ithaca, NY; 2) University of Georgia, Athens, GA.

Why are animal signals so diverse? This question has received intense scrutiny, and both natural and sexual selection have been implicated as important drivers of signal diversity. Under the framework of sensory drive natural selection is expected to favor signals and receptors that maximize signal detection. A corollary of this is that the genes underlying both signal production and reception should show evidence of selection as they evolve to maximize detection. Fireflies are an excellent system in which to study signal and receptor evolution because the primary genes underlying each are known. Fireflies vary in their signal color, but color is not important for female choice, implying that natural selection for detection is the primary driver of color evolution. Sequence variation in luciferase, the enzyme that catalyzes the light reaction, is thought to cause the color differences between species. Likewise, sequence variation in opsins, the protein components of visual pigments, may underlie the variation in visual sensitivity, which has been shown to match signal color, across species. Here we tested the hypothesis that light color is due to selection acting on luciferase and the resulting predictions that (1) sequence variation in luciferase correlates with observed variation in signal color, (2) sequence variation in opsins correlates with observed variation in signal color (and inferred visual sensitivity), and (3) signatures of selection are evident at these two loci. To do this, we sequenced the luciferase and opsin genes of 192 individuals from 12 populations of the North American firefly, *Photinus pyralis*. We also sequenced the *cytochrome oxidase I* (*COI*) locus and genotyped individuals at 716 single nucleotide polymorphisms (SNPs) using triple digest restriction site associated DNA sequencing (3RAD). We tested for selection while accounting for population structure by comparing differentiation (Fst) at SNPs in luciferase and opsins to the distribution of Fst for the genome-wide 3RAD SNPs. We found no variation at the amino acid level in either luciferase or opsins despite the population differences in signal color. However, silent variation in luciferase, but not opsins, shows high levels of differentiation among populations, strongly suggesting that selection is acting at this locus. The absence of protein variation rejects the paradigm that variation in light color is solely due to variation in luciferase sequence in *P. pyralis*. Instead, natural selection appears to target regulatory or other non-coding variants. If natural selection targets light emission color, our work suggests that either non-coding luciferase variation directly alters emission color through an unknown mechanism, or changes at another gene are correlated with changes in non-coding variants in luciferase.

P336 Fitness pleiotropy and the phenotypic basis of adaptation in experimentally evolving yeast. *S. Venkataram*, Y. Li, A. Agarwala, B. Dunn, D. Fisher, D. Petrov, G. Sherlock. Stanford University, Stanford, CA.

Adaptive mutations drive much of the evolutionary diversity observed in nature. Understanding the relationship between genotype, phenotype, and fitness in adaptive mutations is therefore essential to understanding adaptation and evolutionary processes in general. As fitness is dependent on the environment, it is necessary to study the fitness of adaptive mutations across a range of conditions to characterize fitness pleiotropy. We recently developed a DNA barcoding technology to quantify the fitness effects of ~4,800 independently evolved yeast clones. Each clone contains on average a single adaptive mutation and was isolated from an experimentally evolving population under glucose-limited batch culture conditions. We selected several hundred clones possessing adaptive mutations and performed whole-genome sequencing to comprehensively characterize the genetic basis of adaptation-driving mutations in this low-glucose condition and build a genotype-fitness map. In this work, we used this DNA barcode technology and our previously identified adaptation-driving mutations to study both fitness pleiotropy and understand how these mutations affect cell physiology. We re-measured fitness for all 4,800 independent clones under varying growth conditions, where we systematically varied either the amount of time the cells spend in exponential growth or stationary phase within each batch growth cycle. We found strong evidence of fitness pleiotropy across both sets of experiments, as well as instances of antagonistic pleiotropy where many of our adaptive clones became deleterious if they spend too long in stationary phase between batch culture cycles. In addition, fitness pleiotropy was dependent on both the gene and in some cases the mutation type (i.e. missense, nonsense or frameshift) of the specific adaptive mutation. Our sample size and ability to isolate single adaptive events gives us confidence that all of these results are driven by pleiotropy and not by passenger mutations in these strains. Our findings also showed that all of our adaptive mutations modulated multiple phases of the yeast growth cycle, including the exponential and stationary growth phases. We validated our results using detailed physiological studies measuring the growth of the adapted strains in monoculture and growth when competed against the ancestral strain. Surprisingly, our adaptive mutations appeared to generate antagonistic phenotypic effects even within the exponential growth phase, where many adaptive mutations grew more slowly than the wild-type clone early in exponential growth but grew faster than wild-type late in exponential phase. Our results highlight the complex physiological changes that underlie even single adaptive events, and suggest that the genotype-phenotype-fitness map can be modulated by even slight changes in the environment.

P337 Systems genetics for industry: combining QTL mapping, GWAS and RNA sequencing to improve bone strength in laying hens. *D. J. de Koning*[1,2], H. A. McCormack[2], B. Raymond[1], A. M. Johansson[1], R. Preisinger[3], M. Schmutz[3], I. C. Dunn[2]. 1) Swedish University of Agricultural Sciences, Uppsala, Sweden; 2) The Roslin Institute and R(D)SVS, University of Edinburgh, UK; 3) Lohmann Tierzucht GmbH, Cuxhaven, Germany.

Bone fractures are a major welfare problem in laying hens. In order to determine the potential to selectively breed for bone strength, divergent selection lines were established in the nineties from a commercial breeding line of White Leghorns. Bishop et al (2000) showed a heritability of 0.40 for a bone index that combined breaking strength from different bones. Subsequently an F2 was created from G9 of the selection lines and a quantitative trait locus (QTL) with a large effect was mapped on Chromosome 1 (Dunn et al., 2007).

In this study, we refined the QTL in the F2 by adding SNP markers. We then tested the SNPs from the refined region on the 2006 generation of

the White Leghorn line from which the F2 was derived after 9 generations of divergent selection. Subsequently, birds from the 2011 generation were genotyped for the QTL haplotype and birds with alternative QTL haplotypes were selected for qPCR of candidate genes and RNA sequencing.

For the SNPs with the most consistent effects, the tibial breaking strength for the alternative haplotypes in the 2006 population was 200.4 vs 218.1 Newtons ($p<0.002$).

The RNA sequencing showed strong differential expression for a single candidate gene in the QTL region with clear allelic imbalance suggesting a *cis*-acting effect within the candidate gene.

Subsequently, a full GWAS was carried out on ~750 birds from the 2006 generation using the Affymetrix high-density SNP chip. After quality control around 225K SNP remained for a mixed model GWAS using GenAbel. Additional QTL were identified on chromosomes 3, 8 and 16. The most significant QTL on chromosome 8 had an additive effect of 20 Newton. At present we are validating these SNP effects in commercial crossbred layers from different companies, with different feeding regimes and in different housing systems. This will be the ultimate test for the utility of these genetic markers to improve bone strength under practical farming conditions.

P338 Effect of Genetic Architecture and Sample Size on the Accuracy of Genomic Prediction of Complex Traits. *Fabio Morgante*[1], Wen Huang[1], Christian Maltecca[2], Trudy Mackay[1]. 1) Program in Genetics, Department of Biological Sciences, and WM Keck Center for Behavioral Biology, North Carolina State University, Raleigh, NC; 2) Program in Genetics, and Department of Animal Science, North Carolina State University, Raleigh, NC.

Understanding the genetic architecture of complex traits is a fundamental aim of many branches of genetics. Genome wide association studies (GWAS) have been successful at identifying some loci affecting complex traits. However, those loci account for just a very small proportion of the total genetic variation, the widely known phenomenon called “missing heritability”. As a result, prediction of phenotypes based on the loci uncovered by GWAS has had low accuracy. Methods that regress phenotypes on hundreds of thousands of markers concurrently (whole genome regression, WGR,) may be able to capture a consistent amount of the genetic variation of complex traits and, thereby, increase predictive ability. However, most WGR methods assume strict additivity and traits that are potentially affected by non-additive (epistatic) interactions have not shown any gain in predictive ability. Here, we investigated the effect of sample size and genetic architecture on the accuracy of genomic prediction of complex traits. We used G-BLUP methodology and the unique resource of the *Drosophila* Genetic Reference Panel (DGRP), a collection of 205 fully sequenced inbred lines that have been phenotyped for many quantitative traits, as well as simulated data. The results show that the accuracy of prediction increases as the sample size increases, conditional on the genetic architecture of the trait examined being taken into account in the statistical model used. In particular, strict additive models in presence of an epistatic component being part of the genetic architecture may fail completely, even if we have knowledge about the true variants affecting that trait and no matter the size of the sample. However, when an epistatic model is fitted, the accuracy of prediction rises, even with small sample size. In summary, this study shows the importance of accounting for their genetic architecture to increase the accuracy of genomic prediction of complex traits.

P339 A Powerful Yeast Mapping Panel for Complex Trait Genetics. *Daniel A. Skelly*[1], Selcan Aydin[1], Sriram Vijayraghavan[1], John H. McCusker[1], Eric A. Stone[2], Nicolas E. Buchler[1], Paul M. Magwene[1]. 1) Duke University, Durham, NC; 2) North Carolina State University, Raleigh, NC.

Dissecting the genetic architecture of quantitative traits is a formidable challenge in modern biology. Genetic resource populations are a powerful tool for understanding the contributions of alleles segregating in natural populations to variation in quantitative traits. We present the “Yeast Diversity Mapping Panel”, a genetically diverse panel of nearly 800 F2 segregants from crosses between wild, laboratory, and domesticated strains of *Saccharomyces cerevisiae*. This genetic resource population has been carefully designed to capture the bulk of genetic diversity present in budding yeast, maximize allelic richness across the panel, and incorporate ancestry from parental strains that show substantial variability across >250 phenotypic axes. We describe a novel method for computationally deconvolving haplotype blocks from pooled, unbarcoded libraries of genetically diverse segregants, and demonstrate the use of this technique to obtain full genome sequence information for our mapping panel. The resulting high-resolution genotypes can be integrated with patterns of allelic effects to narrow QTL intervals, and will facilitate identification of candidate causal alleles for functional follow-up. We demonstrate the utility of this mapping panel by characterizing the genetic architecture of a quantitatively varying phenotype, growth response to osmotic stress. Overall, this panel constitutes a powerful resource for interrogating the genetic basis of complex trait variation, and will facilitate studies of dynamically variable phenotypes, epistasis, and gene-environment interaction.

P340 Using haplotype-based models for genomic predictions in crossbred animals and multiple breeds. *J. E. Decker*[1,2], M. L. Wilson[1], R. D. Schnabel[1,2], R. Weaber[3], J. F. Taylor[1]. 1) Division of Animal Sciences, University of Missouri, Columbia, MO; 2) Informatics Institute, University of Missouri, Columbia, MO; 3) Department of Animal Sciences and Industry, Kansas State University, Manhattan, KS.

One of the major shortcomings of genomic prediction is the low prediction accuracy across populations. We explore the use of haplotypes, rather than SNP genotypes, as effects in genomic predictions trained to be accurate in multiple populations. We analyzed 651 Angus and 1,095 Hereford purebreds along with 695 Charolais, 283 Limousin, 301 Maine-Anjou, and 516 Simmental sired (with predominantly Angus dams) samples with phenotypes and BovineSNP50 genotypes from the Carcass Merit Project (CMP). We used 3,993 Angus, 101 Charolais, 1,225 Hereford, 2,366 Limousin, 11 Maine-Anjou, and 1,913 Simmental purebred animals in addition to the CMP animals to phase the genotype data and impute missing genotypes using BEAGLE v3. Using GEMMA, we fit traits in a Bayesian Sparse Linear Mixed Model (BSLMM). Core SNPs with

the largest effects were identified from the SNP-based BSLMM analysis. Using the four flanking SNPs to each identified core SNP, we constructed non-overlapping five SNP blocks that were used to form haplotypes. Using GEMMA, we fit this new haplotype matrix as random effects in a BSLMM prediction model. We used two methods to validate these predictions. First, we used a three-fold cross-validation within breeds where clusters were chosen using genomic relationships to maximize relatedness within a cluster and minimize relatedness between clusters. Second, we omitted one breed and trained on the remaining five to assess the model's ability to predict genetic merit in breeds not represented in the training data. Using 500 to 1,000 QTL regions (core SNPs) maximized the correlation between phenotype and predicted breeding value. Results indicate that feature selection maybe more important than the use of haplotypes. When we trained a genomic prediction model with 38,686 SNPs in all breeds, the correlations from three-fold cross validation averaged 0.17 for Hereford. When we trained a genomic prediction model using 22,427 haplotypes representing 1,000 QTLs, the average correlation for Hereford was 0.41. When we trained using the 5,000 SNPs corresponding to the 1,000 QTL regions, the average cross-validation correlation for Hereford was 0.52. When we trained in five breeds omitting Hereford and then validated in Hereford, we observed a correlation of 0.33 for the haplotype model and a correlation of 0.54 for the 5,000 SNP model. Using only the top 5,000 haplotype effects, we achieved correlations of 0.65 for both the three-fold cross validation and the validation when Hereford was excluded from the training set. We have recently genotyped 1,240 additional CMP animals from 5 breeds (Brangus, Gelbvieh, Red Angus, Salers, and Shorthorn) to be used for additional validation. We continue to evaluate models to identify the optimal use of haplotypes in genomic prediction.

P341 Dissection of complex traits in sorghum for the sustainable production of fuels and chemicals. *W. Vermerris*[1], A. Abril[1], T. J. Felderhoff[1], P. S. Rao[1], S. Shukla[1], C. H. Kang[2], S. E. Sattler[3], S. Kadam[4], S. Bardhan[4], F. Fritschi[4]. 1) University of Florida, Gainesville, FL; 2) Washington State University, Pullman, WA; 3) USDA-ARS, Lincoln, NE; 4) University of Missouri, Columbia, MO.

Large-scale cultivation of bioenergy crops on low-productivity land and with minimal inputs of fertilizer and chemicals can contribute to the sustainable production of fuels and chemicals as alternatives to petroleum-derived products. This requires, however, fundamentally different crop improvement strategies than the ones that have been implemented to maximize the yield of commodity crops since the Green Revolution.

Sorghum (*Sorghum bicolor* (L.) Moench), a diploid grass that originated in Africa, is a promising bioenergy crop due to its great yield potential with low input requirements. It is also tolerant to a wide range of growing conditions, due to its great genetic diversity. The availability of the sorghum genome sequence has facilitated genetics and genomics studies.

Genetic improvement of sorghum as a feedstock for renewable fuels and chemicals will benefit greatly from the elucidation of a number of quantitative traits: **1) Disease resistance:** Successful expansion of the crop on low-productivity land, especially in the southeastern United States, depends on resistance against the most prevalent diseases, including anthracnose, a fungal disease that can result in yield losses of up to 70%. Several sources of anthracnose resistance have been identified and we recently fine-mapped two novel, major anthracnose QTL and are currently validating a small number of candidate genes using virus-induced gene silencing. **2) Flooding tolerance:** Production of bioenergy crops on land that is prone to seasonal flooding minimizes competition with food production, but requires plants able to withstand water logging. We have identified a number of sorghum genotypes that can tolerate prolonged flooding by forming aerial roots that float on the water. High-throughput expression profiling of these roots revealed extensive changes to plant metabolism. **3) Cell wall composition:** The efficiency of converting biomass to fermentable sugars is a function of cell wall composition, which can be modified by exploiting natural genetic variation, chemically induced mutants, and transgenic approaches. We have shown up to 30% improvement in the yield of fermentable sugars from biomass by using mutants with altered cell wall composition, cloned the underlying genes, and explained the impact of the mutations via structural analyses, including X-ray crystallography. Detailed understanding of the catalytic mechanisms of these enzymes is now forming the basis for protein engineering studies in which metabolic pathways can be reconfigured to meet specific applications.

This presentation will highlight the main findings of this multidisciplinary approach to dissect these complex traits.

P342 Rediscovering the Diallel: How inbred and F1 data can be used to define, model and estimate heritability of both ordinary and treatment-response traits. *W. Valdar*[1], A. Lenarcic[2], J. Crowley[1], Y. Kim[1], P. Maurizio[1]. 1) UNC Chapel Hill, NC; 2) Securities and Exchange Commission, NY.

The inbred diallel is one of the oldest designs in model organism genetics. Describing the complete (or incomplete) set of F1s produced from a given panel of parental lines, it can be used to cleanly partition different types of heritable effects, from additive, epistatic, parent-of-origin, and sex-specific versions thereof. Since pilot data often corresponds to an incomplete diallel, diallel analysis of such data can powerfully guide selection of follow-up studies. Yet, thanks to a turbulant history marked by racorous disagreements, awkward formulations, and outdated statistical ideas, diallel data is often not analyzed as such -- indeed, diallel analysis is too often treated as an arcane puzzle to be avoided. In our view, this wastes a tremendous opportunity. Motivated by a series of extensive pilot studies on the founders of the Collaborative Cross, we recently revisited diallel analysis from a modern statistical perspective, reformulating the traditional model and approach to leverage what we see as some of the diallel's greatest strengths -- the ability to project into a new design space in order to prioritize follow-up experiments that use genetic combinations of the same parental lines. We have since extended our approach to define and estimate heritable effects on response to an applied treatment, leading to a definition and modeling of GxE that would be almost impossible in human studies. I will first introduce basic concepts of the diallel cross and its decomposition via Bayesian hierarchical modeling; then I will describe how these are extended to model genetic effects on treatment response, illustrating this extension with recent work on understanding the pharmacogenetics of haloperidol treatment, and the immunogenetics of response to flu infection.

P343 A New Trait Mapping Method for *Drosophila* Reveals Oligogenic Adaptation from Standing Genetic Variation. *John Pool*, Justin Lack, Héloïse Bastide, Quentin Sprengelmeyer, Jeremy Lange, Amir Yassin, Dylan Braun, Matthew Monette. University of Wisconsin - Madison, Madison, WI.

Improved genetic mapping approaches are key to a range of biological studies, including investigations of the genetic basis of adaptive trait evolution. Here, we develop a next generation approach to bulk segregant analysis (BSA) in *Drosophila*, using a simulation-based inference framework to deal with overlapping quantitative trait locus (QTL) peaks. Our simulations suggest that BSA yields consistently stronger QTL signals than introgression mapping. We apply this method to traits that differ adaptively between natural *D. melanogaster* populations. These traits include body and wing size in a highland Ethiopian population, and the parallel evolution of melanic pigmentation and ethanol tolerance in three populations each. QTLs of moderate to large effect are readily detectable for each trait, but these often vary among strains from the same population. Examining genetic variation within QTL peaks, we find evidence that local adaptation occurred via selection on standing genetic variation, producing "soft sweep" patterns such as isolated variants with strong population frequency differences. These results begin to crystalize a general model for the genetic architecture of adaptive trait evolution in *Drosophila*. The BSA mapping method introduced here may prove valuable in many studies in *Drosophila* and in other experimentally tractable organisms.

P344 The genomic architecture of interactions between natural polymorphisms and environments in yeast growth. *X. Wei*, J. Zhang. University of Michigan, Ann Arbor, MI.

Gene-environment interaction (G×E) refers to the phenomenon that the same mutation has different phenotypic effects in different environments, and is believed to be common in all organisms. Previous studies in humans and model organisms identified a number of genes or quantitative trait loci (QTLs) exhibiting G×E. However, little is known about the general properties of G×E and its underlying QTLs. Here we use the genotype data of 1005 segregants from a cross between two *Saccharomyces cerevisiae* strains and the growth rates of these segregants in 47 different environments to identify QTLs underlying *g*rowth rate variation in each environment (gQTLs) and QTLs that have different effects in each pair of *e*nvironments (g×eQTLs). We found that 31% of gQTLs are g×eQTLs and on average 78% of g×eQTLs belong to gQTLs, supporting the current practice of identifying genes/QTLs showing different effects in different environments from genes/QTLs with effects in individual environments. Interestingly, most g×eQTLs identified from gQTLs have concordant rather than antagonistic effects in different environments, but as the effect size of a mutation in one environment increases, the probability that it is antagonistic in another environment becomes greater. Antagonistic g×eQTLs are overrepresented in environments rarely encountered by yeast in nature. We found gQTLs to be enriched in nonsynonymous sites and nonsense sites, while g×eQTLs are enriched in introns. Gene Ontology (GO) analysis identified >10 times the number of enriched GO terms for g×eQTLs than gQTLs. Simulations based on the yeast data showed that ignoring G×E causes substantial missing heritability. Together, our findings reveal the genomic architecture of interactions between natural polymorphisms and environments in yeast growth and demonstrate the importance of considering G×E in explaining fitness variation and missing heritability.

P345 How to make drug resistance evolution "difficult": a lesson on epistasis and robustness in malaria parasites. *T. Chookajorn*[1], K. Kumpornsin[1], T. Kochakarn[1], Y. Yuthavong[2], N. White[1,3], D. Fidock[4], O. Miotto[1,3,5]. 1) Mahidol Univ., Bangkok, Thailand; 2) NSTDA, Bangkok, Thailand; 3) Oxford Univ., Oxford, UK; 4) Columbia Univ., New York, NY; 5) Wellcome Trust Sanger Institute, Hinxton, UK.

Drug resistance evolution is an intricate process, requiring a series of epistatic interactions to maintain balance between selective advantage and fitness loss from drug-resistant mutations. The key questions are why treatment with certain antibiotics does not lead to full resistance, and why some drugs can be quickly overcome by drug-resistant mutations. Malaria drug resistance has become an excellent model to study these question since the parasites have been under a plethora of drug regimens for more than a century. Here we used antifolate and artemisinin resistance as models to show that the difference comes from the gain of robustness during the evolutionary process, which allows mutations to be accumulated without fitness loss.

In antifolate resistance, we demonstrated how robustness evolved under selective pressure from an antimalarial drug inhibiting the folate synthesis pathway. A series of four nonsynonymous amino acid substitutions at the targeted enzyme, dihydrofolate reductase (DHFR), render the parasites highly resistant to the antifolate drug pyrimethamine. The stepwise gain of these four *dhfr* mutations results in tradeoffs between pyrimethamine resistance and parasite fitness. The epistatic interactions between *dhfr* mutations and amplification of the gene encoding the first upstream enzyme in the folate pathway, GTP cyclohydrolase I (GCH1) promotes pyrimethamine resistance. *gch1* amplification confers low level pyrimethamine resistance and would thus be selected for by pyrimethamine treatment. Interestingly, the *gch1* amplification can then be co-opted by the parasites because it reduces the cost of acquiring drug-resistant *dhfr* mutations downstream in the same metabolic pathway.

On the other hand, the resistance level of artemisinin, the drug of choice for severe malaria treatment, is relatively low with only clinical presentation of delayed parasite clearance by a few hours. Convergent evolution, driven by multiple trajectories to overcome artemisinin-induced stress, was observed, but it was precluded to become full blown resistance by high fitness cost as shown by unstable resistant phenotypes. Artemisinin-resistant parasites suffered from fitness loss and produced fewer progenies. Under amino acid starvation, the resistant parasites failed to undergo maturation unlike their sensitive counterparts as a result of reduced hemoglobin consumption. The reduction leads to loss in artemisinin sensitivity, but the defect causes significant fitness trade-off. Without the gain of a new robustness system, long-term drug selection experiment failed to drive artemisinin resistance to surpass therapeutic doses, but the selection toward antifolate resistance was quickly and repeatedly accomplished under increased robustness by extra GCH1.

P346 Investigating cryptic genetic variation through position effect variegation in a panel of *Drosophila melanogaster* inbred lines. *J. Y. Kao*[1], D. W. McNelis[1], B. E. Goulet[2], J. Shen[3], M. L. Siegal[1]. 1) New York University, New York, NY USA; 2) Harvard University, Cambridge, MA; 3) Stony Brook University, Stony Brook, NY.

Organisms are constantly adapting and evolving in response to internal and external stimuli. These changes can arise by either new mutations or by genetic variation that was already present in the system. The latter source of standing genetic variation, which does not affect the usual range of phenotypes, but has a potential to modify a phenotype in the event of an environmental or genetic perturbation, is referred to as cryptic genetic variation (CGV). Studying cryptic genetic variation in present times is especially important. Due to the environmental and cultural changes in recent human history, the uncovering of CGV could be a potential explanation for the rising incidences of "diseases of modernity" (i.e. asthma, diabetes, depression, etc.). We believe that cryptic variants are quite prevalent in the genome and do play a significant part in determining the consequences of genetic perturbations in an organism. To demonstrate the release of CGV, we use the fruit fly, *Drosophila melanogaster* and perturb the gene, *His2Av*, which encodes for an alternate histone. Work done in nematode worms and yeast reveal that chromatin regulation may be a factor in suppressing cryptic variation. Additionally, *His2Av* is the ortholog of yeast *HTZ1*, which contributes to robustness of cell morphology against microenvironmental variation and has also been shown to have extensive epistasis with genetic variants present in a panel of yeast mutation-accumulation lines. In our study, we have created a new loss-of-function *His2Av* mutation tagged with GFP and introgressed this mutation via backcrossing into the genetic backgrounds of the Drosophila Genetic Reference Panel (DGRP), which is a panel of naturally-derived inbred *D. melanogaster* lines. We then crossed each of our introgressed lines to the w[m4] line to reveal dominant effects of the *His2Av* knockout in different DGRP genetic backgrounds. The w[m4] line has an inversion on the X chromosome that places the white gene responsible for the red pigmentation in fly eyes next to pericentric heterochromatin thereby creating mottled eyes. We are developing a new image-based position effect variegation assay to characterize the extent of variegation in eye pigmentation. By quantifying the amount of variation in perturbed phenotypic responses within and between DGRP lines as well as with and without the *His2Av* mutation, we can understand the prevalence and behavior of cryptic genetic variation.

P347 The cost of noise in biochemical reactions and the evolutionary limits of cellular robustness. *J. Van Dyken*. University of Miami, Coral Gables, FL.

Finite cell size and the probabilistic nature of biochemical reactions combine to generate substantial cellular "noise", i.e., random fluctuations in molecular abundance. An open question is whether noise affects cell function, and, if so, how and by how much? Here I demonstrate that noise causes a quantifiable loss in cell fitness by slowing the average rate of biosynthesis. The efficacy of selection to suppress noise, however, decays superlinearly with cell size, leading to a stark taxonomic divide between prokaryotes and eukaryotes in the principle design imperatives of genomic and cellular architecture.

Extending previous work, I present an analytical framework for solving the steady-state statistics of molecular species in arbitrarily connected networks of non-linear chemical reactions in mesoscopic volumes, which I validate with extensive stochastic simulations. In general, substrate noise slows the average rate of non-cooperative bimolecular (i.e., Michaelis-Menten or hyperbolic) reactions, including reactions intimately tied to organismal fitness: nutrient uptake and translation. I find that gene expression is unusually sensitive to the cost of noise because, unlike with metabolic reactions, noise-induced slowdown is not buffered by network-level feedbacks. In addition, I find that transcriptional noise directly reduces fitness by slowing the average translation rate. In general, the loss in fitness caused by noise scales inversely with cell size, while random genetic drift scales positively with cell size. Together, the ability of natural selection to suppress noise decays superlinearly with cell size, leading to a stark, cell-size-mediated taxonomic divide in selection pressures for gene regulatory architecture. Greatly weakened selection efficacy in large cells may have facilitated the evolution of transcriptional complexity in eukaryotes as they evolved free of the selective constraints of noise minimization experienced by most prokaryotes. Furthermore, hyperbolic translation kinetics substantially influence the noise statistics of gene expression, with numerous practical implications. In particular, with hyperbolic translation, increasing mRNA/ribosome binding affinity actually reduces protein noise, even as it increases translational bursting. These results thus illuminate the costs of cellular noise, the targets of noise-amelioration, and the evolutionary limits of robustness.

P348 Selection transforms the genetic landscape of Hsp90-interacting variation. *Kerry A. Geiler-Samerotte*[1], Yuan Zhu[1], David Hall[3], Sandeep Venkataram[1], Yuping Li[1], Anisa Noorasa[1], Gavin Sherlock[1], Dmitri Petrov[1], Mark Siegal[2]. 1) Stanford University, Palo Alto, CA; 2) New York University, NY, NY; 3) University of Georgia, Athens, Georgia.

Introduction: The chaperone Hsp90 decreases variation in quantitative traits by buffering the effects of polymorphisms found in nature. This result prompts a question: does Hsp90 increase an organism's robustness to genetic perturbation? The potential for Hsp90 and several other putative buffers to increase robustness to mutation has had a major impact on disease models, quantitative genetics and evolutionary theory. But perhaps Hsp90-buffered mutations are rare, yet appear prevalent in nature because stabilizing selection cannot act efficiently on such mutations. This may allow buffered mutations to persist, while other mutations that have immediate effects on phenotype are purged.

Methods: We measure how Hsp90 inhibition affects phenotypic variation among 174 yeast strains that experienced reduced selection as well as 96 yeast strains that experienced natural or artificial selection. We measure 29 orthogonal quantitative traits related to cell morphology for two million yeast cells in control or Hsp90-inhibited conditions. Ours is the first study to rigorously quantify how Hsp90 influences variance in quantitative traits by using statistics that partition multiple contributions to variance.

Results: Hsp90 tends to *decrease* quantitative trait variation among populations that have been exposed to selection. In contrast, Hsp90 predominantly *increases* quantitative trait variation between yeast strains possessing spontaneous mutations that accumulated under reduced selection.

Conclusions: Hsp90 does not make phenotypes more robust to mutations' effects. Stabilizing selection preferentially allows buffered alleles

to persist, transforming the pool of Hsp90-interacting genetic variation found in natural populations to leave the false impression of robustness.

Other selective regimes: Adaptive evolution may enrich for different types of Hsp90-interacting genetic variation. We very recently tested how Hsp90 influences fitness of 82 yeast lineages that each contain on average a single adaptive mutation in one of eleven genes involved in glucose metabolism. Preliminary results show that the presence and direction of Hsp90-induced changes in fitness depend upon which gene contains the mutation. Understanding how hub proteins, like Hsp90, influence the relationship between genetic variation and quantitative traits, and how selection's sieve enriches for certain relationships, will contribute unique knowledge to the larger goal of mapping genotype to phenotype.

P349 Genetic and cellular architecture of parentally biased seed size determinants. *J. Fitz Gerald*, J. Haymore, C. Manley. Rhodes College, Memphis, TN.

Parental genomic imprinting (PGI) is the selective expression of only one allele after fertilization depending solely on its parent-of-origin. In Arabidopsis, PGI has been characterized in the seed endosperm linking this phenomenon to the provision of maternal resources. Understanding the developmental programs regulated by PGI may provide clues to optimizing breeding strategies for seed size.
Loss of PGI can result in large seeds when maternal silencing is compromised or small seeds when paternal silencing is compromised. In a typical breeding scheme, it might be expected that PGI could lead to parent-of-origin effects or specific maternal/paternal interactions that would be masked as a component of heterosis. For example, the Landsberg *erecta* (Ler) ascension of Arabidopsis has a small seed size, but Ler pollen sires large seeds on a Cape Verde Islands (Cvi) mother. Dissecting these epigenetic effects from heterosis or simple additive effects requires a robust system to examine genome-wide genetic contributions to specific phenotypic effects. This is distinct from the more limited analysis of mechanisms for imprinted gene expression that have been characterized extensively in select genes.
To ascertain the adaptive role of global imprinted gene programs in wild-type plants we are simultaneously assaying the genetic basis for parent of origin effects Ler, Cvi and other ascensions, while exploring the cellular basis for differences in early development. A parental bias is observed in these lines with Ler fathers promoting a transgressive large seed not seen in reciprocal crosses. Using spectral analysis of autofluorescence in the seed, we isolated endosperm from surrounding maternal structures in non-transgenic natural variants. Reconstructed 3D endosperm models show that Cvi development involves an adaxial-abaxial expansion not present in Ler, which restricts expansion on this axis maternally. Ler fathers, however, promote an anterior-posterior expansion.
Using recombinant inbred lines, we are further tracking the parental origins and loci associated with changes in early seed development. Previously characterized QTL have been linked to paternal or maternal effects. Further, geometric morphometrics have been applied to seed shape to better discern if there are independent genetic pathways responsible for aspect of final seed size. We are currently linking these final seed size outcomes to events in early development to better understand the developmental targets of seed size adaptations and the role of PGI.

P350 An X×Y genetic interaction mediates global crossover frequency in house mice. *Beth Dumont*. North Carolina State University, Raleigh, NC.

The rate of recombination is a complex trait, with quantitative variation between individuals shaped by multiple genetic factors. Previously, I identified a large-effect X-linked QTL underlying recombination rate differences between males of two house mouse subspecies, *Mus musculus musculus* (*Mmm*) and *M. m. castaneus* (*Mmc*). Surprisingly, at this locus, the allele conferring the increase in recombination rate derives from the low recombination rate *Mmc* parent. This observation suggests that the native *Mmc* genome harbors at least one recombination rate suppressor that overrides the effect of this recombination-increasing allele. Here, I present multiple lines of experimental evidence to demonstrate that one of these suppressors is on the Y chromosome. Using data from the Collaborative Cross panel of recombinant house mice, I estimate that this Y-linked recombination rate modifier decreases global crossover frequency by ~1 crossover per meiosis. I further show that animals with X^{Mmc}/Y^{Mmm} and X^{Mmm}/Y^{Mmc} genotypes have reduced recombination frequencies, suggesting an antagonistic genetic interaction driven by intersubspecific combinations of alleles on the sex chromosomes. I nominate a pair of homologous, ampliconic, and interacting genes on the X and Y as compelling candidates underpinning these intriguing patterns. Together, these findings suggest that recombination rates may be shaped, in part, by intragenomic conflict and offer new genetic explanations for the striking sex differences in the crossover landscape.

P351 CRISPR-directed mitotic recombination enables genetic mapping without crosses. *Meru J. Sadhu*[1,2], Joshua S. Bloom[1,2], Laura Day[1,2], Elise Pham[1,2], Leonid Kruglyak[1,2]. 1) University of California, Los Angeles, Los Angeles, CA; 2) Howard Hughes Medical Institute, Los Angeles, CA.

Linkage and association studies have mapped thousands of genomic regions that contribute to phenotypic variation in myriad organisms. Narrowing these regions to the underlying causal genes and variants has proven much more challenging, as the resolution of genetic mapping is limited by the local recombination rate. We developed a method that uses CRISPR to build mapping panels with targeted recombination events. We tested the method by generating a panel with recombination events spaced along a *Saccharomyces cerevisiae* chromosome arm, and then by targeting a high density of recombination events to a region of interest. Using this approach, we fine-mapped manganese sensitivity in lab yeast to a single polymorphism in the transporter Pmr1, demonstrating that targeting recombination events to regions of interest allows us to rapidly and systematically identify causal variants underlying trait differences.

Though much of the most interesting phenotypic differences are between species, rather than within species, our understanding of the genetic causes of interspecies differences is very limited, as it is extremely difficult to apply linkage or association studies to interspecies variation. Our novel method builds mapping panels using directed recombination events that occur in mitosis, so it can be used to compare

species capable of forming sterile hybrid diploids. We have generated a mapping panel in hybrids of *S. cerevisiae* and *S. paradoxus*, sister species that are approximately 10% diverged, and used it to map traits that markedly differ between them.

P352 Genetic analysis of an intermediate phenotype for recombination rate variation. *Richard Wang*[1], Beth Dumont[1,2], Bret Payseur[1]. 1) University of Wisconsin - Madison, Madison, WI; 2) North Carolina State University, Raleigh, NC.

During meiosis, chromosomes participate in a delicate choreography, exchanging arms and genetic material in the process of recombination. Recombination occurs in all sexually reproducing organisms, is essential for the proper segregation of chromosomes during meiosis, and shuffles alleles onto new genetic backgrounds. Heritable variation for recombination rate exists among individuals, most of which remains unexplained. To provide insights into the genetic mechanisms governing recombination rate variation, we studied the synaptonemal complex (SC), a proteinaceous scaffold that mediates the pairing of homologous chromosomes during recombination. Rates of recombination are strongly correlated with the length of the SC, forming a material link between genetic distance and a physical structure in the cell.

We focused on the house mouse, a model system in which recombination rate and SC length can be quantified in single cells with immunofluorescent microscopy. We developed a high-throughput method to measure SC length and applied it to cytological images of meiocytes from an F_2 intercross between strains of *Mus musculus musculus* and *Mus musculus castaneus*. With this novel phenotypic data, we mapped three quantitative trait loci (QTL) responsible for variation in SC length – the first known QTL for naturally occurring variation in this trait. Substantial divergence in recombination rate exists between these two subspecies, and previous work (in the same cross) identified loci responsible for this divergence. The QTL with the greatest effect on both recombination rate and SC length lie on the proximal end of the X chromosome. When we mapped QTL for variation in SC length conditioned on recombination rate, we found the locus on the X was no longer significant. This suggests distinct genetic controls underpin these strongly correlated traits. Our results help elucidate the genetic architecture of recombination rate variation and help explain the role that the synaptonemal complex plays in that variation.

P353 Replication timing generates conserved base-substitution mutation rates in concurrently replicated regions of mismatch repair deficient bacterial genomes. *Vaughn Cooper*[1], Marcus Dillon[2], Michael Lynch[3], Way Sung[4]. 1) University of Pittsburgh, Pittsburgh, PA; 2) University of New Hampshire, Durham, NH; 3) Indiana University, Bloomington, IN; 4) University of North Carolina - Charlotte, Charlotte, NC.

Evidence now exists that spontaneous mutation rates are non-uniform within genomes across the tree of life, but the causes and consequences of spatiotemporal variation in mutation rates remain uncertain because precise estimates of genome-wide mutation rates are exceedingly rare. To assess the extent to which base-substitution mutation rates vary within the genomes of bacteria with multiple chromosomes, we carried out mutation accumulation experiments paired with whole-genome sequencing (MA-WGS) in three multi-chromosome bacteria, *Vibrio fischeri*, *Vibrio cholerae*, and *Burkholderia cenocepacia*, and two additional MA-WGS experiments in mismatch repair deficient strains of *V. fischeri* and *V. cholerae*. We find that in the absence of mismatch repair, base-substitution mutation rates vary in a mirrored wave-like pattern on opposing replichores of the large chromosome of *V. fischeri* and *V. cholerae*, where concurrently replicated regions experience similar base-substitution mutation rates. The base-substitution mutation rates on the small chromosome vary less but also tend to follow the patterns of concurrently replicated regions of the large chromosome in both species. We lack a sufficient quantity of base-substitution mutations in the MA-WGS experiments with intact mismatch repair to display significant within genome variation in base-substitution mutation rates, so it is uncertain whether the rates in these studies reflect those of the corresponding mismatch repair deficient MA-WGS experiments. These results support the notion that base-substitution mutation rates vary genome-wide across concurrently replicated regions over the duration of the cell cycle, perhaps owing to the spatiotemporal replication timing program or the conserved nucleoid structure on concurrently replicated bacterial replichores.

P354 Decomposing intra-genomic heterogeneity in mutation bias in coding sequences. *C. Landerer*, M. A. Gilchrist. University of Tennessee, Knoxville, TN.

Synonymous codon usage differs not only between taxa but also within a single genome. Current studies of codon usage bias (CUB) attribute any heterogeneity to variation in selection bias for translational efficiency proportional to gene expression. However, these approaches ignore heterogeneity in mutation bias which is widely known to occur. Previously, we have shown that one can decouple the forces shaping CUB and estimate mutation bias, gene expression and selection bias using a Bayesian framework. Here we extend our approach to allow mutation and selection bias to vary between gene categories according to the cellular conditions shaping CUB. We applied our approach to the yeast *Lachancea kluyveri* which provides a striking example of heterogeneity in GC-content. Specifically, the left arm of chromosome C (C-left) has a 13% increased GC-content compared to the rest of the genome. When all genes are assigned to a single category, the model performs overall reasonably well predicting gene expression ($\rho = 0.58$) but shows anomalous behavior for genes located at C-left. In contrast, when grouping the C-left genes into a separate category the anomalous behavior is resolved and prediction of gene expression improves substantially ($\rho = 0.68$). Our extension allows to categorize genes by mutation and selection bias on CUB and current work is focused on automatic categorization of genes.

P355 Transposon-induced genome rearrangements in maize: mechanisms and genetic impacts. *T. A. Peterson*[1], J. Zhang[1], D. Wang[1], T. Zuo[1], W. Su[1], S. P. Sharma[1], D. F. Weber[2]. 1) Iowa State Univ, Ames, IA; 2) Illinois State Univ, Normal, IL.

Barbara McClintock showed that Transposable Elements (TEs) not only move within the genome, but they can also induce major changes in genome structure and gene expression. How do these changes occur? We are studying the mechanisms by which DNA transposons duplicate and rearrange sequences, ranging from individual genic components (enhancers and exons), up to segments of 15 Mbp and containing 300

genes or more. The highly active maize *Ac/Ds* transposon system can undergo Alternative Transposition (AT) reactions that involve the termini of different nearby TE copies: 5' and 3' termini in direct orientation can undergo Sister Chromatid Transposition to produce flanking deletions and inverted duplications; while termini in reversed orientation can undergo Reversed-Ends Transposition reactions resulting in inversions, deletions, translocations and duplications (Zhang et al., 2009, 2013). *Ac/Ds* elements preferentially insert into genic regions, which greatly enhances the frequency of exon shuffling events. We show that *Ac/Ds* transposons can, in a single step, create new chimeric genes which are expressed and produce functional products and visible phenotypes. In addition, AT events that occur during DNA replication generate novel Composite Insertions by DNA re-replication (Zhang et al., 2014). These Composite Insertions can carry enhancers that induce ectopic expression of nearby genes. AT reactions are not unique to *Ac/Ds* elements, but occur also in other *hAT* family transposons which are widespread in eukaryotes. Our results demonstrate that AT events can be an effective mechanism for the generation of new genes, and provide new insight into the impacts of transposable elements on genome evolution.

For animations of Alternative Transposition, see http://thomasp.public.iastate.edu/transposition.html.

P356 Evidence for the interspecies transfer of a driving X chromosome. *C. Leonard*[1], Z. Fuller[2], R. Young[1], S. Schaeffer[2], N. Phadnis[1]. 1) University of Utah, Salt Lake City, UT; 2) Pennsylvania State University, State College, PA.

Segregation distorters are selfish genetic elements that gain an evolutionary advantage by fundamentally violating Mendel's Laws of inheritance. Such distorting systems are found in a wide swath of eukaryotes and powerfully bias segregation ratios in their own favor. When sex chromosomes gain distorting elements, massive shifts to the population sex ratio may even drive populations or species to extinction. While the selective advantage for selfish segregation is obvious, the origins of these distorting chromosomes have proven much more enigmatic.

The *Sex-Ratio* (*SR*) chromosomes in *Drosophila pseudoobscura* and its sister species *Drosophila persimilis* are classic cases of distorting X chromosomes. Males that carry these distorting X chromosomes produce almost exclusively X-bearing sperm, disrupting the sex ratio of their progeny. These SR chromosomes exist as stable polymorphisms in wild populations; neither species has acquired suppressors to counter distortion in males. Perhaps most fascinating is the observation that the *D. persimilis* SR (DperSR) chromosome lacks a large inversion acquired on the standard *D. persimilis* X (DperST) chromosome, causing it to be collinear with the standard chromosome of *D. pseudoobscura* (DpseST). This collinearity is nearly or entirely complete, and it has been mapped down to a short array of repeats at either breakpoint. The simplest explanation for this strange collinearity between DperSR and DpseST is that the DperSR chromosome may have been derived through re-inversion at the same breakpoints to restore collinearity with DpseST.

Surprisingly, our results show that this is not the case. A sliding window phylogeny test across the X chromosome shows that DperSR clearly clusters with DpseST, forming a monophyletic group across species. This clustering is specifically found at the chromosomal inversion breakpoints, where recombination between DperSR and DperST is heavily limited. Through further statistical methods designed to detect gene flow between populations, we detect robust signatures of introgression between DpseST and DperSR. Together, our data suggest a recent origin for *D. persimilis* SR chromosome through transfer from *D. pseudoobscura*. While gene flow across species is halted by hybrid incompatibilities, this chromosome may have persisted in its sister species through its ability to distort. Thus, while distorting elements have been implicated in generating hybrid incompatibility, our work indicates that segregation distorters may also promote gene flow across species by conferring a strong selective advantage to an otherwise deleterious genotype.

P357 The mutational structure of metabolism in *Caenorhabditis elegans*. *Charles F. Baer*[1], Armand Leroi[2], Sarah K. Davies[2], Rodrigo Liberal[2], John W. Pinney[2], Austin Burt[2], Jacob G. Bundy[2]. 1) University of Florida, Gainesville, FL; 2) Imperial College, London.

We investigate the mutational structure of the *Caenorhabditis elegans* metabolome by means of a mutation accumulation experiment. We find that pool sizes of 29 metabolites vary greatly in their vulnerability to mutation, both in terms of the rate of accumulation of genetic variance (the mutational variance, VM) and the rate of change of the trait mean (the mutational bias, ΔM). Strikingly, some metabolites are much more vulnerable to mutation than any other trait previously studied in the same way. PCA provides strong evidence that metabolite pools are genetically correlated, although we cannot statistically assess the strength of correlations between individual metabolites. Some metabolites are also significantly correlated with fitness. Given this structure, we hypothesized that the sensitivity of a metabolite to mutation might depend on its position in the metabolic network. To test that hypothesis we reconstructed the *C. elegans* metabolic network from genomic data, but find that its topology does not predict either the rate of accumulation of mutational variance or the direction and/or magnitude of the mutational bias. We suggest that the observed patterns depend on higher level regulatory interactions that are not captured by simple metabolic network properties.

P358 Ongoing duplicate gene resolution shapes diversified metabolic networks: a functional comparative study of two yeast *GAL*actose utilization networks. *Meihua Christina Kuang*[1,2], Paul Hutchins[3], Joshua J. Coon[3], Chris Todd Hittinger[1]. 1) Department of Genetics; 2) Graduate Program in Cellular and Molecular Biology; 3) Department of Chemistry, University of Wisconsin-Madison, Madison, WI.

After being fixed in a population, duplicate genes continuously diverge and diversify in different lineages. Duplicate gene diversification impacts gene network evolution, as well as organismal traits. Here we demonstrate that ongoing diversification of two duplicate gene pairs from the whole genome duplication shaped different network architectures and resulted in different parameters for galactose metabolism. We functionally compared the *GAL*actose utilization networks between *Saccharomyces cerevisiae* (*Scer*) and *Saccharomyces uvarum* (*Suva*) and found that the resolution of duplicate fate in this network is ongoing in this genus. The first pair, descended from an ancestral kinase and co-inducer, *ScerGAL1* and *ScerGAL3*, are almost completely subfunctionalized in *S. cerevisiae*, with *ScerGAL1* encoding a kinase with weak co-

inducing activity and *ScerGAL3* encoding a dedicated co-inducer without kinase activity. However, we found that, in *S. uvarum*, *SuvaGAL1* can largely complement the removal of *SuvaGAL3*, while *SuvaGAL3* encodes an inefficient kinase and a co-inducer. Another duplicate pair, *GAL80* and *GAL80B*, encodes two partially redundant *GAL* gene repressors in *S. uvarum*, but *GAL80B* has been lost in *S. cerevisiae*. In contrast to the well-established rapid growth of a *S. cerevisiae gal80*-null mutant in galactose, the *S. uvarum gal80*-null double mutant (*gal80Δ gal80bΔ*) shows initial rapid growth followed by several hours of temporary growth arrest. Surprisingly, closer examination revealed that the *S. cerevisiae gal80Δ* mutant also shows a temporary growth arrest, but to a much lesser extent. We found that this arrest is likely caused by overly rapid galactose catabolism, which leads to excessive accumulation of reactive oxygen species. Differences between the severity of growth arrest in *S. cerevisiae* and *S. uvarum* can largely be explained by differences at the *GAL1* locus. Due to technical limitations in detecting the relatively mild effect in *S. cerevisiae*, this novel observation was not captured by decades of research. Instead, the evolutionary differences between closely related model species rendered this general phenotype more conspicuous and facilitated its discovery. Further examination of *gal80*-null mutants of both species in a mixture of galactose and fructose or mannose revealed a stronger growth arrest, which indicates a possibly general metabolic conflict with the rapid co-utilization of galactose with fructose and mannose. Our study provides clear evidence that ongoing differential resolution of *GAL* gene duplicates shaped metabolic network diversification and revealed novel principles of galactose metabolism that might shed light on tradeoffs in carbon metabolism more broadly.

P359 Young proteins are less ordered, showing preadaptation for *de novo* gene birth. *Ben Wilson*[1], Scott Foy[1], Rafik Neme[2], Joanna Masel[1]. 1) University of Arizona, Tucson, Arizona USA; 2) Max Planck Institute for Evolutionary Biology, Plon, Germany.

Occasionally, new protein-coding genes arise *de novo* from noncoding DNA and not from duplication and divergence of other genes. *De novo* originating proteins will be restricted to the taxa that persist following the emergence of the new protein-coding gene: older *de novo* protein-coding genes will have homologs in more distantly related taxa whereas younger *de novo* protein-coding genes may be restricted to few closely related taxa. The historical progression of *de novo* protein-coding genes---from noncoding sequence to presence in a single species to presence in multiple taxa---has led to the theory that proteins should fall along a "continuum" where the traits of the youngest proteins should more closely resemble those of noncoding sequence than those of older proteins, as would be expected if protein-coding genes emerged entirely by chance. An alternative “preadaptation” theory predicts that the youngest proteins will have extreme gene-like trait values because selection will remove all toxic noncoding sequences, which never go on to persist as protein-coding genes. These trait values may even be more exaggerated in younger proteins than in older proteins that have had more time to evolve subtle solutions to structural constraints. We examined intrinsic structural disorder (ISD) as a trait with the potential to distinguish between the competing theories. We inferred ISD from the sequences of all mouse proteins and paired intergenic noncoding sequences after assigning evolutionary ages to each mouse protein via homology-based phylostratigraphy. We found that younger proteins have a higher intrinsic structural disorder (ISD) than older proteins, and proteins translated from intergenic noncoding sequences have the lowest ISD, contradicting the continuum theory of *de novo* gene birth and confirming the alternative theory of preadaptation. Our results are robust to homology detection bias (*i.e.* to evolutionary rate as a confounding factor), to non-genes erroneously annotated as species-specific proteins, and to correcting the flawed but common practice of exaggerating statistical significance by treating genes, rather than gene families, as independent data points.

P360 Lineage dynamics in adapting yeast populations. *J. Piper*, M. Desai. Harvard University, Cambridge, MA.

Predictions of evolutionary outcomes based solely on genome sequence data is limited in experimental evolution studies. Gene-level parallelism that results in differing fates across populations and mutational cohorts formed via hitchhiking obscure our ability to assign likelihoods as to which lineages will survive. Furthermore, while initial fitness has been shown to be a strong predictor of final fitness in adapting laboratory populations of microbes, it is unknown how this phenomenon arises from a system's underlying genomic and physiological architecture when significant sequence-level stochasticity is observed. Here we explore the relationship between genotype and fitness by examining genealogies from a previous long-term evolution study in S. cerevisiae, in which whole-populations were whole-genome sequenced at various time-points over 1000 generations of evolution. We selected a spread of populations representative of observed dynamics in genomic sequence (hard sweeps, clonal interference, etc) and parallelism in mutation identity. We then isolated clones from whole population samples and performed whole genome sequencing and fitness measurements. Using the resulting genealogies and their associated fitness data, we examine the various population genetics factors resulting in the lineage dynamics of adaptation in this system.

P361 Exploration of bioactive peptides from random sequences: an experimental approach to *de novo* gene evolution. *R. Neme*, C. Amador, B. Yildirim, E. McConnell, D. Tautz. Max Planck Institute for Evolutionary Biology.

The biological sequence space is the theoretical representation of all possible combinations of residues to form a protein or nucleic acid. Among the many possible combinations we can identify those which already have functions in many modern organisms.

De novo genes arise from transcribed/translated non-genic sequences known as "protogenes". While the number of protogenes appearing over time is large, only a few become truly functional genes. We suspect this to be closely related to the distribution of possible functions along random unexplored sequenced space.

We have devised a high-throughput system to screen millions of random proteins *in vivo* for their evolutionary potential and biological activity. We are able to recreate and control a phase of the evolution of new genes that has been difficult to approach through comparative genomics alone.

Preliminary results show that a large fraction of random sequences could have activities relevant to the fitness of the host. This enables us to directly explore the functional sequence space to understand a great variety of aspects of molecular innovation.

P362 Molecular evolution and population dynamics of herbicide resistance in *Amaranthus palmeri*: rapid proliferation of a highly conserved gene modulated by population structure. *A. Lawton-Rauh*[1], K. E. Beard[1], J. D. Burton[2], R. L. Nichols[4], N. R. Burgos[3]. 1) Clemson University, Clemson, SC, USA; 2) North Carolina State University, Raleigh, NC, USA; 3) University of Arkansas, Fayetteville, AR USA; 4) Cotton Incorporated, Cary, NC USA.

Gene copy number proliferation is one mechanism amongst several involved in the evolution and spread of resistance. Pinning down the relative impact of gene copy number proliferation and generalized stress response pathways remains elusive due to phenotype complexity and modulation of selection pressure over spatio-temporal scales. Furthermore, specific genomic process(es) underlying rapid adaptive evolution during resistance, particularly copy number multiplication-mediated resistance at the population level, has been difficult to capture. To understand the genomic origins of gene copy number proliferation during increased resistance amplitudes and the subsequent population level processes expanding resistant biotypes, we investigated genus Amaranthus and populations of the species with the most rapidly spreading resistance, *Amaranthus palmeri*. The primary mechanism underlying glyphosate resistance in *A. palmeri* is massive duplication and random spread of *EPSPS* gene copy numbers across the genome. *EPSPS* produces 5-enolpyruvylshikimate-3-phosphate synthase, an essential enzyme in the aromatic amino acid biosynthesis pathway. Outside of glyphosate-resistant biotypes of some species, *EPSPS* is present in single copy, is highly conserved, and contains a binding domain that is the target site of glyphosate across genus Amaranthus, in ancestral *A. palmeri*, and other plant families. In this study, we estimated *EPSPS* gene copy numbers, EPSP synthase abundances, glyphosate resistance bioassays, and genetic population structures of *A. palmeri* across the southeastern U.S.A. We then compared the divergence population genetics profiles of effective population sizes, divergence times, and the rates and patterns of gene flow of *EPSPS* versus randomized non-target genes. Our results indicate independent origins of glyphosate resistance in *A. palmeri* and that recently-founded resistant populations have differing levels of variance in massive amplification of the *EPSPS* gene (from ancestral single copy state to upwards of 400 copies). This multi-population study of *A. palmeri* with differing levels of glyphosate resistance and genetic structures indicates gene amplification as a dominant source of resistance in some populations in contrast to other, more generalized stress response processes in other populations. Taken together, there seems to be alternative routes of glyphosate resistance in *A. palmeri* which may, in part, be shaped or modulated by population structure.

P363 Secreted Proteins evade the Expression – Rate Anticorrelation. *Felix Feyertag*, Patricia M. Berninsone, David Alvarez-Ponce. Univ. of Nevada, Reno, NV.

The evolutionary rate of proteins can vary by orders of magnitude, both between and within species. A primary factor influencing protein evolutionary rate is protein expression level. A strong negative correlation between expression level and evolutionary rate exists in all studied organisms (the so-called E−R anticorrelation). The translational robustness hypothesis proposes that the main underlying cause of the E−R anticorrelation is the deleterious effect of proteins misfolding due to mistranslation. According to this hypothesis, highly abundant proteins are under strong selective pressure to fold correctly despite translation errors. The misinteraction avoidance hypothesis proposes that highly expressed proteins are under stronger selective pressures in order to avoid unspecific protein-protein interactions. In this study we investigate the E−R anticorrelation in secreted proteins, and find that, in contrast to intracellular proteins, the anticorrelation is weaker and/or non-existent in secreted proteins. We calculated the evolutionary rate of all human proteins from comparison with their mouse orthologs, and divided them into secreted (N = 2279) and non-secreted (N = 13567). In accordance with previous studies, we observed a significant E−R anticorrelation for non-secreted proteins (ρ = -0.259, $p = 4.56\times10^{-181}$); however, for secreted proteins this anticorrelation was not observed (ρ = 0.038, p = 0.084). We confirmed this apparent contradiction to the E−R anticorrelation amongst the class of secreted proteins by repeating our analyses using protein abundance data for 6 individual human tissues, and mRNA abundance data for 32 human tissues. In all cases, the E−R anticorrelation was weaker among secreted proteins. Furthermore, we made similar observations in other species, finding that the E−R anticorrelation is weaker in secreted proteins than in non-secreted proteins in *C. elegans*, *D. melanogaster*, *S. cerevisiae*, *A. thaliana* and *E. coli*. We will discuss how the secretory pathway may reduce the selective pressures of misfolding and misinteraction, thus providing possible explanations as to why the E−R anticorrelation is observed in non-secreted proteins but not in secreted proteins.

P364 The fitness landscape of a tRNA gene. *C. Li*[1], W. Qian[1,2], C. Maclean[1], J. Zhang[1]. 1) University of Michigan, Ann Arbor, MI; 2) Chinese Academy of Sciences, Beijing, China.

Fitness landscapes describe the genotype-fitness relationship and represent major determinants of evolutionary trajectories. However, the vast genotype space, coupled with the difficulty of measuring fitness, has hindered the empirical determination of fitness landscapes. Combining precise gene replacement and next-generation sequencing, we quantify Darwinian fitness under a high-temperature challenge for over 65,000 yeast strains each carrying a unique variant of the single-copy tRNA gene at its native genomic location. Approximately 1% of single point mutations in the gene are beneficial, while 42% are deleterious. Almost half of all mutation pairs exhibit significant epistasis, which has a strong negative bias except when the mutations occur at Watson-Crick paired sites. Fitness is correlated with the predicted fraction of correctly folded tRNA molecules, revealing a biophysical basis of the fitness landscape.

P365 The Critical Functions Encoded by Synonymous Sites. *H. Machado*[1], D. Lawrie[2], D. Petrov[1]. 1) Stanford University, Stanford, CA; 2) University of Southern California, Los Angeles, CA.

Although synonymous sites have historically been considered neutral, and are still used as a neutral reference for many analyses, several processes are known to exert a selective pressure on synonymous sites. Despite evidence for selection on synonymous sites across species and for several different processes, the extent of selection on synonymous sites and the relative contributions of the selective processes are not well understood. Using genome sequence data from two *Drosophila melanogaster* populations, we perform a SFS-based maximum likelihood

estimation of purifying selection on fourfold degenerate synonymous sites using short introns as a neutral control. We estimate that ~15% of fourfold sites are under strong purifying selection. We find that the selection can largely be explained by codon bias and splicing-related factors. If preferred codons and alternatively spliced genes are excluded from the analysis, we find no evidence for selection, and recover the short intron level of polymorphism. These results clearly identify the major processes contributing to purifying selection on synonymous sites, and have implications for creating a neutral reference for other species.

P366 Estimation of Population Phylogeny in an IM framework, with Applications to African Human Hunter Gatherer Populations. *J. Hey*[1], A. Sethuraman[1], J. Lachance[2], S. Fan[2], S. Tishkoff[2], Y. Wang[3,4]. 1) Temple University, Philadelphia, PA; 2) University of Pennsylvania, Philadelphia, PA; 3) Rutgers University, Piscataway, NJ; 4) Ancestry.com, Provo, UT.

A new approach for estimation of population phylogeny together with a demographic model of population sizes and migration rates is presented. By including population phylogeny in a general Isolation-with-Migration (IM) model we address a long-standing problem in population genomics. The method utilizes a Markov chain Monte Carlo simulation over both genealogies and population phylogenies and provides a maximum posterior probability estimate of the population phylogeny by integrating over demographic history. By including an unsampled ghost population as an outgroup in the phylogeny, the method accounts for many kinds of interactions between sampled and unsampled populations. We applied the new method to genomic data from Human hunter gatherer populations from Africa. .

P367 The genetic diversity of a population experiencing selection. *Ivana Cvijovic*, Benjamin Good, Michael Desai. Harvard University, Cambridge, MA.

Empirical studies have uncovered significant evidence for selection in natural populations, but a rigorous characterization of these selection pressures has been difficult. The main reason for this gap is the lack of theoretical predictions for the distortion in genealogies caused by selection, except in a few restricted scenarios: when all mutations are either weakly selected, or have a single effect size. In reality, mutational effects often span several orders of magnitude, but it is impossible to account for this in current theoretical models. In these circumstances, selection leads to correlations between the mutational and genealogical processes that cannot be accounted for by analogy with a population with a stable geographic structure. We describe a new coalescent framework that naturally accounts for these correlations by grouping individuals with the same nonsynonymous mutations into genotypes and considering the dynamics of these genotypes first. We show how our approach naturally extends to purifying selection due to a broad range of fitness effects and predicts patterns of neutral variation. This scheme is significantly more accurate than existing theoretical methods based on reductions in the effective population size and significantly more efficient than the alternative of whole-chromosome simulations. In particular, we show that, in certain scenarios, the genetic diversity of a population steadily declines as the size of the population increases, in contrast to predictions from the background selection limit. We give quantitative predictions for the distortions in the genealogies and patterns of genetic diversity depend on the size of the population, mutation rate and the full distribution of selective effects. Our results have important practical implications for the interpretation of natural sequence variability and the characterization of selective pressures in natural populations.

P368 Estimation of effective number of stem cells in Dugesia worms using temporal variance of allele frequencies. *H. Asgharian*, J. Dunham, T. Kitapci, S. Nuzhdin, P. Marjoram. University of Southern California, Los Angeles, CA.

We applied population genetic theory and statistical analysis to study the mechanism of body regeneration in Planarian flatworms. Several species of Planarians have regained attention in recent years owing to their extraordinary capacity for reconstructing whole bodies from small tissue fragments - promising to be extremely informative towards the efforts in regenerative medicine. It is estimated that stem cells comprise about 30% of their body but details of the regeneration process are largely unknown. For example, it is not clear if all stem cells or only a fraction of them close to the wound site participate actively in each round of regeneration; or whether different stem cells contribute almost equally to the growing body. Due to unavailability of transgenes for these species and lack of a high quality reference genome, many routine molecular and cell biology techniques cannot be applied to this system yet. We modeled each cell as a separate individual and the body of a worm as a population of cells. We tried to estimate the effective number of stem cells based on the temporal variance of allele frequencies across 16 generations sampled every other generations. Preliminary results proved that sequence data contain sufficient information to make the desired estimates, and generated an initial estimate of effective stem cell numbers equal to ~1.58X the number of cell generations between first and last samples (lower bound in our dataset: 22.1, more reasonable estimate is in the order of several hundred). This is a much lower number than the estimated total number of stem cells in the body indicating activity of a small fraction of them at each regeneration cycle. This project yields results to improve our understanding of body regeneration through stem cells, and emphasize the utility of out-of-the-box approaches to research when common methods fail.

P369 Estimating ages of singletons and other rare alleles. *A. Platt*, J. Hey. Temple University, Philadelphia, PA.

The ages of different variants segregating in the human population is a topic of considerable current interest. In a typical population genomic sample, however, a full half of the identified variants are present in only a single copy. Existing methods that estimate ages based on allele frequencies can only assign all of these variants to a single, yougest, age class, and methods based on the decay of linkage disequilbrium or shared haplotypes surrounding rare alleles are inapplicable. This leaves this largest class of variants almost completely uncharacterized.

There exists, however, real information in a population genomic sample that will allow us to estimate the ages of individual singleton alleles. In an infinite sites model where each allele has a unique origin, the mutation that created an allele found in a singleton must post-date the most recent common ancestor shared between the individual carrying the singleton allele and any other individual in the sample. We

propose an estimate of the time since this common ancestor as a function of the maximum length of haplotype shared between the individual containing the singleton allele and any other individual in the sample. Conditional on the age of this ancestor, the probability distribution of the age of the allele is uniform over the open range (0, age of ancestor) and has an expected age half that of the common ancestor.

This estimator applies not just to singletons, but any rare allele. For alleles present in multiple copies we use the singleton model to generate a composite likelihood estimate of the age of the most recent common ancestor shared between all of the individuals carrying the allele and any of the other individuals in the sample. This estimate will be more a more precise than in the singleton case due to combining the estimates from multiple observations. Furthermore, previous methods for estimating the age of the most recent common ancestor of the individuals who share the allele refine the estimate of the age of the allele itself to a uniform density over the interval (age of ancestor among carriers, age of ancestor between carriers and others).

P370 Genetic Interrelationships between Zika Virus, Dengue Virus, Chikungunya Virus and Yellow Fever Virus Strains. *Olaitan Awe*[1], Angela Makolo[1], Segun Fatumo[1,2]. 1) University of Ibadan, Ibadan, NG; 2) Wellcome Trust Sanger Institute, Wellcome Genome Campus, Hinxton, Cambridge, CB10 1SA, UK.

Zika virus is an arbovirus in the family Flaviviridae, genus Flavivirus and this virus generally causes a mild febrile illness with maculo-papular rash and paralysis-causing Guillain-Barré syndrome in infected humans. Its main vectors are Aedes mosquitoes, the same type of mosquito that spreads dengue, chikungunya and yellow fever virus. In 2015, Zika virus disease outbreak was reported in South America, with an association of Zika virus infection with microcephaly-babies born with abnormally small heads. This link is based on the surge in microcephaly cases following this outbreak. Nevertheless, little is known about the genomics of Zika virus or its interrelationships with other arboviruses, and treatment is currently based on dealing with the symptoms, but an extensive phylogeny is a step towards a better understanding of the natural history of Zika virus. In this study, we did comparative genomics of certain arboviruses, so as to investigate their genetic interrelationships by obtaining complete genome sequences of Zika, Dengue, Chikungunya and Yellow Fever virus species from Genbank and revealed Zika's phylogenetic position. Results from our analysis revealed that the degree of relatedness in recent Zika virus strains is higher than past Zika virus strains isolated before, and this informs possible genetic changes. We also have a view of the outbreak that started last year in Brazil. We see genetic changes that separate the Brazilian strain of Zika virus from the past strains isolated before. Though, we do not know if there are genetic variations or mutations that have happened within the course of the Zika outbreak event, or mutations within individuals, unless confirmed experimentally. If the virus incurs a mutation, this could also facilitate transmission by another vector. These are important points to put in perspective, developing tools, drugs or having understanding of Zika virus pathogenesis, because these tools are mostly built on the genome sequence of the virus. These Zika strains carry derived mutations which put them in a group with Chikungunya and Yellow Fever Virus, though Chikungunya and Yellow Fever Viruses are more closely related to each other than to Zika. Though, it is hard to speculate on the implications of our results without a few more samples, insights from this study will ultimately help to build the genomic infrastructure needed to study and combat Zika virus. Results from this study could facilitate effective vaccine production pipelines in future. We expect this study to provide better understanding of the genomic knowledge of Zika virus.

P371 Beneficial mutations improve fitness in a *Caenorhabditis elegans* line evolved under conditions of extreme genetic drift. *S. Christy*, S. Estes. Portland State University, Portland, OR.

Most newly arising mutations are deleterious for organismal fitness, yet can readily propagate within populations under a broad range of conditions. Evolutionary genetic processes able to counteract deleterious mutation accumulation include: a) generally beneficial mutations that improve organismal fitness irrespective of genetic background, b) compensatory mutations that specifically mitigate the effects of previously-acquired deleterious mutations through epistasis, and c) reversion mutations back to wildtype. The potential for spontaneous mutations to mitigate the effects of deleterious mutations alters our expectations for the population-level impact of deleterious mutation. However, the capacity of spontaneous mutations to restore ancestral phenotype and the molecular genetic patterns of compensation are still poorly understood in eukaryotic systems. We performed a mutation accumulation (MA) experiment—where mutations are allowed to accumulate in replicate lineages evolving in population sizes of one (i.e., extreme genetic drift)—using a mitochondrial-deficient mutant strain of *Caenorhabditis elegans* nematode, *gas-1*. This strain has lower levels of fitness compared to wildtype. Mutation accumulation is expected to result in further fitness decline due to accumulated deleterious mutations. However, the lines experienced partial phenotypic recovery back to wildtype levels. Next-generation sequencing and bioinformatic analyses revealed several candidate single nucleotide polymorphisms (SNPs) responsible for this recovery. The purpose of this study was to determine the capacity of SNPs to restore fitness in *gas-1*. We introgressed the SNPs onto wildtype and *gas-1* backgrounds, then performed life-history assays to compare the introgressed strains with wildtype and *gas-1* strains. We discovered that the introgressed strains experience a shift to earlier reproduction compared to wildtype and *gas-1* strains and conclude that the SNPs are generally beneficial for fitness. This finding indicates that beneficial mutations are able to accumulate under extremely unfavorable population genetic conditions.

P372 Homoploid hybrid speciation in the wild: yeasts do it too. *G. Charron*[1], J.-B. Leducq[2], L. Nielly-Thibault[1], C. Eberlein[1], C. R. Landry[1]. 1) Université Laval, Québec City, Canada; 2) Université de Montréal, Montréal, Canada.

Hybridization is a powerful mechanism to generate biodiversity, for instance through species formation. However, well-supported cases of homoploid hybrid speciation limited to plants and animals, which indicate that either unicellular eukaryotes have been overlooked or that this mechanism is restricted to multicellular organisms. Experiments in the laboratory have shown that new yeast species can be formed by hybridization, suggesting that this mechanism could be, in principle, observed in nature. Using population genomics, experimental crosses and

fitness assays, we show that homoploid hybrid speciation took place recently in natural populations of *Saccharomyces paradoxus* inhabiting the North American temperate forests. We find (1) reproductive isolation between hybrid and parental species, (2) evidence of hybridization in the genome, and (3) a link between hybridization and reproductive isolation. In addition, we found that the hybrid lineage displays specific growth phenotypes that may reflect a new ecological niche. Our results show that hybridization may play a key role in species formation in fungi. Because there is very little opportunity for pre-zygotic isolation among yeast species, this mechanism of species formation could be common in the wild and contribute to fungal biodiversity. Our system will prove useful for the study of the different roles of hybridization, chromosomal rearrangements and hybrid adaptation in speciation.

P373 The correlation across populations of mutation effects on fitness. *Ryan Gutenkunst*, Alec Coffman, Aaron Ragsdale, PingHsun Hsieh. University of Arizona, Tucson, AZ.

Divergent selection, in which the same allele has different effects on fitness in different populations, drives environmental speciation. Much is known about patterns of genetic variation near loci with given divergent selection coefficients, but little is known about overall genomic patterns of divergent selection. To fill this gap, we developed a framework for inferring the joint distribution of fitness effects (DFE) between pairs of populations, based on a diffusion approximation to the joint allele frequency spectrum. We applied this framework to African and American populations of Drosophila melanogaster, first estimating demographic history and then the joint DFE. As expected, we found that genome-wide nonsynonymous mutation fitness effects were highly correlated between these two populations. Considering functional subsets of genes, however, revealed striking differences. For example, for muscle development genes the joint DFE has a correlation of roughly zero, whereas for neuronal development genes it is almost one. Divergent selection in these populations is thus operating much more strongly on the musculature than the brain, suggesting that adaptation is primarily physiological rather than behavioral. Future work will apply this general framework to other populations and species, thus quantifying how divergent selection varies with environmental and molecular context.

P374 An Ion-channel Gene Causes Natural Courtship Song Variation in *Drosophila*. *Yun Ding*[1], Augusto Berrocal[1,2], Tomoko Morita[1], Kit Longden[1], David Stern[1]. 1) Janelia Research Campus, HHMI, Ashburn, VA; 2) UC Berkeley, Berkeley, CA.

Animal species display enormous variation for innate behaviors, but little is known about how genomes evolve to generate this diversity. The features of *Drosophila* courtship song are easy to quantify and vary widely within and between species, making song an excellent system for genetic studies. We developed a mapping strategy that combined traditional mapping protocol with high-resolution recombinant mapping using engineered visible markers via CRISPR/Cas9 genome editing. This approach allowed us to map the sine song frequency difference between two wild isolates, *Drosophila simulans 5* and *D. mauritiana 29*, to a 966 bp region within the *slowpoke* locus, which encodes a calcium-activated potassium channel. We confirmed that *slowpoke* is the causal locus using a reciprocal hemizygosity test, and further narrowed down the casual mutation to an intronic insertion of retrotransposon that occurred within *D. simulans* populations. Difference in exon usage was observed around the retrotranspon insertion site. Like many ion-channel genes, *slowpoke* is expressed widely in the nervous system and influences many behaviors. The *slowpoke* mutants sing very little song with disrupted features. However, the naturally evolved *slowpoke* alleles cause significant variation in only one component of courtship song, showing that a highly pleiotropic ion channel gene can evolve to generate a specific new behavior pattern through changes in gene regulation. Currently, we are trying to confirm the retrotranspon insertion as the causal mutation by targeted deletion, and identify the molecular mechanism of how the retrotranspon insertion has fine-tuned the *slowpoke* function. .

P375 Allelic variation of an EXOCYST subunit switches between distinct root system architectures. *W. Busch*, T. Ogura, C. Goeschl, D. Filiault, R. Slovak, S. B. Satbhai, M. Mirea. Gregor Mendel Institute of Molecular Plant Biology, Vienna, AT.

Root system architecture (RSA), the distribution of roots in soil, plays a major role in plant survival. RSA is shaped by processes largely governed by the phytohormone auxin. However, auxin has a central role in numerous other processes and it is unclear which molecular mechanisms allow for the regulation of RSA independently of the numerous other processes that are impacted by auxin. Taking advantage of the remarkable natural genetic variation of *Arabidopsis thaliana*, chemical perturbation of the auxin pathway, and genome wide association mapping, we identify a subunit of a highly conserved molecular complex, the EXOCYST, as a modulator of the auxin pathway. Importantly, the auxin modulatory function of this gene is highly specific for root traits and enables specific regulation of RSA without notably affecting above ground plant traits. At the molecular level, it is acting on the protein distribution of a specific auxin efflux carrier. At the organismal level, allelic variation and genetic perturbation of the EXOCYST subunit lead to alteration of the orientation of root growth and root branching, resulting in a switch from a shallow to a deep root system. Finally, the distribution of alleles of this EXOCYST subunit in natural Arabidopsis populations is highly correlated with precipitation seasonality, suggesting an adaptive role in areas with variable rainfall patterns. We corroborate this idea by showing that overexpression and allelic variation of this EXOCYST subunit affect drought resistance in controlled conditions.

P376 Large scale splicing QTL analysis of cancer genomes. *Kjong-Van Lehmann*[1], Andre Kahles[1], Cyriac Kandoth[1], William Lee[1], Nikolaus Schultz[1], Oliver Stegle[2], Gunnar Rätsch[1]. 1) Memorial Sloan-Kettering Cancer Center; 1275 York avenue; New York City, NY 10065; 2) European Bioinformatics Institute; Hinxton; Cambridge; CB10 1SD; United Kingdom.

The large scale efforts of molecular characterizing thousands of different tumors of The Cancer Genome Atlas (TCGA) network, have enabled new opportunities to undertake quantitative trait analysis at unprecedented sample sizes.To facilitate the joint analysis across various TCGA projects, we have re-aligned and re-analyzed RNA and whole sequencing data of ~4.000 individuals comprising 11 cancer types. RNA-seq data has been processed with SplAdder in order to quantify gene expression and splicing changes, reflecting cancer-specific and tissue-specific

splicing variability. We observe a threefold increase in splicing events compared to GENCODE annotation and estimate an increase of ~20% of splicing complexity in tumor samples. In order to account not only for population structure, which is the most common confounding factor in QTL analysis, but also somatic mutations, recurrence patterns and sample heterogeneity, we employ a mixed model allowing us to model tumor specific genotypic and phenotypic heterogeneity. The large sample size in TCGA allows us to not only find local splicing QTL's but also to detect large effect long range changes, affecting the function of splicing factors. We observe splicing mutations in U2AF1 and SF3B1 caused by somatic alterations. We identify various somatic and germline mutations inducing splicing alterations in many genes and insight into their effects may contribute towards a better understanding of cancer development, progression and treatment.

P377 QTL mapping for hitchhiking behavior in *C. elegans* reveals evolutionary trade-off between dispersal and reproduction. *Daehan Lee*[1], Jun Kim[1], Heeseung Yang[1], Heekyeong Kim[2], Young-ki Paik[2], Leonid Kruglyak[4], Erik Andersen[3], Junho Lee[1]. 1) Seoul National University, Seoul, Korea; 2) Yonsei University, Seoul, Korea; 3) Northwestern University, Evanston, IL; 4) UCLA, Los Angeles, CA.

Caenorhabditis elegans is a species with boom-and-bust life style in fluctuating wild environment. Dauer larvae, which can survive in harsh conditions without food for months, disperse to a new habitat with ample food to resume reproductive growth, either through cruising or hitchhiking. Dauer larvae of *C. elegans* and its close relatives have been discovered in the wild associated with other animals such as isopods or snails. Nictation, a dauer-specific standing and waving behavior, is a hitchhiking behavior which facilitates dauers to attach to these carriers. Here, we show natural variation in nictation behavior among wild isolates of *C. elegans* exhibit a high degree of heritability. By quantitative trait locus (QTL) mapping, we discovered and confirmed a QTL, which we named the *nict-1* locus, involved in nictation variation utilizing molecularly distinguished polymorphisms in two wild isolates. We investigated genetic feature of the *nict-1* locus and analyzed its potential effect on behavioral variation. To assess fitness effect of the *nict-1* QTL, we performed a transmission competition assay using isopods. Our results demonstrate a significant effect of the *nict-1* QTL on the transmission to a new habitat through hitchhiking, as well as an unexpected trade-off effect on reproduction. In summary, we discovered a QTL that exerts a trade-off effect between dispersal and reproduction, two crucial traits for survivor and evolution of the species.

P378 Genetic Analysis of Maize Lines Tolerance to Drought and Soil-Nitrogen Stresses. *Bashir Bello*. Fountain University, Osogbo, Osun State, Nigeria.

The frequency of drought coupled with low-nitrogen (N) soil and increasing cost of N fertilizer that limit maize productivity in West and Central Africa, necessitate breeding cultivars tolerance to both stresses. This study assesses (i) the relationship between maize inbreds performance and their hybrids under optimal, drought and low-N conditions and (ii) the mode of inheritance of nitrogen and drought tolerance stresses in maize. Ten extra-early maize inbred lines were crossed in a half-diallel mating design. The resultant hybrids were evaluated in three environments of managed drought-stress, low-N and optimum-N. Drought tolerant inbreds had high grain yield consistently across all the environments. Several hybrids with at least one tolerant parent generated tolerant hybrids, while crosses between susceptible inbreds produced susceptible hybrids. Additive genetic effects influenced grain yield, ears per plant, anthesis silking interval and leaf senescence under drought, while non-additive gene action conditioned grain yield under low-N. Varietal performance under low-N and drought stresses should lay emphasis on high grain yielding hybrids from parents with suitable general combining ability mean squares for grain yield, ears per plant, leaf senescence and anthesis silking interval under drought stress. Non-additive gene action governing grain yield under low-N and significant general combining ability estimate obtained for grain yield under drought stress signified that development of hybrid is desirable by exploring non-additive genetic control under low-N and drought stresses.

P379 Systems genetics in Maize: A multilevel analysis of Maize response to Ozone. *Lauren M. McIntyre*[1], ALison Morse[1], Alison Gerken[1], Felicia New[1], Linda Young[1], Craig Yendrek[2], Gorka Erice[2], Jessica Wedow[2], Lorena Rios Acosta[2], Crystal Sorghini[2], Chris Montes[2], Ilse Barios-Peres[2], Charles Burroughs[2], Ben Thompson[2], Matt Kendzior[2], John Regan[2], Taylor Pederson[2], Patrick J. Brown[2], Andrew D. B. Leakey[2], Elizabeth A. Ainsworth[2]. 1) University of Florida, Gainesville, FL; 2) University of Illinois at Urbana-Champaign.

In an integrative approach, we use genetic variation as the basis of a systems genetics approach to model phenotypic response to ozone (O_3) exposure in maize. Data from all levels of the system including targeted biochemical assays, measurements of photosynthetic capacity, metabolomics, and RNA-seq are combined to develop a comprehensive picture of Maize response to ozone. Tropospheric ozone is an air pollutant that costs ~$14-26 billion in global crop losses and is projected to worsen in the future. We grew the same genetic material under ambient (40 ppb) and elevated O_3 concentrations (~100 ppb) at the Free Air Concentration Enrichment (FACE) site in Illinois. Little is understood about the physiological processes impaired by elevated O_3 in maize or other C4 species, or whether genetic variation for ozone sensitivity can be exploited in development of future crops. Genetic variation was clearly observed in O_3 sensitivity in the varying responses of ~160 inbred lines, including the nested association mapping population founder lines. From these, 50 lines, including the NAM founders, were retested in 2014 and genetic variation was confirmed. In 2015 10 inbreds and 8 hybrids were extensively tested and these data are the basis of our systems genetics analysis.

P380 Deep sequencing of whole transcriptomes across the Drosophila Genetic Reference Panel. *L. J. Everett*, M. A. Carbone, S. Zhou, G. H. Arya, G. St. Armour, L. Turlapati, R. F. Lyman, T. F. C. Mackay. North Carolina State University, Raleigh, NC.

Genetic variation influences organismal phenotypes in part by altering the transcriptional regulatory architecture that controls mRNA expression levels. However, there remain fundamental questions about the relationship between genetic, transcriptomic, and organismal phenotypic variation, in part because there are few data sets encompassing transcript and phenotype measurements from the same

genotypes. The Drosophila Genetic Reference Panel (DGRP) is a collection of 205 inbred *Drosophila melanogaster* lines harboring natural genetic variation derived from wild-caught flies. Genetic variation was previously mapped across these lines, and multiple research groups have used this collection to map the genetic architecture of various quantitative traits, including alcohol sensitivity, aggression, feeding behavior, and growth control. We have now performed total RNA-seq on adult whole flies across this collection to map genetic variation in the entire transcriptome, including thousands of novel transcripts. We have developed novel analysis pipelines to unify RNA-seq data derived from distinct genomes, and have identified heritable expression patterns in the majority of known genes, as well as transposons and novel transcripts. Additionally, we have found that total RNA-seq libraries from whole flies include signatures of Drosophila microbiomes, and reveal heritable patterns of microbial content across the DGRP. Ultimately this data set will allow the mapping of trait-associated transcripts, eQTLs, and expression correlation networks with unprecedented power and resolution.

P381 Steps toward reproducible research. *Karl W. Broman*. University of Wisconsin-Madison, Madison, WI.

A minimal standard for data analysis and other scientific computations is that they be reproducible: that the code and data are assembled in a way so that another group can re-create all of the results (e.g., the figures in a paper). Adopting a workflow that will make your results reproducible will ultimately make your life easier; if a problem or question arises somewhere down the line, it will be much easier to correct or explain. But organizing analyses so that they are reproducible is not easy. It requires diligence and a considerable investment of time: to learn new computational tools, and to organize and document analyses as you go. Nevertheless, partially reproducible is better than not at all reproducible. Just try to make your next paper or project better organized than the last. There are many paths toward reproducible research, and you shouldn't try to change all aspects of your current practices all at once. Identify one weakness, adopt an improved approach, refine that a bit, and then move on to the next thing. I'll offer some suggestions for the initial steps to take towards making your work reproducible.

P383 Domestic pigeon's checkered past: a link between color patterning, introgression, and hereditary blindness. *A. I. Vickrey*, Z. Kronenberg, R. Bruders, E. J. Osborne, M. Yandell, M. Shapiro. University of Utah, Salt Lake City, Utah.

Animals have evolved a vast array of colors and color patterns in response to natural, sexual, and artificial selection. Domestic rock pigeons (*Columba livia*) are a stunning example of this diversity because different individuals within the same species vary tremendously in color and color pattern. Classical genetics suggest that four alternative alleles (T-check, Checker, Bar, Barless in decreasing order of dominance and melanism) at a single locus determine wing color pattern. Although the Bar pattern is thought to be the ancestral phenotype, birds with the Checker and T-check patterns are more numerous in urban environments, possibly due to enhanced fitness. In this study we investigate the genetic basis of wing color pattern variation. We performed whole-genome comparisons between Bar and Checker birds to identify a candidate region containing just a few genes that was highly differentiated between the two phenotypes. Surprisingly, cross-species sequence comparisons suggest that a haplotype in this region that is shared by all Checker birds was introgressed into the rock pigeon from a different species, providing a striking example of cross-species transmission of a potentially adaptive phenotype. One gene in the candidate region shows expression differences among Bar, Checker, and T-check alleles in regenerating feathers indicating a cis-regulatory change at this locus. Lastly, we find that Barless birds, which have an increased incidence of vision defects, are homozygous for a nonsense mutation in a gene that is associated with blindness in humans. Remarkably, the same mutation we find in pigeons is also observed in two human families with hereditary blindness. This study highlights unexpected molecular links between color pattern, adaptive introgression, and vision defects in a classical model organism.

P384 Whole genome sequencing studies of speciation and selection in the Lake Malawi cichlid radiation. *R. Durbin*[1], M. Malinsky[1,2], H. Svardal[1], A. Tyers[3], M. Genner[4], E. Miska[1,2], G. Turner[3]. 1) Wellcome Trust Sanger Institute, Hinxton, UK; 2) Gurdon Institute, Cambridge Univ., UK; 3) Bangor Univ., UK; 4) Bristol Univ., UK.

The thousands of haplochromine cichlid fish species found in the African rift valley great lakes and surrounding rivers constitute perhaps the most dramatic vertebrate evolutionary radiation. Lake Malawi contains over 500 morphologically and ecologically diverse species that have separated within the last million years or so. In this presentation we will relate recently published results on the sympatric separation of two *A. calliptera* ecomorphs in Lake Massoko, a small crater just north of Lake Malawi (Malinsky et al, Science, 2015), to results from unpublished whole genome sequences of over 150 fish from over 85 species in the main Lake Malawi.

In the Lake Malawi sequences we observe a large amount of shared variation segregating across species, with pairwise Fst varying from 5% to 65% (diversity within species 0.05-0.1%, divergence between species 0.1-0.3%). The average phylogeny shows numerous differences to the standard taxonomy, with multiple instances of repeated phenotypic specialization across the phylogeny. As in Massoko, we see evidence of selection in the visual system, and we are testing loci selected in Lake Massoko for signs of independent repeated selection within Lake Malawi. Because of the shared variation the gene phylogeny varies across the genome. In part this is expected due to incomplete lineage sorting, but using D statistics we also see evidence for gene flow between separate branches of the species phylogeny, and are looking for evidence of selection acting on this gene flow.

We recently collected 1500 more samples from ~250 species to enable more detailed studies into speciation and selection. Finally, we are making all our sequences openly available, to enable others already working on the evolution of Malawi cichlids to also study the genetic sources of phenotypic diversity in this rich system, and are also collaborating with the Genome10K initiative to establish reference genome sequences more broadly to cover vertebrate diversity.

P385 How much do chromosomal inversions prevent gene conversion and interspecies gene flow? *Katharine Korunes*. Duke University, Durham, NC.

Many distinct species continually hybridize, and the persistence of these species is attributed in part to recombination barriers such as chromosomal inversions. Chromosomal inversions are proposed to act as barriers to recombination in inversion heterozygotes, but the strength of these barriers remains poorly understood. While single crossover products are prevented within inversions, non-crossover gene conversion can occur in and around chromosomal inversions, potentially even at high rates, rendering inversions less effective at preventing gene flow. There are extremely limited empirical estimates of non-crossover gene conversion rates with respect to chromosomal inversions, so despite the prevailing thinking, inversions may be quite ineffective at keeping hybridizing species distinct. To test the efficacy of chromosomal inversions at maintaining LD in hybrids, I am utilizing the naturally-hybridizing species pair *Drosophila pseudoobscura* and *D. persimilis.* Using whole-genome sequence data from experimental crosses, I detect gene conversion rates within inverted regions of species hybrids that are at least as high as rates based on within-species LD data. With these data, we can assess rates of gene flux and better understand the conditions under which chromosomal inversions reduce interspecies gene flow. Given such high rates of gene conversion in hybrids but high sequence differentiation between species, other features of this system must be maintaining the distinction of these species besides the recombination barrier provided by chromosomal inversions.

P386 Convergent evolution of regulatory regions in flightless birds. *Tim Sackton*, Phil Grayson, Alison Cloutier, Michele Clamp, Scott Edwards. Harvard Univ, Cambridge, MA.

A fundamental question in evolutionary biology is the extent to which convergent changes in phenotype are driven by convergent changes at the sequence level. Recent phylogenetic work strongly supports multiple independent losses of flight in the ratites (ostriches, rheas, kiwis, cassowaries, and emu), providing a compelling system to understand the degree of genomic convergence associated with flight loss. We have sequenced 10 new high-quality palaeognath genomes (including 7 flightless ratites and 3 volant tinamous), and aligned these with 32 existing sequenced genomes of reptiles and birds to identify 284,000 conserved non-exonic elements (CNEEs) greater than 50 bp in length. Of these, 15,000 are specifically accelerated and/or lost in at least one ratite lineage. We show that a disproportionate number of these elements are accelerated in multiple independent ratite lineages, suggesting that convergent changes in putative regulatory sequences may be associated with independent losses of flight. Genes nearest to convergently accelerated CNEEs are enriched for developmental functions, and include several candidate genes with roles in limb development. Limb development is particularly relevant to loss of flight as forelimbs (wings) are reduced in size or lost in all ratites. Ongoing experimental work aims to determine whether genes close to convergently accelerated CNEEs are differentially expressed during the development of volant (chicken) and flightless (emu) species, and ultimately whether the sequence changes occurring in convergently accelerated CNEEs are associated with detectable changes in regulatory function. Overall, our results suggest that convergent evolution of non-coding regulatory sequence is an important driver of convergent phenotypic evolution in flightless ratites.

P387 Genomic imprinting and speciation in mammals. *J. Good*, T. Brekke. University of Montana, Missoula, MT.

Extreme hybrid growth is common in mammals, indicating that disruption of early development may play an important role in mammalian speciation. Hybrid growth effects often follow a parent-of-origin dependent pattern where reciprocal hybrids differ in size and are either larger or smaller than the parental species. Disruption of genomic imprinting, the parent-specific epigenetic silencing (imprinting) of one allele, has been linked to growth effects underlying diverse human diseases and has been hypothesized to be the predominant cause of abnormal hybrid growth. This hypothesis predicts that loss of imprinting in hybrid placentas should result in parent-of-origin dosage imbalances between paternally expressed growth factors and maternally expressed repressors. We have combined transcriptomic and quantitative genetic experiments to dissect the regulatory underpinnings of extreme parent-of-origin hybrid overgrowth between two species of dwarf hamsters. First, we tested for disrupted placental gene expression in overgrown hybrid placentas. We observed extensive transgressive expression of growth-related genes and bi-allelic expression of several paternally imprinted genes generally associated with growth repression. Surprisingly, the apparent disruption of paternal imprinting was also associated with severely reduced expression levels. These patterns are contrary to the predictions of the loss of imprinting model and suggest that misexpression of dosage sensitive genes in hybrids is caused by other mechanisms in this system. Next, we performed a backcross and identified the X chromosome as the major maternal factor explaining hybrid placental overgrowth. Expression analyses on large and normal backcross placentas revealed substantial autosomal misexpression but normal imprinted expression of the X chromosome. These results indicate that X-linked genetic incompatibilities are not caused by chromosome-wide de-regulation but may be involved in epistatic interactions that lead to the disruption of autosomal imprinting. Collectively, our results support a central role for both disrupted epigenetic processes and the X chromosome in the evolution of extreme hybrid growth in mammals.

P388 Cryptic genetic variation and the evolution of complex traits. *A. B. Paaby*. Georgia Institute of Technology, Atlanta, GA.

Conditionally functional mutations are an important class of natural genetic variation, yet little is known about their prevalence in natural populations or how they mediate adaptive trajectories. In this talk I describe a vast reserve of cryptic genetic variation, alleles that are normally silent but which affect phenotype when the function of other genes is perturbed, in the gene networks of C. elegans embryogenesis. I find evidence that cryptic-effect loci are ubiquitous and segregate at intermediate frequencies in the wild. The cryptic alleles demonstrate low developmental pleiotropy, in that specific, rather than general, perturbations are required to reveal them. My findings underscore the importance of genetic background in characterizing gene function and provide a model for the expression of conditionally functional effects that may be fundamental in mechanisms of trait evolution.

P389 Dissecting the large X-effect in Drosophila speciation: high resolution mapping and the identification of hybrid male sterility genes. *C. Meiklejohn*[1], E. Landeen[2], K. Gordon[3], S. Biel[3], D. Stern[4], D. Presgraves[2]. 1) University of Nebraska-Lincoln, Lincoln, NE; 2) University of Rochester, Rochester NY; 3) Indiana University, Bloomington, IN; 4) HHMI Janelia Research Campus, Ashburn, VA.

In animals with heteromorphic sex chromosomes, the first interspecific genetic incompatibilities to accumulate cause sterility in the heterogametic (XY) sex and are disproportionately X-linked. Why the X chromosome has unique roles in the rapid evolution of gametogenesis and speciation is unclear. To determine the evolutionary and molecular genetic basis of the "large X-effect" in speciation, we have generated an ultra high-resolution genetic map of X-linked hybrid male sterility (HMS) factors between two sister species, *Drosophila mauritiana* and *D. simulans,* by introgressing doubly-marked segments of the *D. mauritiana* X chromosome into a *D. simulans* genome. This map comprises over 500 overlapping introgressed segments ranging in size from 2 Mb to 100 kb that were genotyped at thousands of markers by light-coverage resequencing. Our genetic mapping data, coupled with data on introgression between these species in nature, provide insights into the consequences of incompatibilities for gene flow. Furthermore, a recent selective sweep in *D. mauritiana* plausibly associated with a meiotic drive element appears to have prevented the accumulation of linked HMS factors in this region of the X chromosome. We have further refined three regions to a dozen candidate HMS genes, and in one of these regions, we have identified and transgenically validated a new HMS gene. Identification of multiple X-linked HMS genes will allow broad generalizations on the functions of these genes within species, the etiology of HMS, the evolutionary forces involved in interspecific divergence, and the overall molecular basis of the large X-effect.

P390 The naturally variable ELF3 polyglutamine is the hub of an epistatic network in *Arabidopsis thaliana*. *Maximilian Press*, Christine Queitsch. University of Washington, Seattle, WA.

Short tandem repeats are hypervariable genetic elements occurring frequently in coding regions. Their fast mutation rate has been recognized as a potent source of genetic variation contributing to adaptive evolution and the heritability of human disease. We recently proposed that such repeats are likely to mediate epistasis, by supplying compensatory mutations in certain genetic backgrounds. We have previously described one such case, in the *A. thaliana* gene *ELF3*, of a short tandem repeat that encodes a highly variable polyglutamine. In a twofold approach, we 1) dissected the genetic architecture of this incompatibility between two *A. thaliana* ecotypes, and 2) used a yeast two-hybrid strategy to identify proteins whose physical interactions with ELF3 were modulated by polyglutamine status. Using these two orthogonal approaches, we identify specific genetic and physical mechanisms by which the *ELF3* repeat may mediate the observed genetic incompatibilities. Our work elucidates a variety of mechanisms by which repeat variation, which is generally underascertained in population-scale sequencing, can control phenotypic variation. Furthermore, our work suggests that such highly variable loci contribute disproportionately to the epistatic component of heritability. We also show preliminary data from new sequencing technologies identifying more such highly variable repeats.

P391 Functional compensation and dependency between duplicated genes in protein interaction networks. *C. R. Landry*, G. Diss, I. Gagnon-Arsenault, H. Vignaud, C. Berger, A. M. Dion-Coté. Université Laval, Québec, Canada.

According to evolutionary models of gene duplication, paralogous genes are functionally identical after duplication and slowly diverge by partitioning ancestral functions and/or acquiring new ones until becoming functionally independent. Paralogs may influence each other's evolutionary fate during this period. First, the functional redundancy of the two duplicates may affect the fitness consequences of mutations in one member of a pair, for instance by masking deleterious mutations through functional compensation. Second, the function of the two duplicates may be functionally linked by mechanisms such as cross-regulation or physical interaction between gene products. The two paralogs could thus evolve as a single functional unit. Here we study this interdependency in the yeast protein interaction network by examining whether duplicated genes affect each other's protein-protein interactions when deleted. We tested 56 pairs of duplicated genes in the yeast *Saccharomyces cerevisiae* and found that for a large fraction of them, deleting one duplicate leads to gains of interaction by the other, following patterns that are consistent with a mechanism of functional compensation. We also found an unexpectedly large proportion of pairs that exhibit functional dependency, i.e. partial or complete loss of protein-protein interactions of the remaining paralog after the deletion of its sister copy. Our results provide a molecular mechanism for functional compensation between paralogs, show that functional dependency is widespread among duplicate pairs and suggest that paralogs often do not diverge independently but constrain each other's evolutionary fate.

P392 High-throughput measurements of the evolutionary consequences of epistasis. *J. I. Rojas Echenique*[1], A. N. Nguyen Ba[1], S. Kryazhimskiy[2], M. M. Desai[1]. 1) Harvard University, Cambridge, MA; 2) UCSD, La Jolla, CA.

Epistatic interactions underlie foundational problems in evolutionary biology: the role of history and chance in determining the outcomes of evolution, the relative difficulties of evolving different complex adaptations, and the evolution of sex and recombination. To characterize the general patterns of epistasis produced by adaptation, we evolved 20 replicate populations of 36 different yeast gene deletion mutants and measured the epistasis between the initial gene deletions and the mutations acquired in the course of adaptation. We found that rates of adaptation were genotype dependent and sought to explain this result in terms of the measured epistatic effects.

P393 Beyond candidate genes: Mapping monogenic trait modifiers using informative recombinant progeny in yeast. *A. Sirr*, A. Scott, G. Cromie, E. Jeffery, C. Ludlow, T. Morgan, A. Dudley. Pacific Northwest Diabetes Research Inst, Seattle, WA.

Clinically relevant features of monogenic diseases, including severity of symptoms and age of onset, can vary widely in response to environmental differences as well as to the presence of genetic modifiers affecting the trait's penetrance and expressivity. While a better understanding of modifier loci could lead to treatments for Mendelian diseases, the rarity of individuals harboring both a disease causing allele

and a modifying genotype hinders their study in human populations. Our interest in studying the effect of modifiers on monogenic traits has led us to investigate a dimorphic trait of *Saccharomyces cerevisiae* when grown on a colorimetric medium used in clinical identification of fungal pathogens. While the majority of natural isolates of *S. cerevisiae* develop a distinct purple color on this medium, a small number remain white, demonstrating that this trait is dimorphic in the population. To characterize the nature of this variation further, we preformed QTL analysis on a large number of recombinant progeny produced by a cross between white and purple parental strains. Our results identified a major QTL peak over a region that includes the tandemly arrayed paralogs *PHO3* and *PHO5*, suggesting the colorimetric assay is an indicator of acid phosphatase activity. Sanger sequencing of these loci in 28 white strains in our natural variant collection revealed most strains harbored a gene fusion of the two phosphatase genes that deleted the constitutively expressed *PHO3* promoter region. Gradations in color among the progeny of the cross suggested additional genes, unlinked to the *PHO3- PHO5* locus, could modify the acid phosphatase activity. We used time-lapse photography to quantitatively measure the growth and development of purple color of each individual colony over time. By conditioning on the major QTL allele, we identified additional secondary QTL peaks that differed between the two groups and observed a QTL peak with a LOD score that declined over the time course of the experiment. In order to identify modifiers of acid phosphatase activity, we are currently applying a novel high throughput method to isolate informative recombinant progeny for targeted genotyping.

P394 Characterizing patterns of epistasis in yeast experimental evolution. *Gregory I. Lang*[1], Sean W. Buskirk[1], Ryan Emily Peace[2]. 1) Department of Biological Sciences, Lehigh University, Bethlehem, PA 18015; 2) Bioengineering Program, Lehigh University, Bethlehem, PA 18015.

Understanding how genes interact is a central challenge in biology. Non-additive genetic (epistatic) interactions are crucial in constraining evolutionary trajectories and underlie many complex traits. Yet high-throughput methods for uncovering epistatic interactions are lacking. The current “gold standard” approach for characterizing epistasis is to engineer all possible combinations of evolved mutations and to measure the fitness of each genotype. Though powerful, this strategy is not practical for populations that contain more than a few mutations. To overcome this limitation we developed a new high-throughput method for assaying fitness and epistasis in genetic crosses and applied this method to twelve populations from a previously published yeast evolution experiment.

By crossing each evolved clone with its ancestor, we generated large pools of recombinant progeny containing random combinations of evolved mutations. For each of the twelve crosses we determined the distribution of fitness among 192 randomly selected recombinant individuals. Next, we determined the background-averaged fitness effect for all 111 mutations across our twelve evolved populations by propagating the recombinant pools and quantifying the change in frequency of each mutation over time. We developed a theoretical framework that combines these two data sets to reveal the patterns of epistasis among the mutations in each population.

Our analysis shows that most interactions between evolved mutations follow the model of “global diminishing returns” epistasis. This method also succeeded in identifying several new examples of idiosyncratic epistasis. We are beginning to explore the biological basis underlying these interactions. This is the first step towards understanding how epistatic interactions arise in the context of evolution and how epistasis influences the dynamics of adaptation.

P395 Genetic Interactions Suppress Extreme Bone and Weight Phenotypes in a Mouse Intercross. *Gregory W. Carter*, Anna L. Tyler, Leah Rae Donahue, Gary A. Churchill. The Jackson Laboratory, Bar Harbor, ME.

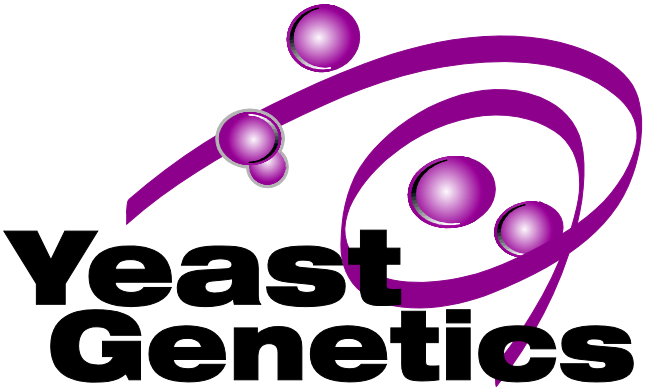
Bone density and other body composition phenotypes are complex traits with many contributing genetic factors, both shared and distinct. Genetic interactions are often suspected to contribute to the genetic architecture of such phenotypes, but understanding their role and extent is commonly limited by sample size. To reduce this limitation, we created a large F2 intercross of over 2000 B6.lit/lit x C3H.lit/lit mice to investigate interactions influencing femoral density, femoral circumference, body fat, and body weight. We used a combined analysis of pleiotropy and epistasis to infer how multiple quantitative trait loci (QTL), sex, and circulating growth factor IGF1 interact to influence all traits simultaneously. A large connected network with dozens of directed genetic interactions among multiple distinct QTL was obtained and analyzed, from which we obtained insights into the genetic architecture of this intercross populations. Recurrent patterns of QTL interactions with sex and circulating IGF1 suggested regulatory and compensatory roles for candidate genes. The QTL network was dominated by genetic interactions that reduced the occurrence of extreme phenotypes when the two interacting loci shared a common parental genotype. Rather than widespread genetic buffering, in which extreme phenotypes arise from strong synergistic interactions between QTL pairs, we found a genetic architecture characterized by (1) weak interactions that adjusted additive variance, and (2) genetic redundancy. This first class of phenotype-stabilizing interactions has effects that are close to additive and are thus difficult to detect except in very large sample sizes. We interpret these findings as a genetic mechanism of homeostasis for each inbred parental strain that is disrupted by allelic assortment via intercrossing. Our results suggest that while epistasis is often weak and unlikely to account for a large proportion of heritable variance, even small-effect genetic interactions can facilitate hypotheses of underlying biology in well-powered studies.

P396 Can epistasis or GxE be predictable? Lessons from mitonuclear interactions in Drosophila. *D. M. Rand*, J. A. Mossman, L. A. Biancani, C.-T. Zhu. Brown Univ, Providence, RI.

Epistasis and genotype by environment interactions (GxE) are likely sources of the missing heritability for complex traits that have emerged from genome wide association studies (GWAS). In an effort to understand the role of gene by gene (GxG) and GxE interactions in the mapping of genotypes in to phenotypes, we have built a panel of 72 mitonuclear genotypes constructed from all pairwise combinations of 6 mtDNAs of D. melanogaster and D. simulans and 12 of the Drosophila Genetic Reference Panel (DGRP) strains. One prediction is that mitonuclear epistasis will scale with mtDNA sequence divergence. Another is that the importance of epistasis will vary across environments. We have quantified

development time and other fitness traits on different isocaloric diets of yeast and sugar to assess the individual and joint contributions of mitochondrial, nuclear and dietary environment to these phenotypes. While certain DGRP lines support the mtDNA divergence prediction, the majority of nuclear backgrounds show no significant effect of mtDNA divergence on development time. However, a number of DGRP backgrounds show striking reversals of phenotype across different mtDNAs. The role of mitonuclear epistasis is most pronounced in the low protein diet with the slowest development. Notably, those DGRP backgrounds that demonstrate the most dramatic epistatic interactions with mtDNAs are the most responsive to dietary modification of development time. These observations raise the hypothesis that GxG and GxE interactions are not distinct phenomena but are related. This notion becomes intuitive if either epistatic partner lies in a pathway where an abiotic environment alters the genetic or cellular environment that governs the expression either gene. This joint mitochondrial and nuclear genomic approach manipulates a number of metabolic processes that can add predictability to GxG and GxE effects underlying the putative missing heritability for complex traits.

YEAST
GENETICS MEETING



Plenary and Platform Session Abstracts

Yeast Genetics Meeting

SCHEDULE AT-A-GLANCE

Wednesday, July 13		
2:00pm-9:30pm	Speaker Ready Room Open	Hall of Cities - Anaheim
7:00pm-9:00pm	Scientific Session: The Dynamic Genome Winge-Lindegren Address presented by Rodney Rothstein	Crystal Ballroom G2
9:00pm-11:00pm	Opening Mixer with Exhibits	Cypress Ballroom
Thursday, July 14		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities -Anaheim
7:45am-10:00am	Genetics and Determinants of Health Joint Plenary Session	Palms Ballroom
8:00am-4:00pm	Exhibits Open	Cypress Ballroom
9:00am-8:00pm	Demo Room: MOD (FlyBase, MGI, SGD, WormBase, Zfin) Demo Room Open	Palms Ballroom Canary 3-4
10:30am-12:30pm	Scientific Session: Post-Transcriptional Gene Regulation	Crystal Ballroom G2
12:30pm-1:30pm	Mentoring Roundtables #1	North Tower - Harbor Beach
12:30pm-1:30pm	Speaking Up for Genetics and Model Organism Research	Crystal Ballroom H
1:30pm-3:30pm	Poster Presentations 1:30pm-2:30pm: Even-numbered poster 2:30pm-3:30pm: Odd-numbered posters	Cypress Ballroom
1:30pm-3:30pm	GeneticsCareers Center and Job Fair	Cypress Ballroom 1C
4:00pm-6:00pm	Scientific Session: Epigenetics and Transcriptional Regulation	Crystal Ballroom G2
4:00pm-6:00pm	Plenary Session and Workshop for Undergraduate Researchers	North Tower - Sawgrass
7:45pm-9:45pm	Scientific Session: Tackling Human Disease Using Yeast Ira Herskowitz Award presented to Lars Steinmetz	Crystal Ballroom G2
10:00pm-11:30pm	*Science Cafe Event	Palms Ballroom Sabal
Friday, July 15		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities - Anaheim
8:00am-9:30am	Scientific Session: Division and Development	Crystal Ballroom G2
8:00am-4:30pm	Exhibits Open	Cypress Ballroom

Y463 Winge-Lindegren Address. *Rodney Rothstein*. Columbia Univ Med Ctr, New York, NY.
no abstract submitted

Y464 Using Experimental Evolution To Engineer A Low Flocculation Yeast Strain. *Elyse A. Hope*, Clara J. Amorosi, Aaron W. Miller, Kolena Dang, Caiti Smukowski Heil, Maitreya J. Dunham, 2015 CSHL Yeast Genetics and Genomics Course. University of Washington, Seattle, WA.

Yeast flocculation is a community-building cell aggregation trait that is a key contributor to brewing but a nuisance in other industrial processes, the laboratory, and clinical settings. This dichotomy demonstrates the importance of understanding and manipulating the genetic determinants of cell aggregation to achieve phenotypically desirable outcomes on both ends of the spectrum. Experimental evolution in the laboratory provides a unique testing ground for understanding the breadth of genetic mechanisms *Saccharomyces cerevisiae* uses to achieve cell aggregation. The popular lab strain S288C does not aggregate due to a nonsense mutation in the gene encoding transcription factor Flo8, which regulates flocculation. Despite this mutation, these strains evolve the ability to aggregate during 35% of our continuous culture evolution experiments. These evolved strains present an opportunity to examine the adaptive routes that lead to cell aggregation and whether one or many routes are favored.

We have analyzed 23 evolved clones using a combination of whole genome sequencing, quantitative phenotyping, and Bulk Segregant Analysis (BSA), a pooling and sequencing approach. All of the clones exhibit a significantly stronger aggregation phenotype than the ancestor, and none of the strains reverted the point mutation in *FLO8*. We recovered two loss of function mutations in *ACE2*, which has been previously shown in the literature to cause mother-daughter separation defects. BSA revealed causal mutations in *TUP1*, a known regulator of flocculation gene *FLO1*, and *ROX3*, which has not been previously connected to flocculation in the literature. Most interestingly, we discovered a common mutation among 13 of the evolved clones: a Ty1 transposable element insertion in the promoter region of the flocculation gene *FLO1*. Discovering this common adaptive mechanism indicated that rather than many equally favored adaptive routes, changing the regulation of *FLO1* is the preferred route for evolving flocculation. We engineered a *flo1* knockout strain and evolved it comparatively against a wild-type lab strain, with 32 replicates of each. We determined that this single gene deletion reduced flocculation occurrences from 25% to 3% over 250 generations. Deleting *FLO1* had no effect on the evolution of unrelated phenotypes (separation defects and wall sticking), demonstrating the efficacy of this evolve-sequence-design approach for engineering targeted phenotypic outcomes.

Y465 Ploidy tug-of-war: evolutionary and genetic environments influence the rate of ploidy drive in a human fungal pathogen. *M. A. Hickman*[1], A. C. Gerstein[2], H. Kim[2], J. Berman[2,3]. 1) Emory Univ, Atlanta, GA; 2) Univ of Minnesota, Minneapolis, MN; 3) Tel Aviv Univ, Tel Aviv, Isreal.

Ploidy contributes to the evolutionary dynamics and to the cellular physiology of organisms. Significant variation for ploidy is seen throughout the tree of life yet the factors that determine why one ploidy level is selected over another remain poorly understood. Asexual fungal microbes are a unique system to study ploidy dynamics as they are incredibly tolerant to karyotypic variation in both the number of chromosome sets as well as single (or few) chromosomes deviations from euploidy. Such variation can be rapidly selected for or against depending on the environment, yet evolution experiments have revealed a propensity to return to the historical baseline ploidy level under a variety of environmental conditions, a phenomenon that we term here as 'ploidy drive'. To assess the interplay between environmental pressure and strain genotype on ploidy drive, we evolved ten strains of the human fungal pathogen *Candida albicans* of varying initial ploidy under four environmental conditions. We found selection for increased genome sizes under nitrogen limitation and in a complete medium yet selection for smaller genome sizes was observed under phosphorus limitation and in minimal medium. Furthermore, genetic background had a significant role in ploidy drive dynamics, as some genotypes were markedly less stable than others. Combined, this work demonstrates a role for selection at both the environmental and genotypic level in the rate of ploidy drive.

Y466 Mechanism of non-genetic heterogeneity in yeast growth rate and stress resistance. *Shuang Li*, Mark Siegal. New York University, New York, NY.

Despite its genetic homogeneity, a clonal population can display marked heterogeneity in various aspects, such as growth rate and stress resistance. Such heterogeneity may have important clinical implications in tumor biology and microbial pathogenesis. As a model eukaryote and opportunistic pathogen, the budding yeast *Saccharomyces cerevisiae* provides an excellent model for studying non-genetic heterogeneity. Isogenic yeast cells, cultivated under benign conditions, divide at different rates. Slow-growing cells disproportionately survive acute heat shock and have high expression of a stress-protective factor, TSL1. Knocking out TSL1 significantly reduces survival of acute heat shock but has negligible effect on growth. The molecular mechanisms that generate non-genetic variation in yeast-cell growth rate and stress resistance have not been characterized. We identified the paralogous transcription factors MSN2 and MSN4, and the upstream protein kinase A (PKA) pathway, as candidate regulators of this heterogeneity. MSN2 and MSN4 regulate the general stress response. PKA regulates their phosphorylation status, which determines their nuclear import and export rates. Although there have been extensive studies on the function and subcellular localization dynamics of MSN2 and MSN4 under stress, the significance of MSN2 and MSN4 under benign conditions has rarely been explored. We use high-throughput time-lapse microscopy to measure growth and gene expression in microcolonies founded by individual cells. The negative correlation between single-cell growth rate and TSL1 expression level is abolished in msn2 mutants but not msn4 mutants, which suggests only MSN2 is necessary in regulating heterogeneity in TSL1 expression and stress resistance. The population growth-rate distributions of *msn2*, *msn4* and *msn2 msn4* double mutants all show similar, significant reduction of slow growers compared with wildtype. These results suggest that MSN2 and MSN4 are each necessary in regulating slow growers. The proportion of slow growers also decreases significantly in mutants lacking subunits of the PKA complex, TPK1 or TPK2, and the decrease is even stronger than in *msn2* mutants. Therefore, PKA regulates

slow growers, but not solely through MSN2 and MSN4. Monitoring of MSN2 intracellular localization reveals that heterogeneity likely derives in part from its nuclear dwell time: MSN2 enters the nucleus more frequently and stays there longer in slow-growing cells, presumably leading to differential expression of target genes and thereby different growth and stress-resistance states.

Y467 The concerted function of the Shu complex and the Rad51 paralogs in Rad51 presynaptic assembly. *K. A. Bernstein*[1], T. McClendon[1], M. Sullivan[1], W. Gaines[2], S. K. Godin[1], P. Sung[2], J. Yanowitz[1], K. A. Bernstein[1]. 1) Univ Pittsburgh School of Medicine, Pittsburgh, PA; 2) Yale University School of Medicine, New Haven, CT.

Double-strand breaks (DSBs) are one of the most cytotoxic forms of DNA damage. Defects in DSB repair are associated with cancer predisposition, as well as, several heritable diseases including Fanconi anemia. Our work has centered around Rad51 paralog function during DSB repair. Importantly, mutations in the human Rad51 paralogs are found in tumors and also lead to Fanconi anemia. Due to the embryonic lethality of the mouse knockout models and the low abundance and insolubility of the human proteins, there is very limited understanding as to how the Rad51 paralogs function to maintain genomic integrity. To circumvent these obstacles, we are studying the role of a unique Rad51 paralog-containing complex, called the Shu complex, in the budding yeast *S. cerevisiae* and the nematode *C. elegans*. Although the Shu complex was discovered 10 years ago and is critical for DSB repair, its molecular function has remained elusive. We discovered that the yeast Shu complex is highly conserved from archaea through humans. Furthermore, we have identified direct physical interacting partners of the yeast and worm Shu complex and to show that these interactions are necessary and sufficient for the biological efficacy of the Shu complex during DSB repair. We define a molecular role for the yeast and worm Shu complexes in Rad51 presynaptic filament assembly, and thus for the first time gained insight into its mechanistic function. Our work has important implications for how the Rad51 paralogs and the human Shu complex function to prevent tumorigenesis and Fanconi anemia.

Y468 Genome-wide detection of genomic fluctuations in *Saccharomyces cerevisiae*. *K. Palacios Flores*, M. Boege, A. Castillo, J. Garcia, L. Gomez, C. Uribe, G. Davila. Laboratorio Internacional de Investigacion sobre el Genoma Humano, UNAM, Queretaro, Queretaro, MX.

The aim of our study is to define, at the nucleotide level, the most dynamic sites in the *S. cerevisiae* genome. To this end, we designed an experimental strategy that could naturally result in population structure remodelling of a *S. cerevisiae* primary culture. A liquid culture of the S288c strain was prepared and used to plate single cells, which were then allowed to form two-day colonies. Whole genome sequencing was performed for the primary culture and for 91 colonies. To detect genome dynamics in an unbiased manner, we devised a bioinformatics approach that culminates in the formulation of a general signature of variation for sequenced genomes. This signature can be used to scan genomes in the search for different types of variation including SNVs, microindels, deletions, insertions, and amplifications. Herein, we focused on the detection of amplification sites along the genome. Amplifications represent a particularly attractive study case because they provide a physical platform for further dynamic behaviour. We found 187 amplifiable sites located all along the genome, with no obvious preference for any chromosome or chromosomal region. Different sites vary widely in the proportion of cell populations that fall above a 2 fold amplification threshold. The latter suggests the existence of a characteristic dynamic spectrum for each site. For those cases where most of the cell populations pass the amplification threshold, the primary culture does so as well. This suggests that the amplification level of the single cell founders of these populations could have an important role in driving the amplification level of the growing colonies. By comparing the amplification level of each site across cell populations, it became evident that the population structure of the primary culture was remodelled both towards higher and lower levels of amplification, generating a gradation of possibilities. This suggests the action of a stochastic and reversible dynamic process at these sites. Finally, upon computing the dynamic range of amplification levels for each site, we observed up to 4 fold differences. This is considerable when taking into account that derived cell populations were grown under identical conditions and under no obvious selective pressure. We propose the concept of genomic fluctuation: the result of a highly dynamic and reversible process capable of generating genomic differentiation between populations derived from a common and recent origin within a single species. We expect this concept will contribute to the general understanding of the genome as a dynamic entity.

Y469 A cradle-to-grave analysis of *cis*-regulatory variation in yeast. *J. M. Andrie*, G. E. Merrihew, J. Madeoy, D. S. Gordon, D. Akey, E. E. Eichler, D. R. Morris, J. Wakefield, M. MacCoss, J. M. Akey. University of Washington, Seattle, WA.

Cis-regulatory variation is an important source of phenotypic variation within populations and a major target of adaptive divergence between species. However, the molecular processes that are influenced by *cis*-regulatory variation remain poorly understood. To this end, we crossed two genetically diverse wild-derived strains of *Saccharomyces cerevisiae* and studied allele-specific differences in eight molecular phenotypes, including chromatin structure, rates of RNA transcription, decay and translation, RNA secondary structure, binding of proteins to RNA, steady-state protein abundance, and protein decay rates. Furthermore, we performed high-coverage sequencing of both the genome (using PacBio) and the transcriptome, and *de novo* assembled each parental strain to mitigate read mapping biases and ensure accurate estimates of allele-specific phenotypes. We show that *cis*-regulatory variation has pervasive effects on high-dimensional molecular phenotypes, and pleiotropy and buffering are predominant features in the architectural landscape of *cis*-regulatory mutations. Our comprehensive data also provides novel mechanistic insights into *cis*-regulatory variation. We anticipate that our data will be of considerable general interest, and a powerful resource to test hypotheses about the evolution of *cis*-regulatory variation.

Y470 Msn2 regulates cellular response and growth to stress through modulation of its localization and DNA binding. *V. Bharatula*[1], R. Chereji[2], J. Broach[1]. 1) Penn State College of Medicine, Hershey, PA; 2) National Institute of Child Health and Development, Bethesda, MD.

Yeast perceive and respond to changes in their external environment by rapidly modulating its transcriptional program. A core set of genes are upregulated and repressed under several stresses examined. These genes are under the transcriptional control of the stress responsive factor Msn2. Single cell microscopy studies revealed that Msn2 re-localizes from the cytoplasm to the nucleus when cells are stressed. This change in localization is dynamic, which is observed by the presence of short-lived random bursts of Msn2 nuclear occupancy. We observed that Msn2 localization was uniquely modulated for different stresses. We investigated the consequence of this dynamic behavior of Msn2 on transcription of genes using microarrays. Ectopic expression of transient and prolonged nuclear Msn2 forms led to differential gene expression kinetics. Some genes were readily induced *i.e* fast responding and others required a constant nuclear presence of Msn2. This suggests that by modulating transcription factor dynamics yeast can selectively regulate gene expression depending on the stressor. Whole genome chromatin immunoprecipitation and nucleosome positioning studies post nutrient downshift and oxidative stress corroborated our findings and we observed Msn2 binding to promoters of common stress regulated genes as well as genes pertaining to the stressor. Isogenic cells also responded to stress distinctly, with some cells showing prolonged nuclear accumulation of Msn2 and others a more transient phenotype. Overexpression of constitutively nuclear phospho-mutant Msn2 causes cells to undergo cell-cycle arrest, suggesting a direct role for Msn2 in cell growth. Our studies elucidate the complex and inter-dependent mechanisms underlying gene expression changes and the process of "bet hedging" which occurs during stress.

Y471 Stress-dependent transcriptome changes serve to reallocate translational capacity during stress acclimation. *Yi-Hsuan (Elisha) Ho*[1], Evgenia Shishkova[2], Joshua Coon[2], Audrey Gasch[1]. 1) Laboratory of Genetics,University of Wisconsin- Madison, Madison, WI; 2) Department of Chemistry, University of Wisconsin- Madison, Madison, WI.

Proper response to environmental stress is pivotal for cells to survive and adapt to constantly changing environments. Activation of stress defense systems is often coupled with arrest of growth and cell cycle progression. The transcriptomic response of *Saccharomyces cerevisiae* to stress includes a common stress transcriptomic change called the environment stress response (ESR). The ESR includes induced expression of ~ 300 genes involved in stress defense and reduced expression of ~ 600 genes required for active growth, namely genes encoding ribosomal proteins and other translation machinery. There has been a debate if activation of the ESR, and in particular reduced expression of growth-promoting ESR genes, is an active response to stress or is merely an indirect byproduct of reduced growth and cell-cycle progression. Since stress responses are generally correlated with growth and division arrest, it is hard to deconvolute responses triggered directly by stress versus indirectly by growth reduction. Here, we decouple the response to external stress and growth control by following transcriptomic and proteomic changes of arrested cells upon stresses. Our results show that activation of the ESR, including repression of growth-promoting genes, is not associated with cell-cycle phase and is independent of growth arrest. Instead, arrested cells exposed to stress actively induce the ESR, even though they are no longer making significant biomass – this indicates that reduced expression of growth-promoting genes is not necessarily related to growth control. We are using mathematical modeling of transcriptome and proteome changes, along with polysome profiling to measured global translation rates, to understand the function of transcriptome changes under different conditions. Our results suggest that differences in transcript abundance during steady-state growth serve to set the levels of protein production required for a given growth rate, whereas changes in transcript levels during active stress help to reallocate translational machinery during acclimation.

Y472 Genetic factors controlling accelerated mRNA degradation during a nitrogen upshift. *Darach Miller*, David Gresham. New York University, New York, NY.

The release of yeast cells from nitrogen limitation triggers remodeling of cellular physiology to enable a faster rate of cell growth. While the population growth rate increase is not apparent until approximately 2 hours after, the nitrogen upshift triggers extensive transcriptional reprogramming on the timescale of minutes. Conserved signalling pathways, including TORC1 and Ras/PKA, are known to regulate steady-state growth, but the role of these pathways during the first few minutes of a nutrient upshift is unclear. Using the transcriptome to define the cellular state, we show that this upshift doesn't simply entail a shift from a slow growth steady-state to a fast growth steady-state, but rather proceeds through a transient alternative state. Using time-series modeling of transcriptome dynamics, we show evidence for a pulse of ribosomal component mRNA overproduction and accelerated degradation of high-affinity nitrogen transporter mRNAs, including *GAP1* and *DIP5*. To identify factors regulating this process, we used a branched DNA single molecule RNA FISH (smFISH) assay with flow cytometry to quantify transcript abundance in single cells during the upshift. Combining this assay with FACS and barcode sequencing (Barseq), we screened the pooled homozygous deletion collection for mutants defective in the accelerated degradation of GAP1 mRNA upon a nitrogen upshift. Our approach provides an effective means of screening for mutants defective in transcriptional dynamics that occur on the timescale of minutes.

Y473 P bodies regulate the rewiring of a transcription network by controlling the expression of the *YOX1* repressor during DNA replication stress. *R. Loll-Krippleber*, GW. Brown. Department of Biochemistry, University of Toronto, Toronto, Ontario, CA.

P bodies are RNA-protein granules that form in the cytoplasm of eukaryotic cells in response to various stresses and are thought to serve as sites of degradation and/or storage of mRNAs. We recently discovered that P bodies form in yeast in response to replication stress induced by HU (hydroxyurea), an anti-cancer drug that inhibits dNTP synthesis and slows DNA replication. P body components are required for cell survival of replication stress as mutants lacking key P body components Lsm1, Pat1 and Dhh1 are strongly sensitive to HU. Here, we aimed to identify mRNAs that are processed by P bodies during replication stress. First, we performed a transcriptome study on *lsm1*Δ cells upon acute HU exposure to identify mRNAs that are stabilized in the absence of a functional P body-dependent mRNA degradation pathway. Second, we used

an SGA-based suppressor screen to identify genes whose expression is toxic in the absence of Lsm1 and Pat1 during replication stress. We found that the transcriptome in *lsm1*Δ is altered both during normal growth and during replication stress, with more than 800 mRNAs being stabilized in *lsm1*Δ compared to wild type. Interestingly, we found that inactivation of the coding sequence of 6 of those 800 mRNAs was able to suppress HU sensitivity of *lsm1*Δ and *pat1*Δ strains suggesting that these genes encode mRNAs that need to be degraded in a P body dependent manner upon HU exposure. Among these we identified *YOX1*, a gene encoding a transcription repressor critical for the regulation of cell cycle and DNA replication genes. The suppressor effect of *yox1*Δ in *lsm1*Δ and *pat1*Δ cells is specific to HU and not to other drugs that induce DNA replication stress or to other environmental stresses. Consistent with P bodies regulating *YOX1* mRNA abundance, we found that *YOX1* mRNA localizes to P bodies and accumulates at P bodies in the absence of the mRNA exonuclease Xrn1. To gain insight into the role of Yox1 during replication stress, we identified 156 genes that are down-regulated upon *YOX1* overexpression. Among this set of targets, we notably found genes important for ribonucleotides biosynthesis (RNR genes), DNA unwinding during replication (MCM genes), cell cycle regulation and cytokinesis. Work is underway to identify which targets play a critical role during replication stress. Together, our data suggest a model where *YOX1* mRNA abundance is post-transcriptionally regulated by P bodies in order to reduce the level of the Yox1 transcription repressor and therefore prevent repression of genes necessary for survival of DNA replication stress.

Y474 Gene control by prion-like conformations of intrinsically disordered proteins. *D. F. Jarosz*, Richard She, Anupam Chakravarty, Curtis Layton, Johan Andreasson, William Greenleaf, James Byers. Stanford University, Stanford, CA.

Punctuated bursts of protein expression are common in biological systems. Yet whether these exert a lasting influence on future generations is largely unknown. We tested this by transiently overexpressing virtually all open reading frames in *Saccharomyces cerevisiae*. Strikingly, expression of nearly fifty intrinsically disordered proteins (IDPs) created heritable new traits that persisted after overproduction was stopped. The proteins were strongly enriched in RNA binding proteins (RBPs) and transcription factors (TFs). The inheritance patterns of these traits resembled protein-based genetic elements, known as prions. RBPs control the fate of nearly every transcript in a cell, but no existing approach for studying these post-transcriptional gene regulators combines transcriptome-wide throughput and biophysical precision. We used commonly available hardware to generate a uniform and highly redundant array of RNA transcripts, spanning an entire genome, on an Illumina MiSeq chip. We harnessed this transcribed genome array (TGA) to identify hundreds of new targets of Vts1/Smaug, which coordinates the degradation of maternal RNAs during development and emerged as a robust hit in our screen. This approach provided nucleotide resolution and direct measurements of affinity and dissociation in a single experiment, supplanting prior knowledge of determinants driving Vts1 substrate recognition. Acquisition of the [*VTS1*$^{+}$] prion enhanced the decay rates of target mRNAs and expanded the protein's substrate repertoire. The capacity to self-template was conserved in *Drosophila* and human Smaug proteins. Our data force a re-examination of the mechanism of Vts1/Smaug-mediated gene regulation, which was thought to occur via binding to 3'-UTRs from a handful of targeted studies. Instead, we found that binding throughout the transcript resulted in target degradation. Moreover, the idealized equimolar binding landscape of the TGA revealed previously unknown roles for Vts1/Smaug in the birth of new genes from proto-ORFs and in the regulation of stress responses. Our findings transform our understanding of Vts1/Smaug function, and have important implications for the many other IDPs involved in eukaryotic gene control.

Y475 Parallel pathways for export of tRNAs from the nucleus to the cytoplasm. *Anita K. Hopper*[1], Kunal Chatterjee[1], Jingyan` Wu[1,2], Shubhra Majumder[1]. 1) Ohio State Univ., Columbus, OH; 2) Stanford Univ., Palo Alto, CA.

Appropriate biogenesis and subcellular trafficking of tRNA are essential for decoding the genome and for regulating the proteome in response to nutrient availability and stress. Hundreds of gene products function in tRNA biology and mutations in numerous of these gene products cause a variety of human disorders ranging from metabolic diseases, to neuromuscular diseases, and to cancer. Yet, there is a very incomplete understanding of tRNA biology. To address this information gap, we conducted a screen of nearly the entire essential and unessential yeast proteome and identified 162 novel proteins that function in tRNA biology (Wu et al., 2015). Although we identified gene products that function in virtually every step of tRNA biosynthesis and subcellular dynamics, we are particular interested in those proteins that function in tRNA nuclear export because it is essential that tRNAs be efficiently transported to the cytoplasm where protein synthesis occurs, but mutants missing the known tRNA nuclear exporters, *los1Δ*, *msn5Δ*, and *los1Δ msn5Δ* are perfectly viable. Surprisingly, we identified Mex67 (vertebrate TAP), Mtr2 (vertebrate p15), and Crm1 (vertebrate Exportin-1) as potential tRNA nuclear exporters. Previous studies in yeast and vertebrate cells have shown that Mex67 and Mtr2 form heterodimers that function in mRNA nuclear export, whereas Crm1 functions in nuclear export of proteins possessing a leucine-rich NE motif. Three lines of evidence support the role of these proteins in tRNA nuclear export: (1) as determined by Northern analysis, at the nonpermissive temperature, *mex67-5*, *mtr2-x*, and *crm1-1* ts mutants each accumulate unspliced tRNAs and (2) as determined by FISH, each mutant has enhanced tRNA nuclear pools; (3) furthermore, *los1Δ* and *crm1-1* have synthetic growth defects and Mex67 can completely substitute for Los1 when it is over-expressed in *los1Δ* cells. Thus, it appears that there are at least 3 parallel pathways that function to export tRNAs from their site of synthesis in the nucleus to their site of function in the cytoplasm, underscoring genetic redundancy for this essential cellular process. Preliminary data indicate that Mex67/Mtr2 and Crm1 are more error prone in tRNA nuclear export than Los1, raising questions regarding tRNA quality control during the nuclear export process. We are currently conducting *in vivo* biochemical analyses to determine whether tRNAs can be cross-linked to Mex67/Mtr2 and/or Crm1 as they exit the nucleus.

Y476 Yeast telomerase and RNase P/MRP: when two different worlds come together. *N. Laterreur*[1*], B. Lemieux[1], A. Perederina[2], JF. Noël[1], ML. Dubois[1], AS. Krasilnikov[2], RJ. Wellinger[1]. 1) Université de Sherbrooke, Sherbrooke, Québec, CA; 2) Pennsylvania State University, PA, USA.

Telomerase is a specialized ribonucleoprotein that maintains genome integrity by adding telomeric DNA to the ends of eukaryotic chromosomes. For many years now, it has been established that the telomerase complex is minimally composed of an RNA molecule, Tlc1, and a reverse transcriptase called Est2p. In the cell, Tlc1 serves as a scaffold for many other proteins (Est1p, Est3p, yKu, Sm_7) and add telomeric repeats at shortened chromosome ends by reverse transcribing an essential template within the RNA molecule.

Using mass spectrometry analysis and a native system to purify Tlc1-bound proteins, we have been able to identify new partners for *Saccharomyces cerevisiae* telomerase. These proteins are components of the RNase P/ RNase MRP complexes; two related, highly conserved and essential RNPs that are involved in the processing of tRNA, rRNA and certain mRNAs. These ribonucleoproteins both contain a catalytic RNA subunit (Rpr1 for RNase P and Nme1 for RNase MRP) that is bound by a group of proteins.

We report that the Pop1, Pop6 and Pop7 proteins of the RNase P/MRP complexes bind to yeast telomerase RNA and are essential constituents of the telomerase holoenzyme. The trio binds to a specific and highly conserved RNA domain present in Tlc1. This domain, called P3 domain, is also shared by the RNAs of RNase P/MRP. The results also show that Pop1/Pop6/Pop7 function is to maintain the essential components Est1 and Est2 on the RNA in vivo. Consistently, addition of Pop1 allows for telomerase activity reconstitution with wild type telomerase RNA in vitro. Thus, the same chaperoning module has allowed the evolution of functionally and, remarkably, structurally distinct RNPs, telomerase and RNases P/MRP, from unrelated progenitor RNAs.

Note: N. Laterreur & B. Lemieux contributed equally to the work..

Y477 Coordinated regulation of heterochromatin inheritance by Daf1/Dpb4 complex. *Fei Li*[1], Haijin He[1], Yang Li[2], An-Yun Chang[3], Qianhua Dong[1], Feng Gao[2], Zongxuan Chi[1], Min Su[2], Rob Martienssen[3], Yu-hang Chen[2]. 1) Department of Biology, New York University, New York, NY; 2) Institute of Genetics and Developmental Biology, Chinese Academy of Sciences, Beijing, China; 3) Cold Spring Harbor Laboratory, Cold Spring Harbor, NY.

Histone H3 lysine 9 (H3K9) methylation and histone hypoacetylation are two conserved epigenetic hallmarks of heterochromatin. How H3K9 methylation and histone hypoacetylation are faithfully inherited and how these two processes are coordinately regulated during replication remain poorly understood. We previously showed that the inheritance of H3K9 methylation during DNA replication depends on the catalytic subunit of DNA Polymerase epsilon, Cdc20/Pol2, in fission yeast. Here we show that two histone-fold subunits of Pol epsilon, Daf1/Dpb3 and Dpb4, in fission yeast form a heterodimer that plays a crucial role in the inheritance of histone hypoacetylation. Our findings reveal a previously unrecognized link between histone deacetylation and H3K9 methylation, and suggest a mechanism for how two processes are coordinated during replication. Surprisingly, we found that Dpb4 associates with both positive and negative regulators of heterochromatin silencing. Particularly, we show that SWI/SNF chromatin remodeling complex subunits interact with Daf1-Dpb4 dimer and act an anti-silencing factor essential for heterochromatin disassembly. Upon solving the 1.9 Å crystal structure of the Daf1-Dpb4 complex we observed that Daf1 and Dpb4 form an H2A-H2B-like heterodimer, and gained further insight into the role of this dimer in chromatin regulation. To our knowledge, this represents the first time a crystal structure has been resolved for Dpb3-Dpb4. Together, our findings indicate that the Daf1-Dpb4 complex provides a platform for the recruitment of chromatin modifiers and remodelers during DNA replication, which in turn mediate the disassembly and re-assembly of heterochromatin and ensure the accurate perpetuation of heterochromatin marks.

Y478 The Replication Kinase Cdc7 Marks Histones to Regulate Biosynthesis Genes. *P. A. Grant*[1], E. Sendinc[1], S. A. Hoang[1], X. Xu[1], M. Zakari[2], J. L. Gerton[2], S. Bekiranov[1]. 1) University of Virginia School of Medicine, Charlottesville, VA; 2) Stowers Institute for Medical Research, Kansas City, MO.

Post-translational histone modifications (PTMs) play important roles in regulating various DNA-templated cellular functions including transcription, DNA damage repair, DNA replication and telomeric silencing. Histone H3 Threonine 45 phosphorylation (H3T45ph) is a modification that is enriched during S-phase of the cell cycle in *Saccharomyces cerevisiae* and is carried out by the kinase Cdc7-Dbf4 (DDK) *in vivo* and *in vitro.* To understand the function of this mark we identified the genomic H3T45ph locations by performing chromatin immunoprecipitation followed by high throughput sequencing (ChIP-Seq) of wild-type budding yeast cell chromatin. Remarkably, this PTM is observed not only at origins of DNA replication, but is also uniquely distributed on the promoters of highly transcribed RNA polymerase I, II and III-regulated genes dedicated to protein synthesis and glycolysis. Here we show that H3T45 phosphorylation, mediated by Cdc7-Dbf4, is required for polymerase recruitment and full expression of ribosome protein (RP) and tRNA genes as well as for the regulation of cohesin loading. Collectively, we identify an unexpected gene regulatory function for the DNA-replication kinase Cdc7-Dbf4 and identify a novel histone modification regulating the protein biosynthesis gene machinery.

Y479 An oncometabolite disrupts epigenetic processes and increases gene silencing in *Saccharomyces cerevisiae*. *Ryan Janke*, Jasper Rine. University of California, Berkeley, Berkeley, CA.

Aberrant accumulation of the metabolite D-2-hydroxyglutarate promotes certain types of cancers, but much uncertainty remains regarding which specific cellular processes are impacted by the oncometabolite to promote tumor growth. The structures of α-ketoglutarate and D-2-hydroxyglutarate are sufficiently similar that D-2-hydroxyglutarate can act as a competitive inhibitor of α-ketoglutarate-dependent enzymes both *in vitro* and *in vivo*. Several key epigenetic regulators, including members of the TET family of DNA demethylases and Jumonji histone demethylases, are among the known enzymes inhibited by D-2-hydroxyglutarate. Separating the effects of DNA and histone hypermethylation has been a challenge to the field. *Saccharomyces cerevisiae* naturally lacks DNA methylation machinery and thus provides a unique

opportunity to study exclusively the effect of D-2-hydroxyglutarate accumulation on histone demethylation. Here, we have demonstrated that mutations analogous to those that cause D-2-hydroxyglutarate accumulation in human tumors recapitulated the effect in yeast. We have additionally uncovered a novel pathway for naturally producing and degrading D-2-hydroxyglutarate in yeast. Through a combination of genetic and molecular analyses, we found that D-2-hydroxyglutarate accumulation increased silencing of genes within heterochromatin. This effect was specifically mediated through D-2-hydroxyglutarate-inhibition of histone demethylase enzymes specific for H3K36 methyl marks. Our work has uncovered a mechanism by which the impact of D-2-hydroxyglutarate is leveraged by disrupting a widespread epigenetic regulatory process that leads to altered chromatin states and transcription. Inspired by these results we have expanded our study and uncovered multiple unexpected nodes in metabolism that impact heterochromatin stability, which will be discussed.

Y480 Mechanistic insight into the role of the Paf1 complex in histone modification. *S. Branden Van Oss*[1], Margaret K. Shirra[1], Alain R. Bataille[2], Adam D. Wier[1], Kuangyu Yen[2], Vinesh Vinayachandran[2], Andrew P. VanDemark[1], B. Franklin Pugh[2], Karen M. Arndt[1]. 1) University of PIttsburgh, Pittsburgh, PA; 2) Penn State University, State College, PA.

Post-translational modification of the core histones represents an important level of epigenetic regulation of eukaryotic transcription. One such modification, the monoubiquitylation of histone H2B lysine 123 in yeast (H2B K123ub), is a well conserved mark implicated in activation of transcription, silencing of heterochromatic regions, establishment of other histone modifications, and regulation of development and differentiation in higher eukaryotes. The five-subunit yeast Paf1 complex (Paf1C), an important regulator of all stages of transcription, is required for the establishment of H2B K123ub, largely through the activity of its Rtf1 subunit. We have identified a 66-amino acid region in Rtf1, the Histone Modification Domain (HMD), which is capable of promoting H2B K123ub *in vivo*, even in a strain that lacks all Paf1C subunits. Aided by our crystal structure of the HMD, we constructed a large collection of HMD mutant strains and identified residues important for H2B K123ub, H3 K4 and H3 K79 methylation, and telomeric silencing. Guided by analysis of these mutants, we performed *in vivo* crosslinking experiments using the phenylalanine analog *p*-benzoyl-L-phenylalanine (BPA). Exposure of cells to ultraviolet radiation induced site-specific crosslinks with a short linker distance, allowing us to identify proteins directly interacting with the HMD. Among the collection of proteins that crosslinked to the HMD, we identified the ubiquitin conjugase for H2B K123 ubiquitylation, Rad6. The residues that crosslink to Rad6 lie along one face of an alpha helix within the HMD. Importantly, a mutation that inactivates the HMD eliminates the Rtf1-Rad6 crosslink. To further probe the functions of the Rtf1 HMD and the entire Paf1C, we have used ChIP-exo technology to map the occupancy of Paf1C subunits, as well as the isolated HMD and components of the H2B K123 machinery, with high resolution genome-wide. The results of these studies support the idea that Paf1C occupancy is dictated by its interactions with the RNA polymerase II elongation machinery, but the Rtf1 HMD localizes to histone H2B. Finally, using a minimal *in vitro* ubiquitylation assay, we have shown that the HMD stimulates the specific *in vitro* ubiquitylation activity of Rad6 in a manner that is dependent on the ubiquitin ligase Bre1. Collectively these results provide new mechanistic insight into the critical role of the highly conserved yeast Paf1C in establishing histone modifications during transcription elongation.

Y481 Protein abundance control by non-coding antisense transcription. *F. Huber*[1], D. Bunina[1], I. Gupta[2], A. Khmelinskii[1], M. Meurer[1], P. Theer[1,3], L. Steinmetz[2], M. Knop[1,3]. 1) University of Heidelberg, Heidelberg, DE; 2) European Molecular Biology Laboratory (EMBL), Heidelberg, DE; 3) Deutsches Krebsforschungszentrum, Heidelberg, DE.

High throughput studies have revealed the pervasive nature of transcription in eukaryotic genomes, resulting in the identification of a multitude of non-coding RNAs (ncRNAs). In yeast, a substantial number of ncRNAs overlap protein-coding genes in antisense direction. While numerous reports on antisense-dependent gene regulation have been published, most studies focus on a few selected cases or rely on correlations derived from RNA-based high throughput experiments. Therefore, our understanding of which antisense RNAs exert a biological function and whether functional antisense RNAs share certain features remains incomplete. To address these shortcomings, we developed a genetic strategy to specifically abrogate antisense transcription in selected genomic loci and to directly measure the resulting impact on sense protein levels using GFP as a reporter. To gain a systematic understanding, we applied this technique to 162 yeast genes known to be overlapped by antisense RNAs. Subsequently, we used quantitative high throughput microscopy to score the effects of each tested antisense transcript on sense protein abundance under several growth conditions, thus discriminating between functional and non-functional antisense RNAs. We found that only a minority of the genes (20%) were affected by antisense transcription and that in those cases regulation was generally weak and led to a reduction in protein amounts. Interestingly, antisense regulated genes also showed reduced protein expression noise. When investigating whether certain features distinguish functional from non-functional antisense RNAs we found that the functional antisense transcripts were more likely to extend into the transcript start site of the sense. The effect of antisense increased at high antisense RNA levels but was reduced at high sense RNA levels. While we could not identify any specific sequence motifs, we found that antisense regulated genes had increased H3K4 di- and trimethylation levels. Our data shed light on the general principles that underlie antisense-mediated gene expression regulation and will provide a rich resource for detailed mechanistic studies.

Y482 Promoter scanning during transcription initiation in *Saccharomyces cerevisiae*: Pol II in the "shooting gallery". *Craig Kaplan*. Texas A&M University, College Station, TX.

Transcription initiation is the first step in gene expression. RNA Polymerase II (Pol II) is recruited to promoter DNA by activators, and together with core promoter elements and general transcription factors (GTFs), Pol II initiates transcription. Where Pol II initiates and how efficiently it does so is determined by the biochemical properties of the transcription machinery, and how it interacts with promoter architecture. In *Saccharomyces cerevisiae*, Pol II finds transcription start sites (TSSs) by scanning a promoter in a directional fashion from upstream to downstream. As in higher eukaryotes, many TSSs are used at any individual promoter. We wish to understand the mechanisms by which TSSs

are identified, and how TSS usage and overall efficiency are shaped by promoter architecture (promoter DNA sequence, the spatial relationship between promoter elements, and chromatin structure). To this end, we have used alteration of Pol II and GTF activities to perturb the initiation process. We find that alteration of TFIIH activity (*SSL2*-encoded subunit) affects TSS selection differently than alteration of Pol II (large subunit, encoded by *RPO21*), TFIIB (*SUA7*), or TFIIF (*TFG2*-encoded subunit) activity. Furthermore, we find that promoter scanning appears to operate at all yeast promoters, regardless of promoter class. However, promoter scanning appears to be differentially affected by promoter architecture. We integrate our observations with previous data into a model for Pol II initiation in yeast – the "shooting gallery". In this model, Pol II catalytic activity, and the rate and processivity of the engine for Pol II scanning, TFIIH, determine the distribution of TSSs and their usage levels together with promoter sequence.

Y484 Pathway transplantation into yeast as a model for human disease. *Neta Agmon*, Jef D. Boeke. NYULMC Institute for Systems Genetics, New York, NY.

Decades of research have led to the development of a numerous high throughput libraries and technologies for screening in yeast. In combination with the most resent advances in synthetic biology, yeast cells can be manipulated to serve as a "factory" for producing a desired product or as a tool to study cellular pathways. We evaluated whether we could express an entire human metabolic pathway in yeast. We chose the purine biosynthesis pathway as our first working model. It is a highly conserved pathway from yeast to humans. In humans there are >20 disorders associated with the pathway that have a variety of symptoms. Importantly, most of these diseases lack any established treatment. However, in some cases the evidence linking mutations in the gene to disorders is rather thin. We propose to use yeast for expressing human mutant alleles of human diseases in order to study whether these mutations actually impact the ability to biosynthesize adenine or other purines and if so, their effect on the cell's entire metabolic network and for screening for possible treatments. Using a synthetic biology approach, we are swapping the entire purine biosynthesis network of the yeast with the cognate human genes. We have engineered a yeast strain "humanized" for the full *de novo* adenine biosynthesis pathway. We deleted all of the yeast genes involved in the pathway and complemented them using a neochromosome expressing the human reading frames under the transcriptional control of their cognate yeast promoters and terminators. The "humanized" yeast strain shows growth in the absence of adenine, indicating complementation of the yeast pathway by the full set of human proteins. While the strain with the neochromosome is indeed prototrophic, it grows slowly in the absence of adenine. Dissection of the phenotype revealed that the human ortholog of *ADE4*, PPAT, shows only partial complementation. We have used several strategies to understand this phenotype, pointing to a possible fundamental difference between the human and the yeast pathways. We also introduced mutations from patients into the human genes to examine their effect on the "humanized" strain. Surprising results suggest that certain missense mutations presumed to underlie human disease conditions have no detectable impact on adenine biosynthesis in yeast. This could be explained by either a second function for the affected protein or an incorrect interpretation of a mutation. Other mutations recapitulate metabolic aspects of the known human disorder LND. Finally, the purine metabolic network can serve as a proof of principle for our ability to take human diseases and the associated pathway/gene networks and establish new yeast models for human disease.

Y485 Genetic and environmental backgrounds constrain the course of evolutionary rescue by compensatory mutations. *Véronique Hamel*, Marie Filteau, Marie-Christine Pouliot, Isabelle Gagnon-Arsenault, Alexandre K. Dubé, Christian R. Landry. Département de Biologie, PROTEO and Institut de Biologie Intégrative et des Systèmes (IBIS), Université Laval, Québec, Qc, Canada.

Deleterious mutations segregate and often fix in small populations during the course of evolution. These deleterious mutations can be compensated for by secondary mutations known as compensatory mutations. We examined if the trajectory of compensatory evolution to a strongly deleterious mutation is dependent on the environment and the genetic background in which compensatory evolution takes place. We performed an evolutionary rescue experiment in a yeast model for the Wiskott-Aldrich syndrome (mutation in *LAS17*) in two genetic backgrounds and two carbon sources. We found that compensatory mutations tend to be overrepresented in the physical interaction network surrounding Las17p, showing that protein interaction partners are prime targets for compensatory mutations. In addition, we found that multiple aspects of the evolutionary rescue outcome depend on the genotype, the environment and their combination. Specifically, the compensatory mutation rate and type, the molecular rescue mechanism, the genetic target and the associated fitness cost varied across contexts. Overall, our results show that the course of evolution following the fixation of a deleterious allele is highly contingent on the initial conditions in which a deleterious mutation occurs.

Y486 The genomic repercussions of *RAD5* overexpression. *Robert Reid*[1], Eric Bryant[2], Ivana Sunjevaric[1], Rodney Rothstein[1]. 1) Columbia University Medical Center, New York, NY; 2) Columbia University, New York, NY.

The human *HLTF* gene is located on chromosome 3q24 and is frequently amplified in squamous cell lung carcinomas. HLTF is the human ortholog of the *Saccharomyces cerevisiae RAD5* gene, a DNA helicase and ubiquitin ligase that functions in post replication DNA damage repair. Overexpression of *RAD5* results in slow growth and genome instability. We used Selective Ploidy Ablation (SPA), a rapid high throughput plasmid screening protocol, to identify *Saccharomyces cerevisiae* genes whose function becomes essential when *RAD5* is overexpressed. Many DNA replication and DNA double strand break repair genes were identified covering multiple steps in these processes, including replication fork protection, lagging strand DNA synthesis, DNA end resection, homology dependent strand invasion and resolution of Holliday junction

intermediates. Curiously, genes regulating the process of post replication repair (PRR) are unaffected in the screen. Cells encountering DNA damage that results in replication fork stalling enter the PRR pathways via modification of PCNA/Pol30 by ubiquitylation. Using multiple mutant backgrounds, we confirmed that ubiquitylation of PCNA is not necessary for the growth suppression resulting from *RAD5* overexpression. Since Rad5 is a multidomain polypeptide containing helicase, ubiquitin ligase and DNA binding functions, we investigated the contribution of these domains to *RAD5* toxicity. Mutant protein constructs were screened using the high throughput SPA method to transfer each *RAD5* mutant into an array of sensitized mutant strains. Automated quantitative analysis of the growth curves was used to define the effects of individual *RAD5* mutants in strains deficient for specific repair functions. We find that the individual domains of overexpressed *RAD5* have separate contributions to cell toxicity in different genetic backgrounds. For example, we have uncovered instances where deletion of a specific Rad5 domain increases toxicity, suggesting that it normally performs a protective function. As the function of Rad5 is conserved in human cells, the identified SDL interactions may help to develop targeted therapeutic approaches for squamous cell carcinomas of the lung.

Y487 Functional characterization of human gene alleles using inter-species genetic approaches. *Q. Zhong*, S. Chen, I. Haider, M. Islam, R. Santhnakrishnan, S. Ju. Wright State University, Dayton, OH.

Genome-sequencing technologies bring extraordinary opportunities in identifying genetic variations. Interpretation of functional consequences of genetic variations in a give individual, however, remains to be a daunting challenge. This is in part due to our limited understanding of the effect of any single genetic variation on cellular and organismal function. More difficult is to interpret functional impact of multiple genetic changes simultaneously occurring in an individual. We recently discovered that, despite vast evolutionary separation, human and yeast proteins still widely retain the ability to mediate inter-species protein-protein interactions. Surprisingly, such human-yeast inter-species interactions are not limited to proteins conserved between the two species, but frequently correspond to functional links between proteins mediating new species-specific functions and conserved ancestral cellular machinery. Based on these findings, we have developed three experimental platforms to systematically measure effects of human genes on cellular functions and to rapidly classify genetic interactions between human gene alleles using yeast cells as the "mediator" host. Our data demonstrates the feasibility and value of using yeast a a model system to characterize evolutionarily conserved human gene function. Such inter-species genetic approaches may help identify both genetic and environmental factors that modulate complex phenotypes in human disease.

Y488 Genome-Wide Analysis in Yeast to Identify Molecular Targets Promoting Readthrough. *Mert Icyuz*[1*], John L. Hartman, IV[1], Eric J. Sorscher[2]. 1) University of Alabama at Birmingham, Birmingham, AL; 2) Emory University, Atlanta, GA.

Nonsense mutations, single nucleotide base changes that result in an in frame premature termination codon (PTC), make up ~20% of the ~43,000 disease associated mutations residing in gene coding regions and are responsible for ~11% of all inherited human diseases. Restoring functional protein by inducing readthrough of PTCs has been accomplished using aminoglycosides that have been considered as potential therapies. The overall efficacy of readthrough achieved with and the toxicity caused by currently available compounds has not been desirable. The goal of our project is identify genes that promote readthrough and we have employed cystic fibrosis, which is an autosomal recessive disease caused by loss of function of the cystic fibrosis transmembrane conductance regulator (CFTR), as model disease. Previously, we showed that Yor1 (Yeast Oligomycin Resistance-1, a member of the ABC gene family) could serve as a robust model for genome-wide phenomic analysis of CFTR. The approach demonstrated evolutionary conservation of gene-gene interactions between yeast and human for proteins that regulate CFTR-ΔF508 biogenesis; and resulted in discovery of novel targets for correction of CFTR misfolding. The CFTR-G542X mutation is the most common premature termination codon in CFTR, and the second most common CF-causing allele. We have introduced a homologous mutation of CFTR-G542X, G704X, in YOR1, and using growth on oligomycin as readout show that yor1-G704X behaves in a similar fashion to the yor1-null allele. This data indicates very little or no full-length protein is expressed, analogous to CFTR-G542X. In the presence of G418, an aminoglycoside shown to restore partial CFTR function in mammalian cell lines, we observed oligomycin resistance specifically mediated by the Yor1-G704X mutant, establishing that yor1- G704X is suitable as a reporter for genome-wide yeast phenomic screening and identification of molecular targets that allow readthrough of nonsense variants. Among the hits produced by our unbiased genome-wide phenotypic screen with Yor1-G704X are the members of nonsense mediated decay (NMD) pathway, Nam7 & Upf3. Suppression of NMD pathway was previously shown to lead to recovery of CFTR protein function. We identified some members of the 20S proteasome as modifiers of Yor1-G704X function. These candidates will be further tested in cell lines for CFTR protein function with siRNA knockdown. Resulting genes and pathways will serve as a basis for new therapeutic strategies to achieve functional CFTR expression in CF patients carrying premature stop codons.

Y489 Systematic functional analysis of resistance-conferring mutations. *L. H. Wong*[1], S. Sinha[1], J. R. Bergeron[2], G. Giaever[1], P. Flaherty[3,4], C. Nislow[1]. 1) University of British Columbia, Vancouver, BC, Canada; 2) University of Washington, Seattle, WA, USA; 3) Worcester Polytechnic Institute, Worcester, MA, USA; 4) University of Massachusetts, Amherst, MA, USA.

The emergence and prevalence of drug resistance is an inevitable consequence of the biological response to selective pressures like those that accompany drug therapies. We therefore developed an unbiased and systematic screen to identify the functional impact of drug resistant variants in a fast and cost-effective manner. Current methods to understand and predict drug resistance often require significant time, computational power and clinical constraints. These challenges are exacerbated by the lack of statistical methods to accurately call allele frequency variants.

By combining deep sequencing and a Bayesian statistical model we provide a comprehensive survey of drug resistance alleles from complex variant populations. Using dihydrofolate reductase (DFR1), the target of methotrexate chemotherapy as a benchmark we identified and validated functional alleles correlated with methotrexate (MTX) resistance in yeast. This massively parallel strategy allowed us to catalog alleles

with dominant resistance phenotypes independent of pre-existing competitive fitness traits. We confirmed 10 MTX-resistant missense mutations in DFR1/dfr1Δ heterozygotes, 2 of which also confer growth advantages and 3 hypomorphic alleles. In parallel we confirmed 8 functional missense mutations in the haploid dfr1Δ strain. The recovery of these distinct dfr1 MTX resistant-alleles underlines the power of using genetic-based assay in S. cerevisiae to dissect complex functional determinants of drug resistance. Because many of these novel resistant variants map to structurally conserved binding pockets within the Dfr1 active site, this approach should yield insight into the mechanistic differences between antifolate resistant alleles and folate metabolism.

Y490 A trade-off between invasion and sexual reproduction is mediated by the DNA-binding mechanism of a conserved transcription factor. *M. W. Dorrity*[1], J. C. Cuperus[1,2], C. Queitsch[1], S. Fields[1,2]. 1) University of Washington, Seattle, WA; 2) Howard Hughes Medical Institute, Seattle, WA.

Complex traits are challenging to study because there are numerous underlying genetic factors, interactions between genes and the environment, and interactions between the traits themselves. In the yeast *Saccharomyces cerevisiae,* two important complex traits – invasive growth and sexual reproduction – rely on a single transcription factor, Ste12, for proper expression. We used deep mutational scanning to examine the interaction between these complex traits by analyzing single amino acid perturbations in the DNA-binding domain of Ste12. Because alternative modes of DNA binding are implicated in the diverse functions of Ste12, we focused on a critical segment of the protein that is likely to contact DNA. By selecting for the ability of yeast either to invade or to mate, we sought to find sites in the protein needed either for both traits equally or for one at the expense of the other. We identified residues within the DNA-binding domain of Ste12 that could not be mutated without loss of mating, while mutations at these same positions still allowed invasion. In fact, some mutations even increased the ability of cells to invade at the cost of mating, revealing that a trade-off between invasion and sexual reproduction is encoded within a short segment of Ste12's DNA-binding domain. To explore the role of the environment, we identified mutations that increase the dependence of mating on temperature. We found that temperature-dependent variation overlaps with Hsp90-dependent variation, implying that Ste12's DNA-binding function may be stabilized by chaperones. Given the role of Ste12 as the ultimate recipient of diverse signals and the results of our mutational analysis, we suggest that flexibility in DNA-binding may be critical to Ste12 function. These findings increase our understanding of the interactions between complex traits, while also revealing a possible mechanism for the evolutionarily conserved link between invasion and sexual reproduction.

Y491 Meiotic Crossing Over Requires Attenuation of an Intrinsic Degron in the MutS Homolog Msh4. *Neil Hunter*[1], Wei He[1], Prasada Rao[1], Shangming Tang[1], Nikhil Bhagwat[1], Dhananjaya Kulkarni[1], Maria Chang[1], Christie Hall[1], Xiangyu Chen[2], Nancy Hollingsworth[2], Lepashki Singh[3], Petr Cejka[3]. 1) Univ California, Davis, Davis, CA and the Howard Hughes Medical Institute; 2) Stony Brook Univ., New York, NY; 3) University of Zurich, Zurich, Switzerland.

Crossing over is essential for the faithful disjunction of homologous chromosomes during the first meiotic division. Regulatory processes that control crossing over remain poorly characterized. Our recent studies indicate that regulated protein destruction is a key aspect of crossover control. Here, we show that the pro-crossover function of the conserved meiosis-specific recombination factor, MutSγ (a complex of Msh4 and Msh5), requires its stabilization via phosphorylation. Our analysis reveals that Msh4 is an intrinsically unstable protein by virtue of a disordered domain in its N-terminus, which targets it for proteasomal destruction. The degron activity of this domain is attenuated by its phosphorylation, which is essential for the crossover activity of MutSγ. Msh4 phosphorylation requires the initiation of recombination and chromosome synapsis. These and other genetic requirements suggest that Msh4 phosphorylation occurs *in situ* at sites of recombination. Consistent with this idea, we show that Msh4 phosphorylation is mediated by the chromatin-based kinase, DDK (Dbf4-Dependent Kinase, a.k.a. Cdc7-Dbf4). We suggest a model in which the intrinsic instability of a subset of meiotic recombination factors enables crossover control via differential stabilization at crossover versus non-crossover recombination sites.

Y492 The ascus persists after post-germination budding and influences bud-vs-mate decisions in *S. cerevisiae*. *M. A. McMurray*, L. R. Heasley. Univ Colorado Anschutz Medical Campus, Aurora, CO.

Diploid *Saccharomyces cerevisiae* cells undergo meiosis and sporulation during nutritional deprivation. Unlike many other fungi, *S. cerevisiae* spores remain encased in the ascus, a sac-like structure derived from the vegetative cell wall of the pre-meiotic mother cell, unless environmental conditions degrade the ascus and promote spore dispersal. Upon exposure to nutrients, spores germinate (i.e., partially break down the spore wall) and either begin mitotic proliferation immediately, or mate with other cells and then proliferate mitotically. Homothallic spores have the additional option of mating-type switching after the first haploid budding event and then mating with the bud or its progeny. If the original diploid cells are heterozygous at important loci, these three options (mate, bud, or bud/switch/mate) have drastically different consequences for the possible allelic combinations following germination and, thus, for fitness. Although this basic question has been considered from a genetic perspective for many decades, the basic cell biology of germination is surprisingly understudied. It is widely assumed in the literature that the act of budding reflects or induces "global" breakdown of the ascus wall that liberates all constituent spores simultaneously. Strikingly, we find, instead, that budding and mating reflect "local" remodeling of the ascus, such that individual spores can bud or mate "out" of the ascus without liberating their sisters. To address the influence of ascus persistence during germination on the bud-vs-mate decision, we developed three independent assays: (i) the Sex with Sister Selection (SwiSS), which allows colony growth only when a spore mates with its sister; (ii) the Germination Abstinence eNforcer (GermAN), which allows colony growth only when a spore avoids mating; and (iii) appropriate colony color markers to visualize mating between sister spores as half-sectored colonies. These approaches demonstrate that an intact ascus promotes mating as the first post-germination event. Together with our observations of ascus perdurance after budding, these

findings uncover a hitherto unappreciated role for the ascus in the control of genetic stability through the yeast life cycle. As vegetative conditions influence cell wall durability, ascal control of post-germination events may create a regulatory circuit in which environmental conditions prior to sporulation dictate the duration of ascus persistence and, consequently, the extent of intra-ascus mating. In addition to the poorly understood *S. cerevisiae* ecological niches, these mechanisms are likely at play in certain industrial settings, such as vinification.

Y493 Kar4p regulates meiosis at both the transcriptional and translational levels. *M. D. Rose*, M. Remillard, A. Sporer. Princeton University, Princeton, NJ.

Yeast cells undergo several pathways of differentiation, including mating and meiosis. Whereas mating is regulated by exposure to pheromones, meiosis is regulated by integration of multiple signaling pathways that assess the cellular state and nutritional environment. Kar4p is required for both mating and meiosis. Kar4p is a conserved member of the MT-A70 family of mRNA adenine-methyl transferases. In humans, mRNA methylation is carried out by the MT-A complex comprising METTL3, METTL14 and WTAP. In yeast, mRNA methylation is catalyzed by the MIS complex comprising Ime4p, Slz1p and Mum2p. Ime4p is homologous to METTL3 and Mum2p is homologous to WTAP. Although Kar4p is homologous to METTL14, it contains mutations in the active site that would render it inactive. During mating, Kar4p interacts with the transcription factor Ste12p to activate expression of genes required for nuclear fusion. However, Kar4p's role in meiosis was unknown. To analyze Kar4p's separate functions in mating and meiosis, we isolated 28 mating (Mat^-) or meiosis (Mei^-) specific mutations. The two sets of alleles map to non-overlapping surfaces on a predicted protein structure. All 13 Mat^- alleles abolished Kar4p's interaction with Ste12p. *kar4*Δ and the Mei^- alleles blocked entry into meiosis, prior to S-phase and recombination. Overexpression of Ime1p, the major meiotic transcriptional activator, suppressed the Mei^- defect. Transcriptional profiling revealed that ~100 Ime1p-dependent transcripts are strongly decreased and/or delayed in the *kar4*Δ mutant. Ime1p overexpression suppressed the *kar4*Δ early transcription defect. However, Ime1p overexpression was not sufficient to complete sporulation. Approximately half of the mutants were also defective for sporulation (Spo^-), becoming blocked after S-phase and recombination. The Spo^- phenotype was not correlated with Mat^- or Mei^- alleles, implying that the Spo^- alleles serendipitously affect yet another function of Kar4p. Overexpression of *RIM4*, a meiotic translational regulator, efficiently suppressed the Spo^- defect. Consistent with a translational role, Ime2p levels were strongly reduced in the *kar4*Δ Spo^- mutant, although *IME2* mRNA was expressed normally. Rim4p overexpression restored Ime2p expression to normal levels. Overexpression of both *IME1* and *RIM4* in *kar4*Δ cells allowed rapid and efficient sporulation, effectively recreating the transcriptional profile of wild-type. Taken together, these data suggest that Kar4p regulates meiosis and sporulation in two different ways, first by enhancing the activity of Ime1p at a subset of its transcriptional targets and second by enhancing the activity of Rim4p for the translation of Ime2p and other genes.

Y494 A cytokinesis checkpoint. *Eric Weiss*, Jennifer Brace. Northwestern Univ, Evanston, IL.

The steps of cell division happen in precise sequence, even though late processes often don't inherently require successful completion of preceding ones. In the final stage of division, for example, cells are cut into separate entities by strictly ordered morphological rearrangements of cytokinesis and abscission. It's not clear how cells enforce the exact sequence of these events. In budding yeast cell separation actomyosin ring contraction is closely coordinated with synthesis of a septum that's immediately degraded once it's completed. How do cells avoid destroying the septum before it's finished? We find that cytokinetic mutants that significantly delay septum formation are highly sensitive to overproduction of the cell separation chitinase Cts1 and are suppressed by *cts1*, indicating that proper control of the cell separation program is critical when septum formation is defective. A signaling system called the RAM network links *CTS1* transcription to mitotic exit. However, we find that transcription of septum destruction genes turns on just before actomyosin ring contraction, and that cells with defective septum synthesis produce the chitinase protein with normal timing but don't secrete it. The dependency of cell separation enzyme secretion on completion of cytokinesis requires Fir1, a largely intrinsically disordered substrate of the RAM network kinase Cbk1. Deletion of *FIR1* eliminates *Cts1* secretion delay in cytokinesis mutants, which exhibit strong negative genetic interaction with fir1. While the RAM network isn't required for anterograde membrane trafficking during growth, Cbk1 promotes secretion of chitinase. *Fir1* inhibits this Cbk1 function as well as other aspects of post-cytokinesis secretion. *Fir1* is normally quickly degraded during cell separation, disappearing from the cytokinesis site after actomyosin ring contraction, but is stabilized when septum formation is abnormal. Thus, an unknown mechanism links Fir1's inhibition of septum destruction enzyme delivery to status of septum formation. Eukaryotes have evolved checkpoint systems that actively block late processes until preceding ones are complete, enforcing dependencies among otherwise mechanistically independent cell cycle events. We propose that a novel checkpoint protects the integrity of cytokinesis by blocking irreversible late steps until the process's early stages are finished, and that Fir1 is a key part of this checkpoint in budding yeast.

Y495 The CWI Pathway Regulates Cell Wall Degradation During Mating. *A. Hall*, M. Rose. Princeton University, Princeton, NJ.

Cell fusion is a universal process in eukaryotic organisms. We are studying the process of cell fusion using mating of the budding yeast, *S. cerevisiae.* To mate, haploid yeast cells detect each other by pheromone signaling, polarize their growth toward the mating partner, and then fuse to form a diploid zygote. The initial step in yeast fusion is the removal of the cell wall between the mating partners, to allow plasma membrane fusion. Because the improper timing or location of cell wall degradation would lead to cell lysis and death, the initiation of cell fusion is a highly regulated process. The signal(s) that indicate when and where cell wall degradation should occur have not been identified. Previous hypotheses proposed that cells may require a high local concentration of mating pheromone, physical contact, an as yet unidentified protein receptor, or a combination of all three. Several pieces of evidence suggest that the cell wall integrity (CWI) pathway may play a role in this signaling. A hyperactive mutation of *PKC1*, a central downstream component of CWI pathway, causes a cell fusion defect. Moreover, the CWI pathway is activated by pheromone-induced morphogenesis. The five transmembrane protein sensors (Wsc1-3p, Mid2p, and Mtl1p) of the

CWI signaling cascade have been suggested to act as mechanosensors. We hypothesize that cell-cell contact relieves CWI signaling to allow cell wall degradation. Loss of *MID2* causes "mating-induced death" after exposure to pheromone. We find that the mating-induced death is due to localized loss of cell wall and plasma membrane integrity. Mutations in several genes required for cell fusion (*FUS1, FUS2, RVS161, CDC42*), but not nuclear fusion (*KAR5*) suppress *mid2*, suggesting that the mating-induced death is due to unregulated cell fusion. Fus2p functions late in mating to regulate cell wall removal and loss of Fus2p causes a block in cell fusion. Deletion of *WSC1* or *MID2* partially suppresses the cell fusion defect of *fus2*Δ,*fus1*Δ, *rvs161-10* and *cdc42-138*. These data suggest a role for the CWI pathway in regulating cell wall degradation during yeast mating. Interestingly, loss of *WSC1* specifically leads to zygote/diploid cell death. Although *fus2*Δ suppresses the phenotype of *mid2*Δ, it does not suppress the defect of *wsc1*Δ. Taken together these data suggest distinct roles for *WSC1* and *MID2* in cell fusion and diploid cell wall integrity.

Y496 Flipping the Switch": ROS-induced degradation of Med13 by SCF^{Grr1} mediates mitochondrial fragmentation and cell death. *D. Stieg*[1], S. Willis[1], J. Scuorzo[2], M. Song[2], K. Cooper[1]. 1) Dept. of Molecular Biology, Rowan SOM, Stratford, NJ; 2) Dept. of Medicine, Rowan SOM, Stratford, NJ.

In response to stress, the yeast[1] and mammalian[2] cyclin C translocate from the nucleus to the cytoplasm where it associates with the GTPase Drp1/Dnm1 to drive mitochondrial fragmentation and apoptosis. Therefore, the decision to release cyclin C represents a key life or death rubicon. In unstressed cells, the cyclin C-Cdk8 kinase regulates transcription by associating with the Mediator of RNA polymerase II. We previously reported that that the Mediator component Med13 anchors cyclin C in the nucleus[3]. Loss of Med13 function leads to constitutive cytoplasmic localization of cyclin C resulting in fragmented mitochondria, hypersensitivity to stress and mitochondrial dysfunction due to loss of mtDNA. Recently we showed that this molecular switch operates in a two step process. First, efficient cyclin C nuclear release requires its ROS-induced phosphorylation by the MAP kinase Slt2[4] in a carboxyl terminal region of cyclin C that includes a putative Med13 interaction site. Also, exposure of cells to high ROS damage activates the AMP kinase Snf1 that promotes cyclin C release through an indirect mechanism. The second step involves ROS-induced Med13 destruction by the SCF^{Grr1} ubiquitin ligase. Med13 associates with Grr1 in two-hybrid assays and SCF mediated degradation of Med13 requires active cyclin C-Cdk8. Taken together, these results indicate that the cell gauges damage severity by sequential activation of multiple signaling pathways. These results are consistent with a model in which cyclin C phosphorylation permits its disassociation from Med13 and that Med13 destruction allows full cyclin C release and prevents reaccumulation of the cyclin in the nucleus.

Y497 Protein sequestration after genotoxic stress regulates splicing. *Peter Stirling*[1,3], Annie Tam[1], Christopher Hughes[2], Gregg Morin[2,3], Veena Mathew[1]. 1) Terry Fox Laboratory British Columbia Cancer Agency, Vancouver, BC, CA; 2) Genome Sciences British Columbia Cancer Agency, Vancouver, BC, CA; 3) Department of Medical Genetics University of British Columbia, Vancouver, BC, CA.

The cellular response to stress is coupled to an array of dynamic events. In response to DNA damaging stresses; DNA repair proteins move to sites of damage, the transcription machinery is modified, RNAs are organized into stress granules and P-bodies and proteins can be sequestered in aggregates. These dynamic changes collaborate to repair DNA, and alter the transcriptome and proteome to enable stress recovery. We identified an unexpected relocalization of the splicing factor Hsh155 to both intranuclear (INQ) and cytoplasmic (CytoQ) sites of protein quality control (PQC) upon exposure to the genotoxin methyl methanesulfonate (MMS). Hsh155 localization to PQC sites is promoted by molecular chaperones Hsp42 and Btn2 and is suppressed by the action of the Hsp104 disaggregase and the INQ component Apj1. Hsh155 protein is stable after MMS treatment and, like other aggregates, new translation is required for Hsh155 relocalization. Functionally, Hsh155 localization to PQC sites is correlated with a precipitous drop in splicing efficiency. To extend previous microarray studies, we conducted whole proteome analysis after MMS treatment and observed specific depletion of ribosomal proteins, whose mRNA products together command the largest need for spliceosomal function in yeast. We propose a model in which sequestration of Hsh155 is required to regulate splicing activity when ribosomal protein gene synthesis is arrested by genotoxic stress. These analyses reveal a novel function of PQC structures and highlight protein sequestration as a potential tool in the dynamic cellular control of the transcriptome and proteome under stress.

Y498 The DNA damage checkpoint targets the exoribonuclease, Xrn1, in response to damage. *J. P. Lao*[1], K. M. Ulrich[1], A. A. Vashisht[2], J. R. Johnson[1], N. J. Krogan[1], J. A. Wohlschlegel[2], D. P. Toczyski[1]. 1) University of California, San Francisco, San Francisco, CA; 2) University of California, Los Angeles, Los Angeles, CA.

Cells incur DNA damage from both endogenous cellular metabolism and exogenous sources. The highly conserved DNA damage response (DDR) pathway monitors the genomic integrity of the cell and protects against genotoxic stresses. Genome instability is a common characteristic of cancer cells, and components of the DDR machinery are often mutated in cancer. In *Saccharomyces cerevisiae*, DNA damage activates the sensor kinases, Mec1 and Tel1 (ATR and ATM in human, respectively). The response is further amplified by activation of the effector kinase, Rad53, to regulate a variety of cellular processes, including cell cycle progression, DNA damage repair, chromatin remodeling, and transcription.

To improve our understanding of the global response to DNA damage, we sought to identify targets of Rad53 using a mass spectrometry-based phosphoproteomic screen in a strain deleted for phosphatases known to counteract checkpoint kinases. Of the top 40 hits, we found that 17 display DNA damage-dependent mobility shifts on SDS-PAGE gels and determined that Rad53 phosphorylates 22 out of the 40 hits by *in vitro* kinase assay. Many of the hits are proteins that are involved in RNA metabolism. In particular, we are following up on Xrn1, a highly conserved 5' exoribonuclease, which functions primarily in mRNA decay. Xrn1 is modified upon DNA damage in a checkpoint-dependent

manner and is directly phosphorylated by Rad53 *in vitro*. We used SILAC to identify proteins that interact with Xrn1 in a *RAD53*-dependent manner. Preliminary data suggests that the association of Lsm1 and Lsm3 with Xrn1 is reduced in a *rad53Δ*. In addition, we have found that at least one member of the decapping complex rescues the strong damage sensitivity of an *xrn1*Δ. We are currently conducting an unbiased screen to identify other suppressors of this mutant to determine the pathway relevant to its damage sensitivity. We hypothesize that the DDR regulates mRNA turnover by targeting Xrn1 in response to damage.

Y499 The lysine acetyltransferase NuA4 regulates glucose-deprived stress granule formation through cellular acetyl-CoA levels. *S. Huard*[1,2], M. Rollins[1,2], A. Morettin[3], J. Takuski[1,2], M. Fullerton[2], J. Côté[3], K. Baetz[1,2]. 1) Ottawa Institute of Systems Biology; 2) Department of Biochemistry, Microbiology and Immunology, University of Ottawa, Ottawa, Canada; 3) Department of Cellular and Molecular Medicine, University of Ottawa, Ottawa, Canada.

Eukaryotic cells form cytoplasmic RNA-protein aggregates or stress granules (SGs) under a variety of stress conditions and their formation is associated with both neurodegenerative diseases and cancer. For each stress condition distinct stress-activated signaling pathways regulate SG formation, however the molecular details of these pathways remain largely unknown. We have determined that the *Saccharomyces cerevisiae* lysine acetyltransferase complex NuA4 is required for SG formation specifically upon glucose deprivation but no other stresses tested. Similarly the Tip60 complex, the human homolog of the yeast NuA4 complex, is also required for SG formation in human cell lines indicating that NuA4/Tip60 is a conserved signaling pathway regulating SG dynamics. Surprisingly we found that the impact of NuA4 on glucose-deprived SG formation is not through the regulation of core SG protein levels, or inhibition of translation, rather it is through regulation of acetyl-CoA levels. Cells in which the Acetyl-CoA synthetase *ACS1* is deleted, which have decreased acetyl-CoA levels, display increased SG formation upon glucose deprivation. In agreement, cells in which the Acetyl-CoA carboxylase *ACC1* is mutated or in cells exogenous treated with acetate, which have increased acetyl-CoA levels, glucose deprived SG formation is suppressed. Like NuA4, acetyl-CoA levels appear to only contribute to SG formation upon glucose deprivation. Remarkably we determined that mutants of NuA4 have increased acetyl-CoA levels, decreased Acc1 activity and mislocalized Acc1-GFP. Our observations indicate that NuA4 is regulating acetyl-CoA levels through Acc1 and that acetyl-CoA is acting as a signaling rheostat for SG formation upon glucose deprivation.

Y500 The Quick and the Dead: Single-cell Demography at the Yeast Thermal Limit. *P. M. Magwene*, C. S. Maxwell. Duke University, Durham, NC.

What factors limit where a microbial species grows and thrives? Population growth rate is a function of two demographic parameters – rates of birth and death. Analyzing changes in birth and death rates in response to environmental stress can help to identify physiological constraints that limit microbial niches; however measuring them in microbial populations is challenging. In order to overcome this obstacle, we developed a novel cellular mark-release-recapture technique called "TrackScar" that enables single-cell measurement of age-structured birth and death rates in budding yeast. We used this method to study the demographic and physiological factors that limit population growth during heat stress in a genetically diverse panel of *Saccharomyces cerevisiae* strains. We find that the average population growth rate during stress is often a poor predictor of the behavior of individual cells because of heterogeneity in fecundity. Age-structured mortality is one cause of this heterogeneity and is also highly variable across strains. Some genetic backgrounds senesce prematurely during heat stress, while others show the opposite pattern, with elevated rates of early life mortality. Age structuring of birth and death rates points to potential genotype-by-environment effects on processes that regulate asymmetric cell division; consistent with this we find that a mitochondrial inheritance defect explains the early life mortality phenotype of one of the strains we studied. This study demonstrates that characterizing the behavior of individual cells is critical to understanding the physiology of microbes and highlights how the interplay of cellular physiology, genetic variation, and environment influences where microbial populations survive and flourish.

Y501 The RSC complex functions to maintain ploidy in *Saccharomyces cerevisiae*. *T. L. Sing*[1,2], M. P. Hung[1,2], S. Ohnuki[3], J. Ou[1,2], B. J. San Luis[2,4], M. Costanzo[2,4], C. Boone[2,4], Y. Ohya[3], G. W. Brown[1,2]. 1) Department of Biochemistry, University of Toronto, Toronto, Ontario, Canada; 2) Donnelly Centre for Cellular and Biomolecular Research, Toronto, Ontario, Canada; 3) Department of Integrated Biosciences, University of Tokyo, Tokyo, Japan; 4) Department of Molecular Genetics, University of Toronto, Ontario, Canada.

Ploidy is tightly regulated in eukaryotic cells, and is critical for cell function and survival. Cells must coordinate multiple pathways to ensure replicated DNA is segregated both accurately and in a timely fashion to prevent changes in chromosome number. Several cellular processes have been implicated in ploidy maintenance, including spindle pole body (SPB) duplication, mitotic spindle formation and kinetochore attachment.

We have discovered an unanticipated role for 6 of 7 non-essential subunits of the RSC (Remodels the Structure of Chromatin) complex in ploidy maintenance. Using flow cytometry, we demonstrated that deletion of *RSC1, RSC2, RSC30, LDB7, NPL6,* or *HTL1,* but not *RTT102,* causes a rapid transition from haploid to diploid DNA content following germination of haploid mutant spores. Unlike normal diploids that arise from mating, *rscΔ* mutant diploids retained the ability to mate, indicating that diploidization is the result of autopolyploidization rather than mating-type switching. Interestingly, morphological analysis revealed that diploidized *rscΔ* mutants have an elongated bud phenotype, which makes them distinct from wild type diploids.

Microscopic analysis revealed that *rscΔ* mutants do indeed have defects in SPB duplication and maturation that explain the increase-in-ploidy phenotype. Using RNA sequencing, we showed that these defects were not due to obvious changes in transcript levels in the *rscΔ* mutants. Therefore, we performed synthetic genetic array (SGA) analysis, which implicated the RSC complex in regulating proteins important for inserting newly synthesized SPBs into the nuclear envelope. Surprisingly, we were unable to detect physical interactions between the RSC

complex and SPBs by yeast 2-hybrid (Y2H) or bimolecular fluorescence complementation (BiFC). Instead, evidence has lead us to a model where the RSC complex facilitates nuclear pore complex (NPC) stability and/or localization, which is necessary for proper SPB insertion.

Understanding how the RSC complex regulates ploidy will contribute to an integrated view of how multiple pathways converge to maintain the haploid state and propagate it from one generation to the next.

Y502 Yeast Genetics Meeting Lifetime Achievement Award. *J. R. Broach*. Penn State College of Medicine, Hershey, PA.

Y503 A comprehensive genotype-fitness map of adaptation-driving mutations in yeast. *Barbara Dunn*[1], Sandeep Venkataram[2], Yuping Li[2], Atish Agarwala[3], Jessica Chang[1], Emily Ebel[2], Kerry Geiler- Samerotte[2], Lucas Herissant[1], Sasha Levy[4], Jamie Blundell[4,5], Daniel Fisher[5], Gavin Sherlock[1], Dmitri Petrov[2]. 1) Dept of Genetics, Stanford Univ, Stanford, CA, USA; 2) Dept of Biology, Stanford Univ, Stanford, CA, USA; 3) Dept of Physics, Stanford Univ, Stanford, CA, USA; 4) Dept of Biochem & Cell Biol, Stony Brook Univ, Stony Brook, NY, USA; 5) Dept of Applied Physics, Stanford Univ, Stanford, CA, USA.

Adaptive evolution is a major driving force behind the phenotypic variation observed in nature, and recent advances in high-throughput sequencing now make possible the deep sampling of adaptive events during the course of a controlled evolution experiment. We developed a DNA barcoding approach to track over time the changes in population frequency of ~500,000 otherwise identical clones of the budding yeast *Saccharomyces cerevisiae*, and have monitored these clonal "fitness trajectories" for up to ~250 generations under a glucose limited regime (Levy, Blundell, et al., Nature, 2015). In this study, we have isolated 4,800 independently evolved clones from the 88 generation timepoint of the barcoded evolution, when most adaptive clones are likely to contain only a single adaptive mutation, and have developed an assay to assign fitness values to each individual clone in a highly parallel manner. This allows us to determine if the clone is adaptive (carries a presumptive adaptive mutation) or non-adaptive (carries either neutral or no mutations). We performed whole genome sequencing on hundreds of individual known adaptive clones, as well as many neutral clones as controls, and have identified many of the adaptive mutations that have independently arisen in these evolutions. There are two major classes of adaptive mutations: (1) self-diploidization, conferring an average fitness benefit of ~3%, and (2) mutations in the nutrient-responsive Ras/PKA and TOR/Sch9 pathways, conferring fitness benefits of ~5% to ~15%, and ~5% to 10%, respectively. Our large sample size and precision of measurement have allowed us to observe that the differential fitness benefits conferred by these mutations are dependent on the affected pathway, the individual gene, and even the type of mutation within a single gene. Additionally, we observe consistent differential fitness advantages for clones carrying mutations in paralogous genes; for example, *IRA1* mutations confer on average a higher fitness advantage than do *IRA2* mutations, while *GPB2* mutations confer higher fitness benefits than *GPB1* mutations. In summary, we have been able to link the specific molecular targets of adaptation to their fitness effects and build a comprehensive genotype-fitness map of the adaptive mutations that drove the initial evolutionary process in this system.

Y504 Extrachromosomal Circular DNA – A Key Player in Creation of Copy Number Variation? *Henrk D. Møller*[1], Tobias Mourier[2], Lance Parsons[3], Birgitte Regenberg[1]. 1) Department of Biology, University of Copenhagen, Copenhagen, Denmark; 2) Natural History Museum of Denmark, University of Copenhagen, Copenhagen, Denmark; 3) Lewis-Sigler Institute for Integrative Genomics, Princeton University, United States.

Numerous human cancer types are caused by copy-number variations (CNVs) of proto-oncogenes. Yet, detecting chromosomal CNVs before they reach establishment in large cell populations is a major challenge. By screening for a potential deletion-byproduct of CNVs, the so-called extrachromosomal circular DNA (eccDNA), we reasoned that we might elucidate some of the early ongoing processes in genomic rearrangements.

To explore the existence of circular DNA in eukaryotes we have developed a highly-sensitive eccDNA purification method, Circle-Seq, that relies on removal of linear DNA and next-generation sequencing of circular DNA. We reveal that CNVs, in the form of eccDNAs, are common in the budding yeast *Saccharomyces cerevisiae.* More than a thousand different eccDNAs larger than 1 kb were recorded in the S288c strain background increasing the known number of eccDNA more than a hundred fold. A number of eccDNAs were found repeatedly in S288c and in the CEN.PK strain background, suggesting conserved hotspots for DNA circularization, e.g. at ribosomal RNA genes, glucose transporter genes *HXT6*, *HXT7,* metallothionein genes *CUP1-1*, *CUP1-2*, Ty-retrotranposons and Y'-telomeric genes. Recording of *HXT6-HXT7* geneotypes indicated selection for [$HXT6/7^{circles}$] in continued yeast cultures under glucose-limitation and [$HXT6/7^{circles}$] also appeared to serve as intermediates of chromosomal amplifications. Sequenced recombination junctions of circular Ty-elements revealed that retrotransposons can form by recombination both within the genome and during the classical retrotranspositional life cycle.

Our results suggest that eccDNAs are frequent genomic rearrangements in *S. cerevisiae* that lead to deletions and transient gene amplifications. Consequently, *S. cerevisiae* is a useful model organism for studying the molecular basis and evolutionary consequences of eccDNA.

Y505 Deciphering common principles governing gene replaceability in yeast. *Aashiq H. Kachroo*[1], Jon M. Laurent[1], Azat Akhmetov[1], Edward M. Marcotte[1,2,3]. 1) Center for Systems and Synthetic Biology, Institute for Cellular and Molecular Biology, University of Texas at Austin, Austin, TX 78712, USA; 2) Center for Computational Biology and Bioinformatics, University of Texas at Austin, Austin, TX 78712, USA; 3) Department of Molecular Biosciences, University of Texas at Austin, Austin, TX 78712, USA.

Owing to common ancestry, organisms share genes across vast evolutionary distances, with many eukaryotic genes shared among humans, yeast, plants, and even bacteria. "Swapping" such orthologous genes between species gives a simple, reasonably high-throughput, method for

testing conserved functions and learning principles of replaceability. Recently, we showed that several hundred genes in yeast can be "humanized", in the process learning some of the rules that govern functional replaceability. Notably, we found that replaceability is determined at the level of gene modules, such that genes in the same pathway or complex are often either largely replaceable or not (Kachroo *et al*. (2015) *Science*, 348:921-925).

However, it is unknown if these trends are truly general in nature and apply equally well to other species. To learn general rules of replaceability, we have now replaced (one gene at a time) a large set of budding yeast (*S. cerevisiae*) genes with their orthologs from bacteria (*E. coli*), and to a lesser extent, from plants (*A. thaliana*). We find that a large proportion (roughly half) of the bacterial or plant genes tested can successfully replace their yeast orthologs and complement an otherwise lethal loss of an essential yeast gene. As with our systematic tests of yeast humanization, we observe genes in the same pathway and complex to be similarly replaceable or not. Strikingly, individual genes of the yeast heme biosynthesis pathway are almost entirely replaceable by their orthologs from *E. coli*, plants, or humans, indicating that this ancient pathway has remained functionally intact and largely unaltered—at least in terms of its critical, enzymatic functionality—since the divergence of the ancestors of modern eubacteria and eukaryotes. Finally, we'll describe our extensions of this work, testing for the effects of mitochondrial localization, and using CRISPR-based integration of the donor genes directly into the yeast chromosomes, to more finely control the human/plant/bacterial-ized genes' expression patterns.

Y506 The 1002 yeast genomes project. *J. Schacherer*[1], J. Peter[1], M. De Chiara[2], D. Pflieger[1], JX. Yue[2], A. Bergstrom[2], A. Sigwalt[1], A. Llored[2], K. Freel[1], S. Engelen[3], A. Lemainque[3], P. Wincker[3], A. Friedrich[1], G. Liti[2]. 1) University of Strasbourg, Strasbourg, FR; 2) Institute of Research on Cancer and Ageing, Nice, FR; 3) Institut de Génomique - Genoscope, Evry, FR.

Genome-wide investigation of the patterns of polymorphism in a large sample of individuals is the first step to assess the relationship between genotype and phenotype within a species. To date, yeast population genomics only focused on a limited number of isolates. In this context, we initiated a project with the goal of describing whole-genome sequence variation in more than 1,000 natural *S. cerevisiae* genomes, avoiding monosporic strains (http://1002genomes.u-strasbg.fr/). Genomes were sequenced using an Illumina HiSeq 100-bp paired-end strategy that yielded a 200-fold coverage on average. Sequenced strains were selected to include as much diversity as possible in terms of global locations (including Australia, Europe, Russia, Vietnam and South Africa), as well as ecological sources (such as dairy products, trees, insects, flowers, fruit and wine). In addition, almost 1,000 were phenotyped on different conditions impacting various physiological and cellular responses, including different carbon sources, membrane and protein stability, signal transduction, sterol biosynthesis, transcription, translation, as well as osmotic and oxidative stress. In total, we analyzed 34,740 measurements for 36 traits.

Due to the broad diversity of isolates selected, this population genomic dataset revealed an accurate picture of the genomic variation (*i.e.* ploidy, aneuploidy, copy number and gene content variation). We found that genomic variations are correlated with the ecological origin of the isolates but also have a direct and general impact on fitness. Concerning the single nucleotide polymorphisms, a total of 58,912,916 high-quality SNPs were detected across the 1,011 genomes, which are distributed over 1,625,809 polymorphic positions. The frequency spectrum of the observed polymorphisms is highly skewed towards an excess of low-frequency alleles. The heterozygosity level also depends on the ecological origin and losses of heterozygosity are considerable in *S. cerevisiae*, with an average of 21 regions covering ~5 Mb per heterozygous genome.

Overall, our study led to a comprehensive view of the multiple genome evolution patterns across subpopulations within the *S. cerevisiae* species. Furthermore, because we performed extensive phenotyping, the high SNPs density allowed us to perform genome-wide association studies. This dataset led to the identification of a large set of functional polymorphisms that underlie phenotypic variation.

Y507 Integrative Analysis of the Variation in the Regulatory Network Among Strains of Yeast. *R. Srivas*[1], B. Dunn[1], T. Kawli[1], L. Jiang[1], E. Li[1], K. Choe[2], J. Gallagher[3], M. Snyder[1]. 1) Stanford University, Stanford, CA; 2) N. Carolina State Univ, Raleigh, NC; 3) West Virginia University, Morgantown, WV.

Regulation of gene expression is a complex affair involving changes in chromatin structure and histone modifications, as well as coordinated action amongst trans-acting transcription factors (TF). To date the extent to which variation in these regulatory mechanisms can influence gene expression, and thus contribute to phenotypic variation, has been limited to examining each regulatory layer in isolation or in the case of TFs, just one or two factors. Here, we present a unified analysis of the regulatory network in five diverse strains of the yeast S. cerevisiae, including genome-wide measurements of the binding locations of 52 TFs (~25% of all TFs), chromatin accessibility and four histone modifications. We observed a broad-range (between 0.1 and 0.75) in the fraction of binding sites different between strains across all TFs, with highly conserved and essential TFs displaying significantly lower binding variability. Variable binding regions and chromatin states were enriched for single-nucleotide variants, and coordinated changes across multiple regulatory layers, in contrast to any single data type, were highly correlated with differences in gene expression. Our data provide a unique resource to examine the impact of sequence-level variation across multiple layers of gene regulation.

Y508 Comparative translatomics reveal a conserved class of noncanonical uORFs in yeast. *Joel McManus*[1], Armaghan Naik[1], Pieter Spealman[1], Gemma May[1], Scott Kuersten[2], Lindsay Freeberg[2], Robert Murphy[1]. 1) Carnegie Mellon University, Pittsburgh, PA; 2) Illumina, Inc., Madison WI.

Upstream Open Reading Frames (uORFs) have emerged as major *cis*-acting elements involved in regulating mRNA turnover and translation (Wethmar, 2014; Ingolia 2014). We and others have found that genetic variation in putative uORFs has contributed to variation in translation in yeast (McManus et al., 2014), mice (Hou et al., 2014), and humans (Cenik et al., 2015). Furthermore, mutations in uORFs are associated with

human disease (Calvo et al., 2009). Functional uORFs can be challenging to identify, as they often reside in alternative regions of mRNA transcript leaders, and have limited sequence conservation. Curiously, recent work has uncovered a large number of uORFs initiating with non-AUG start codons, with functions implicated in development and stress responses (Ingolia et al., 2009; Brar et al., 2011). While the catalog of such noncanonical uORFs continues to increase, little is known about their functions and evolution.

To study the evolution of uORFs, we used targeted RNA-sequencing to map transcript start and end sites in all five *Saccharomyces sensu stricto* yeast species. Comparison of UTR lengths in these species revealed that genes involved in translation and glycolysis have highly conserved transcription start and end sites, many that have remained entirely stable over 15 million years. Many genes contain conserved alternative transcription start and end sites, suggesting transcriptional regulation of UTR sequences. As expected from prior work, "AUG" triplets are depleted from 5' UTRs in each species. Surprisingly, we find that "UUG" is the most enriched triplet in 5' UTRs, suggesting selective pressure to maintain uORFs initiating with this codon. To investigate the importance of UUG enrichment, we searched 5' UTRs for functional uORFs using ribosome profiling data from *S. cerevisiae*, *S. paradoxus*, and *S. uvarum* using a novel machine learning algorithm (uORF-seeker). This analysis identified both conserved and species-specific AUG- and UUG-uORFs in hundreds of orthologous 5' UTRs. Interestingly, conserved UUG uORFs are highly enriched in genes involved in regulating cellular growth during stress. Our results show that UUG- and AUG-uORFs have similar rates of conservation and implicate UUG-uORFs in repressing cellular growth genes in response to stress.

Y509 Mating-type switching in the methylotrophic yeast *Hansenula polymorpha* is regulated by yeast mating and differentiation pathways. *Sara Hanson*, Kevin Byrne, Kenneth Wolfe. Conway Institute and School of Medicine & Medical Science, University College Dublin, Dublin, IE.

Changes in environmental conditions can result in remarkable variations in the expression of phenotypes and the induction of differentiation processes. An important factor distinguishing *Saccharomyces cerevisiae* from many other yeast species is the role of environmental signals in the induction of sexual processes. Natural isolates of *S. cerevisiae* are primarily diploid (diplontic lifestyle). An environmental cue (nitrogen starvation) is required to induce them to sporulate, but the resulting haploids can then go through mating-type switching and mating without any additional environmental input. In contrast, many other yeasts such as the methylotrophic species *Hansenula polymorpha* are primarily haploid (haplontic lifestyle). In these species mating-type switching, mating, and sporulation are coordinately induced by nitrogen limitation. Mating-type switching in *H. polymorpha* occurs through a two-locus chromosomal inversion mechanism that is ancestral to the well-characterized three-locus MAT/HML/HMR mechanism in *S. cerevisiae*. Although nitrogen limitation has been identified as the primary nutritional signal, the molecular pathway from this signal to mating-type switching in *H. polymorpha* is unknown. We surveyed *H. polymorpha* strains and found one strain that is unable to switch mating-types. This strain was crossed with a switching strain and bulk segregant analysis revealed a frameshift in the transcription factor *EFG1*, homolog of *S. cerevisiae PHD1* and *SOK2*, as the causative mutation. Although *EFG1* has a well-characterized role as a key regulator of filamentous growth and the white-opaque phenotypic switch in *Candida albicans*, it was not previously known to have a direct role in mating in any species. Through functional genetics and mRNA-seq analysis, we have found that *EFG1* is part of a transcriptional network that integrates components of the *S. cerevisiae* mating and *C. albicans* differentiation pathways to control mating-type switching and mating responses in *H. polymorpha*.

Y510 The 3D organization of the diploid *Saccharomyces* genome. *Seungsoo Kim*[1], Ivan Liachko[1], Gurkan Yardimci[1], Kate Cook[1], William Noble[1], Maitreya Dunham[1], Jay Shendure[1,2]. 1) University of Washington, Seattle, WA; 2) Howard Hughes Medical Institute.

The genome is packed into the nucleus in a highly organized manner, and this organization has consequences for transcriptional regulation, DNA break repair, and other nuclear processes. In *Saccharomyces* budding yeasts, the genome is positioned in a Rabl orientation throughout the cell cycle, with centromeres attached to the spindle pole, the nucleolus opposite to the spindle pole, and telomeres at the nuclear periphery. Although various studies have suggested additional features of *Saccharomyces* budding yeast nuclear organization, such as clustering of tRNA genes and origins of replication, genome-wide chromatin conformation capture (Hi-C) data from haploids lack evidence of long-range interactions driven by DNA sequence and can largely be explained by simple polymer models simulating a Rabl configuration. Further, although FISH- and recombination-based studies have suggested mitotic pairing of homologous chromosomes in diploid yeast, whether mitotic pairing occurs remains controversial and has not been interrogated in a genome-wide manner. To systematically uncover the 3D organization of the diploid budding yeast genome, we performed Hi-C on interspecific hybrids of *S. cerevisiae*, *S. paradoxus*, and *S. uvarum* during exponential growth and stationary phase. Here, we report that the organization of diploid *Saccharomyces* genomes, unlike those of haploids, substantially deviates from the simple polymer model. First, the homologous chromosomes carrying the rDNA arrays interact preferentially, even at their centromeres. Although preferential pairing of sequences near the rDNA arrays could be predicted by simple polymer models, the pairing of the centromeres is less easily explained. Second and even more surprisingly, we find that specific homologous sequences on chromosome 13 interact with each other, only in stationary phase. A deletion of one copy of this region in *S. cerevisiae* x *S. uvarum* eliminated the interaction, and sequentially smaller deletions allowed us to narrow down the source of the interaction to a ~1 kb intergenic region. Unlike previously reported interactions between genes relocated to the nuclear pore complex upon induction, this novel interchromosomal interaction appears to be repressive, as the region is bound by stress-induced transcriptional repressor Xbp1 and is flanked by genes repressed during stationary phase. Finally, we show that in both hybrids of diverged *S. cerevisiae* strains and *S. cerevisiae* x *S. paradoxus* hybrids, interactions between homologous regions are subtly but clearly enriched even after controlling for their distances from centromeres; we conclude that in diploid budding yeasts, mitotic pairing of homologous chromosomes occurs genome-wide.

Y511 A global yeast genetic network maps cellular function. *M. Costanzo*[1], B. VanderSluis[2], E. Koch[2], A. Baryshnikova[3], C. Pons[2], G. Tan[1], C. Myers[2], B. Andrews[1], C. Boone[1]. 1) Univ Toronto, Toronto, ON, CA; 2) Univ Minnesota, Minneapolis, MN; 3) Princeton Univ, Princeton, NJ.

We generated a global genetic interaction network for *Saccharomyces cerevisiae*, constructing 23.4 million double mutants, identifying ~620,000 negative and ~390,000 positive genetic interactions. Our network maps genetic interactions for essential gene pairs, highlighting essential genes as densely connected hubs. Genetic interaction profiles enabled assembly of a hierarchical model of cell function, including modules corresponding to protein complexes and pathways, biological processes, and cellular compartments. Negative interactions connected functionally related genes, mapped core bioprocesses, and identified multifunctional pleiotropic genes. Positive interactions often mapped general regulatory connections among gene pairs, rather than shared functionality. The global network illustrates how sets of genetic interactions occur within and between genes encoding complexes and pathways and how this topology can be exploited to explore genetic interactions underlying human disease.

Y512 A programmable sensor for protein solubility in yeast uncovers ecological prion-switching factors. *G. A. Newby*[1,2], S. Kiriakov[3], C. Kayatekin[1], M. Khalil[3], S. Lindquist[1,2]. 1) Whitehead Institute, Cambridge, MA; 2) MIT, Cambridge, MA; 3) Boston University, Boston, MA.

Protein aggregation is frequently associated with disease and dysfunction, but is also vital to many aspects of normal biology, from meiosis to memory. Unfortunately, protein aggregates are notoriously difficult to compare and quantify. We have developed a synthetic sensor for protein aggregation in yeast by coupling the solubility of a given protein to a fluorescent or enzymatic reporter. This modular platform is amenable to quantitative, high throughput screening and selection, or can be used to measure individual live cells with microscopy. We applied the tool first to study yeast prions, which are heritable, self-templating protein conformations that confer different phenotypes depending on their conformational state. Screening a pool of random mutations in prion genes, we identified dominant mutations in yeast prions that solubilize and cure the endogenous, wild type prion aggregate. One of these mutations is already harbored by rare, wild strains of yeast. We predict that this strain would be immune to a yeast prion and would cure the prions of its mating partners. We then conducted screens of environmental stresses and a natural product library to uncover drugs and conditions that affect prion switching. We identified a number of drugs and conditions that yeast may encounter in their natural habitat and are active in switching their prion state. Encountering these factors would cause a heritable prion switch that would be 'remembered' by the population for generations to come, significantly altering their phenotype. Our technology is also applicable to the analysis of non-prion aggregates. We have utilized the technique to measure sequestration of endogenous cellular proteins by aggregation-prone human disease proteins *in vivo*. We used this to learn about the sequence elements that influence the interaction of the disease aggregate with endogenous proteins. This technique unlocks previously-inaccessible questions in the investigation of protein aggregation.

Y513 Identifying synthetic cytotoxic genetic interactions with DNA damaging therapeutic agents. *Xuesong Li*, Nigel J. O'Neil, Phil Hieter. The University of British Columbia, Vancouver, B.C., CA.

Many tumors contain mutations that affect the DNA Damage Response (DDR) and genome stability. These mutations differentiate tumour cells from normal surrounding tissue and could be targeted by therapeutics that are based on negative genetic interactions with these mutations. While some genetic interactions result in synthetic lethality, other genetic interactions may increase the sensitivity of tumor cells to DNA damaging therapeutic agents, resulting in a class of conditional synthetic lethality we call Synthetic Cytotoxicity (SC). To identify SC interactions, we are screening yeast DDR mutants for SC interactions with several different DNA damaging agents using both a genome-wide array of non-essential mutants and a curated mini-array of mutants enriched for DDR genes. To date, we have screened mutations affecting the DNA damage checkpoint Tel1 (the yeast ATM ortholog) and the four core components of the non-homologous end joining (NHEJ) machinery: Yku70/Yku80 (DNA end–binding Ku heterodimer) and Dnl4/Lif1 (DNA ligase IV) for SC with four different DNA damaging agents: Bleomycin (radio-mimetic), Camptothecin (TopI inhibitor), Cisplatin (interstrand crosslinker), and MMS (alkylating agent). We characterized and investigated the biology of several strong SC interactions and tested for evolutionary conservation in *C. elegans*. Our SC interaction network of DDR pathways will help interpret the complex networks that maintain genome stability after exposure to DNA damaging therapeutic agents, and will provide a valuable resource for the rational design of personalized therapy based on tumour genotypes.

Y514 High throughput protein-protein interaction sequencing using iSeq. *Z. Liu*[1,2], U. Schlecht[3], JR Blundell[1,2,4], R. Bennett[1,2], RW Davis[3], RP St. Onge[3], SF Levy[1,2]. 1) Laufer Center for Physical and Quantitative Biology, Stony Brook University, Stony Brook, NY; 2) Department of Biochemistry and Cellular Biology, Stony Brook University, Stony Brook, NY; 3) Stanford Genome Technology Center, Department of Biochemistry, Stanford University, Palo Alto, CA; 4) Department of Applied Physics, Stanford University, Stanford, CA.

In *Saccharomyces cerevisiae*, several large-scale efforts have systematically catalogued the protein-protein interactions in a single environment. However, little is known about how the protein interactome changes across genetic or environmental perturbations. Current technologies, which assay one PPI at a time, are too low throughput to make it practical to study these protein interactome dynamics. Here, we develop a massively parallel protein-protein **i**nteraction **Seq**uencing platform (iSeq) using a novel double barcoding system in conjunction with the murine dihydrofolate reductase-based protein-fragment complementation assay (PCA). Random barcodes are inserted into yeast and are mated to existing PCA strains. Mating of barcoded haploid PCA pools and translocation of barcodes *in vivo* and *en masse* yields diploid PCA strains, each with a double barcode representing a specific PPI. In a pilot study, we generated a pool of 2500 strains that represent 100 PPIs, each tagged with 25 unique double barcodes. Growth of this cell pool and sequencing of double barcodes yields an accurate fitness measurement of each double barcode in the pool, which can be translated to an interaction score for each pairwise protein combination. We find that PPI interaction scores using iSeq are highly reproducible across both double barcodes and growth replicates. Under standard growth

conditions, our system detects most previously-reported PPIs. Additionally, we identify many additional putative PPIs with weaker interaction scores. By growing this pool in four different conditions, we identify several dynamic PPIs that reproducibly change in strength across environments. Verification of new and dynamic PPIs is ongoing. Finally, we demonstrate that the iSeq platform is capable of generating and assaying millions of PPIs in parallel. Current efforts are focused on building larger iSeq yeast pools to perform genome-scale dynamic PPI studies.

Y515 Scalable tools for the quantitative analysis of chemical-genetic interactions from sequencing-based chemical-genetic interaction screens. *S. W. Simpkins*[1], J. Nelson[1], R. Deshpande[1], S. Li[2], J. S. Piotrowski[3], C. M. Boone[4], C. L. Myers[1]. 1) Computer Science and Engineering, Univ. of Minnesota, Minneapolis, MN, USA; 2) Center for Sustainable Resource Science, RIKEN, Saitama, Japan; 3) Yumanity Therapeutics, MA, USA; 4) Donnelly Centre for Cellular and Biomolecular Research, Univ. of Toronto, ON, Canada.

Driven by the vision of high-throughput, unbiased, functional chemical screens and enabled by the functional genomics resources available for *S. cerevisiae*, it is now possible to screen tens of thousands of compounds for chemical-genetic interactions in just a few months' time. To fully take advantage of this substantial increase in throughput, scalable computational tools must be developed to assist in both generating and interpreting chemical-genetic interaction profiles from these data. To this end, we developed two computational tools, BEAN-counter and CG-TARGET, the former to convert raw barcode sequencing data into chemical-genetic interaction profiles and the latter to derive actionable mode-of-action predictions from chemical-genetic interaction profiles.

BEAN-counter provides a complete toolset for processing multiplexed sequencing data from barcoded mutant pools into chemical-genetic interaction profiles. The pipeline implements several quality control and normalization steps to detect and remove technical artifacts or other systematic biases. A Python implementation of this pipeline is available at https://github.com/csbio/BEAN-counter.

CG-TARGET is a pipeline for predicting the molecular targets of compounds from chemical-genetic interaction profiles. It leverages the phenomenon that a compound's chemical-genetic interaction profile will be similar to the genetic interaction profile of its target(s); as such, CG-TARGET uses a reference genetic interaction network to interpret the provided chemical-genetic interaction profiles. Target predictions are first made at the level of individual genes, followed by aggregation of these individual gene scores into process or pathway prediction scores in order to improve statistical confidence. An R implementation of this pipeline is available at https://github.com/csbio/CG-TARGET.

These computational toolsets have been applied to analyze more than 18,000 chemical-genetic interaction screens in *S. cerevisiae*. Validation experiments provide convincing evidence that CG-TARGET has the power to predict a compound's mechanism of action at the resolution of biological processes or pathways from a single chemical-genetic interaction profile. These pipelines have enabled the functional annotation of thousands of compounds and are readily adaptable to other compound collections and mutant libraries.

Y516 One library to make them all: streamlining the creation of yeast libraries via a SWAp-Tag strategy. *U. Weill*[1], I. Yofe[1], M. Meurer[2], S. Chuartzman[1], E. Zalckvar[1], O. Goldman[1], S. Ben-Dor[1], C. Schütze[3], N. Wiedemann[3], M. Knop[2], A. Khmelinskii[2], M. Schuldiner[1]. 1) Weizmann Institute of Science, Rehovot, IL; 2) Zentrum für Molekulare Biologie der Universität Heidelberg (ZMBH), DKFZ-ZMBH Alliance, Heidelberg, Germany; 3) Institut für Biochemie und Molekularbiologie, ZBMZ Universität, Freiburg, Germany.

The yeast Saccharomyces cerevisiae is ideal for systematic studies relying on collections of modified strains (libraries). Despite the significance of yeast libraries and the immense variety of available tags and regulatory elements, only a few such libraries exist, as their construction is extremely expensive and laborious. To overcome these limitations, we developed a SWAp-Tag (SWAT) method that enables one parental library to be modified easily and efficiently to give rise to an endless variety of libraries of choice. To showcase the versatility of the SWAT approach, we constructed and investigated a library of ~1,800 strains carrying SWAT-GFP modules at the amino termini of endomembrane proteins and then used it to create two new libraries (mCherry and seamless GFP). Our work demonstrates how the SWAT method allows fast and effortless creation of yeast libraries, opening the door to new ways of systematically studying cell biology.

Y517 NGS for "No-pain Genetic Screens": Using transposons and Next-Gen Sequencing to unveil all important yeast loci in one go. *A. Michel*, P. Kimmig, B. Kornmann. ETH Zurich, Zurich, CH.

Yeast genetic screens have been absolutely instrumental in our understanding of cell biology. Yet they remain tedious and oftentimes incomplete. Next generation sequencing on the other hand is fast and exhaustive. I have implemented a transposon-based approach combined with deep sequencing to define the complete set of genes that are essential for growth in a particular condition, in one go. The idea is to saturate the yeast genome with independent transposon insertions. Transposons cannot insert in genes that are essential in a given condition. Deep-sequencing of the transposon-genome junctions of the whole library identifies the locations that tolerate the presence of the transposon and allows to deduce those that cannot, revealing the corresponding set of essential genes. The strength of the method lies on the fact that it interrogates the entire genome at once and is readily amenable to multiple growth conditions for comparison. When used to compare different genetic backgrounds, it reveals genetics interactions. When applied to compare drug-treated to untreated cells, it reveals the set of genes conferring resistance or sensitivity to the drug. In addition to identifying essential genes, this method also generates informative alleles. For instance, transposon insertions can yield truncations of essential genes, allowing to map functional protein domains.

Our method thus allows to screen the yeast genome with an unprecedented throughput and resolution.

Y518 Exploring Functional Genetic Suppression Interactions on a Global Scale. *J. van Leeuwen*[1], C. Pons[2], J. Mellor[1], T. Yamaguchi[1], M. Costanzo[1], C. Myers[2], B. Andrews[1], F. Roth[1], C. Boone[1]. 1) University of Toronto, Toronto, ON, Canada; 2) University of Minnesota, Minneapolis, MN, USA.

Functional genetic suppression interactions occur when the phenotypic defects caused by one mutation are rescued by a mutation in a second gene. To explore the principles of genetic suppression, we collected both literature-curated and unbiased experimental data to map a large-scale suppression network among yeast genes. We found that most suppression pairs involve functionally related genes that are often co-annotated or co-expressed, or that are encoding co-localized proteins or members of the same pathway or complex. Although the suppression network includes interactions identified in other genetic networks, most suppression interactions identify novel functional relationships. For example, we exploited the suppression network to assign a possible function as a novel phospholipid scramblase for the previously uncharacterized gene *ANY1* (*YMR0101W*), a detailed mechanistic prediction that could not be made using other available genetic interaction data. Genetic suppression also involved general regulatory mechanisms associated with protein degradation, mRNA decay, and metabolic rewiring. Whole-genome sequencing of >300 yeast strains, many of which were derived from the yeast deletion mutant collection, revealed additional frequent loss-of-function mutations in a set of specific genes, including *WHI2*, *IRA1*, *IRA2*, and *RIM15,* all of which encode negative regulators of Ras signaling and its role in cell cycle progression. These mutations do not affect exponential cell growth but cause a delay in the onset of stationary phase, which appears to select for their enrichment within a propagating population. Our data allow us to formulate some fundamental mechanisms of functional suppression.

Y519 Lee Hartwell Lecture. From Yeast to Worms and Beyond: Folding Dynamic Chromatin. *Susan Gasser*. Friedrich Miescher Institute for Biomedical Research, Basel, CH.

no abstract submitted

Y520 The yeast polo kinase, Cdc5, inhibits cell growth and affects nuclear morphology during a mitotic arrest. *A. D. Walters*, O. Cohen-Fix. NIDDK/NIH, Bethesda, MD.

Normal cells of a given type possess nuclei of a particular size and shape and maintain a constant nuclear:cell volume ratio. It has been known for many years that abnormalities in nuclear size and morphology are hallmarks of cancer and aging. However, our understanding of the factors that determine nuclear size and shape remains poor. In higher eukaryotes, the nuclear envelope (NE) must expand after it is reformed at the end of mitosis to allow for chromosome decondensation. In yeast, which undergo closed mitosis, the NE must expand to allow chromosome segregation and the formation of two daughter nuclei. The mechanisms by which NE expansion is achieved and controlled are unknown.

Work in our lab has shown that when *S. cerevisiae* is delayed in mitosis the NE continues to expand despite the fact that chromosome segregation is paused, and a nuclear extension, or "flare", is formed adjacent to the site of the nucleolus. We hypothesize that flare formation allows maintenance of the nuclear:cell volume ratio in the face of continued NE expansion during an arrest of cell growth. Through a genetic screen, we have discovered that reduced activity of Cdc5, a key cell cycle regulator, causes a no-flare phenotype, where the nucleus remains round during a mitotic arrest. Our previous experiments have shown that Cdc5 is not affecting nuclear morphology through rDNA condensation or any of its other known roles in mitosis. We have also shown that the nuclei of *cdc5-nf* mutants expand isometrically during a mitotic arrest, indicating that the no-flare phenotype is not a result of reduced NE expansion. In our current work, we found that *cdc5-nf* cells grow significantly more than WT during a mitotic arrest, indicating that Cdc5 plays a role in inhibiting cell growth. We tested whether the increased cell growth in *cdc5-nf* is the cause of the no-flare phenotype, reasoning that in WT a flare forms because cell growth is inhibited while NE expansion continues, whereas in *cdc5-nf*, continued cell growth could allow isometric nuclear expansion without disturbing the nuclear:cell volume ratio. We inhibited cell growth in *cdc5-nf* using cycloheximide or mutations in the Sec pathway. However, inhibition of cell growth in *cdc5-nf* did not restore the flared nuclear phenotype. This result demonstrates that Cdc5 plays a role in the inhibition of cell growth and regulation of nuclear morphology through different pathways during a mitotic arrest, and that Cdc5 is required for specifying the site of the nucleolus for nuclear expansion during a mitotic delay.

Y521 Reconstitution of the microtubule nucleation system of *Candida albicans*. *E. Schiebel*[1], T. Lin[1], A. Neuner[1], D. Flemming[2], R. Arkowitz[3]. 1) Center for Molecular Biology, University of Heidelberg, Heidelberg, DE; 2) Biochemistry Center, University of Heidelberg, Heidelberg, DE; 3) Institute of Biology Valrose, University of Nice, Nice, FR.

Microtubules are hollow cylinders composed out of alpha/beta-tubulin with essential functions in cell architecture, cell movement and chromosome segregation in mitosis and meiosis. Microtubules are dynamic polymers that assemble from the heterodimer alpha/beta-tubulin in a process known as microtubule nucleation. gamma-tubulin, a member of the tubulin family, functions in microtubule nucleation by providing a template for the assembly of alpha/beta-tubulin into microtubules. How does gamma-tubulin provide this template function? gamma-tubulin assembles together with the proteins Spc97/Gcp2 and Spc98/Gcp3 into the small gamma-tubulin complex (gamma-TuSC). gamma-TuSC oligomerizes into a left-handed spiral (the alpha/beta-tubulin template) upon interaction with receptors (gamma-TuR) at the yeast spindle pole body (SPB), the microtubule organizing centre (MTOC). Spc110 is one such gamma-TuR on the nuclear side of the SPB while Spc72 has this function on the cytoplasmic side. Therefore, Spc110 and Spc72 are essential for the organization of nuclear end cytoplasmic microtubules, respectively. Budding yeast *Saccharomyces cerevisiae* has the simplest microtubule nucleation system of all model organisms (gamma-TuSC, Spc72 and Spc110). In *Schizosaccharomyces pombe* and higher eukaryotes, microtubule nucleation requires additional factors named GCP4, GCP5, GCP6, the "mitotic-spindle organizing protein associated with a ring of gamma-tubulin 1" (Mzt1) and Nedd1 (*Drosophila* and human cells). Interestingly, the opportunistic pathogen *Candia albicans* represents an intermediate between *S. cerevisiae* and the more complex microtubule nucleation systems of higher eukaryotes. The *C. albicans* genome encodes gamma-tubulin *CaTUB4*, *CaSPC97/GCP2*, CaSPC98/GCP3, the receptors *CaSPC72* and *CaSPC110* and *MZT1*. Here we report the reconstitution of the microtubule nucleation system of *C.*

albicans with purified components and the analysis of their function *in vivo*. This analysis provides important insights into the function of Mzt1 and how *S. cerevisiae* bypassed the requirement of the normally essential *MZT1* gene.

Y522 Capture-shrinkage of astral microtubules by budding yeast dynein in cells lacking cortical endoplasmic reticulum tethering proteins Scs2 and Scs22. *Wei-Lih Lee*, Safia Omer, John Beckford. University of Massachusetts Amherst, Amherst, MA.

Cytoplasmic dynein at the cell cortex exerts pulling forces on astral microtubules powering spindle movements during asymmetric cell divisions in a variety of organisms. In budding yeast, the only mechanism of dynein-mediated “cortical pulling" known to exist is thought to occur via side-on interactions (pulling along the lattice of microtubules), as exhibited by sliding of astral microtubules along the cortex during spindle movements across the mother-bud neck. Whether dynein mediates end-on capture-shrinkage of microtubules and how dynein is regulated between side-on and end-on interactions with microtubules are not known. Here we show by direct quantitative imaging that dynein uses end-on pulling mechanism for spindle positioning in cells lacking the cortical endoplasmic reticulum (ER) attachment molecules Scs2 and Scs22. We found that *scs2Δ scs22Δ* cells displayed a dramatic loss of cortical Num1 patches (dynein anchorage sites), exhibiting fewer than four Num1-GFP patches compared to >10 in wild-type cells. Quantitative immunoblot analysis of Num1 protein revealed that its level was unaffected by deletions of *scs2* and *scs22*, indicating that the loss of Num1-GFP patches was not due to a defect in protein stability. Interestingly, despite being at a lower density, the remaining Num1-GFP patches in *scs2Δ scs22Δ* cells, seen primarily at the bud tip and the distal end of mother cortex, quantitatively rescued the spindle misorientation and binucleate phenotypes of *num1Δ*, indicating functionality in the dynein-mediated spindle orientation pathway. We found that dynein and dynactin components co-localized with the residual Num1 patches in *scs2Δ scs22Δ* cells. Strikingly, two-color imaging of spindle movements showed that these Num1 patches mediate capture-shrinkage of astral microtubule plus ends, generating pulling forces that rescue misaligned spindles into the mother-bud neck. Disrupting Num1-dynein interaction (using *num1^{LL}* mutant allele), but not deleting Kar9 and Bud6 (the canonical capture-shrinkage pathway), abolished end-on capture-shrinkage of microtubule plus ends, demonstrating that dynein mediates spindle movements across the mother-bud neck via end-on interactions in these cells. These findings explain the long-standing enigma reported for yeast dynein from *in vitro* studies and indicate that cortical ER regulates side-on versus end-on mechanisms of dynein-mediated “cortical pulling”.

Y523 Role of the microtubule cytoskeleton in the regulation of Cdc42 dynamics. *M. Rodriguez Pino*, Illyce Nunez, Fulvia Verde. University of Miami, Miami.

Schizosaccharomyces pombe is a great model system to understand the signaling mechanisms regulating polarized cell growth. Upon the completion of mitosis, *S. pombe* cells grow in a monopolar fashion from their old tips in a process termed Old End Takes Off (OETO). Once the cell reaches a certain length, growth is activated in the second tip through a process called New End Take Off (NETO), resulting in bipolar growth.

Active Cdc42 GTPase, a key regulator of cell polarity, displays oscillatory dynamics that are anti-correlated at the two cell tips in fission yeast. This system globally controls active Cdc42 distribution, modulating cellular dimensions, and controlling the activation of growth at the secondary growing tip (Das, et al., 2012). Mathematical modeling and experimental analysis suggest Cdc42 dynamic oscillations result from the coordinated function of Cdc42 regulators, including Cdc42 GEF proteins, Gef1 and Scd1, Cdc42 GAP protein, Rga4, and Cdc42-dependent Pak1 kinase, in an interplay of positive and negative feedback mechanisms.

Here, we report that the microtubule cytoskeleton is required for the regulation of Cdc42 GTPase activation. Cells treated with the microtubule depolymerizing agent MBC show asymmetrical distribution of active Cdc42 and delay bipolar growth activation (NETO) (Das et al., 2015). Similarly, cells expressing a mutated form of the microtubule tip–associated protein Tea4, which is unable to target the phosphatase Dis1 to the growing tip, displayed asymmetrical Cdc42 activity, a phenotype that is also observed with *gef1Δ* mutants (Das et al., 2015). We find that conserved NDR kinase Orb6 negatively regulates Cdc42 GEF Gef1, an orthologue of mammalian TUBA/DNMBP. A mutated form of Cdc42 GEF Gef1 that cannot be phosphorylated by Orb6 kinase can bypass the microtubule-mediated requirement for NETO. Furthermore, the levels of Orb6-mediated phosphorylation of Gef1 are reduced upon over-expression of Tea4. Thus, the microtubule cytoskeleton opposes Orb6-mediated Gef1 phosphorylation, either by protecting Gef1 from interacting with Orb6, or through the recruitment of a phosphatase needed to dephosphorylate Gef1. These results suggest the presence of a self-organizing microtubule cytoskeleton that regulates Gef1 phosphorylation and Cdc42 activity during morphology control.

Y524 Spindle pole body assembly into the nuclear envelope in budding and fission yeast. *Sue L. Jaspersen*[1,2], Andrew J. Bestul[1], Jingjing Chen[1]. 1) Stowers Inst Med Res, Kansas City, MO; 2) University of Kansas Medical Center.

The double lipid bilayer of the nuclear membrane serves as a physical barrier to restrict access of macromolecules to genetic material inside the nucleoplasm in all eukaryotes. Compartmentalization is at the heart of transcriptional and translational control. However, the nuclear envelope (NE) represents an obstacle to cells during mitosis since the cytoplasmic cytoskeleton must interact with nuclear DNA to ensure accurate chromosome segregation. In most higher eukaryotes, the spindle forms after NE fragmentation in early mitosis, but, in fungi the NE remains intact throughout cell division and yeast microtubule organizing centers, known as spindle pole bodies (SPBs), gain access to chromosomes via insertion into the NE. Membrane insertion of SPBs is thought to be mechanistically similar to that of de novo nuclear pore complex (NPC) assembly, yet how both complexes interact with the NE to promote cell cycle specific changes in its structure is poorly understood. Central to addressing this question is the ability to 1) visualize assembly intermediates and 2) detect proteins that localize permanently or transiently to these structures. Because *Saccharomyces cerevisiae* and *Schizosaccharomyces pombe* SPBs are roughly ten times larger than the NPC, they were ideal to investigate how complexes are assembled into the NE. Using biochemical and genetic approaches

combined with super-resolution microscopy, we have identified factors that localize transiently or permanently to SPBs as they are inserted into the NE. These proteins are leading candidates to convert the planar NE into a highly curved pore membrane. Using epistasis and co-localization studies, we have put factors into an assembly pathway and have used mutant alleles to provide evidence that some lead to localized changes in NE structure. Determining how SPBs interact with the NE will provide insight into the ways that their metazoan counterparts (centrosomes) regulate their numbers and control events such as NE breakdown.

Y525 Investigating the Role of Septin Phosphorylation in Controlling of Septin Organization at Cytokinesis. *M. McQuilken*[1], A. Grassetti[1], A. Verma[2], G. Harris[2], S. Gerber[1], S. Abrahamsson[3], R. Oldenbourg[2], A. Gladfelter[1]. 1) Dartmouth College, Hanover, NH; 2) Marine Biological Laboratory, Woods Hole, MA; 3) The Rockefeller University, New York, NY.

Septins are conserved filament-forming proteins that act in cytokinesis, membrane remodeling, cell polarization, and migration. They closely associate with membranes and, in some systems, components of the cytoskeleton. Although septin function is critical for diverse cell events, it is not well understood how they assemble *in vivo* or how they are remodeled throughout the cell cycle. In budding yeast, septins assemble initially as a patch and ring that then flips into a collar at the mother-bud neck as the bud emerges. Late in the cell cycle the collar splits into two rings that generally will be disassembled prior to start of the next cell cycle. The orientation of the dipole moment of GFP has been well established, and thus, constraining GFP to an endogenous septin allows for an assessment of septin organization *in vivo* by polarization microscopy. Polarized fluorescence microscopy analysis has previously shown that septins are arranged in ordered, paired filaments and undergo a coordinated 90° reorientation during cytokinesis *in vivo*. We hypothesized that the reason for this reorganization is the presence of two unequal and differentially arranged septin populations within a septin collar at the mother-bud neck and that over the course of the cytokinesis, the dominant population is no longer enriched in the higher order structure. Data from our lab and others have confirmed a decrease in septin concentration in the collar at mother-bud neck during cytokinesis and we see the kinetics of the decrease depend on known septin regulators including the kinase Gin4. Our goal is to understand the mechanisms regulating changes in septin abundance at septin ring splitting. We have used polarization microscopy to screen mutant yeast strains with abnormally organized septins and have identified septin interactors important for distinct aspects of the assembly, stability, and reorganization of septins. We predicted that these identified regulators control post-translational modifications to trigger reorganization of a subset of septins during cytokinesis. We therefore performed mass spectroscopy on septins synchronized at different stages of the cell cycle and found that there is a difference in the phosphorylation of the N- and C-terminal septin-interacting interfaces depending on whether septins are in collars or split rings. These data suggest that selective phosphorylation of septins can control their polymerization and localization in a cell cycle dependent manner at cytokinesis.

Y526 The respiration/fermentation switch in yeast requires protein aggregation. *Kobi Simpson-Lavy*[1], Mark Johnston[2], Martin Kupiec[1]. 1) Tel Aviv University, Tel Aviv, IL; 2) University of Colorado-Denver, Aurora, CO, USA.

Amyloidogenic proteins (such as Huntingtin) and prions are sequestered under stress conditions or their overexpression into special particles/compartments called IPOD and JUNQ. This process involves the chaperones Hsp104, Btn2 and Cur1. Utilization of non-fermentable carbon sources requires the activity of the Snf1 protein kinase. Snf1 is active in the absence of glucose and regulates the expression and activity of proteins involved in respiration. We have identified two new regulators of Snf1 activity in *S. cerevisiae.* These new regulators (Vhs1 and Sip5) control the aggregation of the Snf1 activator Std1 in response to glucose via the asparagine-rich region of Std1. Interestingly, aggregated Std1 localizes to the IPOD under ambient conditions and this utilizes the same chaperones used by amyloidogenic proteins and prions under pathological or stressful conditions. Thus, amyloidogenic aggregation is a normal, non-pathological physiological state that can be used to regulate central metabolic processes. These results shed light on the evolutionary role of protein aggregation in eukaryotes and have implications for our understanding of cancer and neurodegenerative diseases.

Y527 SNX-BAR proteins contribute to autophagy via trafficking of lipids required for autophagosome-vacuole fusion. *R. J. Chi*[1], M. Ma[2], S. Kumar[2], J. Wang[2], M. Babst[3], C. Burd[2]. 1) University of North Carolina at Charlotte, Charlotte, North Carolina; 2) Yale School of Medicine New Haven, Connecticut; 3) University of Utah, Salt Lake City, Utah.

The yeast *SNX4* family of sorting nexins containing a BAR domain (SNX-BARs), Snx4/Atg24, Snx41, and Snx42/Atg20, are components of endocytic recycling and autophagy trafficking pathways. We show that these proteins possess membrane remodeling activity in vitro and coat endosome-derived transport carriers in vivo. Endosomes decorated by Snx4 proteins are also decorated with retromer SNX-BARs, but each SNX-BAR coats a distinct carrier that buds from the endosome, indicating that, in contrast to current models, the *SNX4* and retromer pathways originate from a common endosome. Cells lacking Snx4 family proteins display a modest deficiency in autophagy that is severely exacerbated when mitochondrial phosphatidylethanolamine synthesis is ablated. Under these conditions, the lipid content of endosome-related organelles is perturbed and autophagosomes accumulate within the cytoplasm as a result of deficient fusion with the lysosome-like vacuole. SNARE-mediated autophagosome-vacuole fusion is restored by increasing phosphatidylethanolamine biosynthesis via alternative pathways, revealing a role for sorting nexins in controlling local pools of glycerophospholipids.

Y528 Rewiring of lipid metabolism in a yeast mutant devoid of the major membrane lipid phosphatidylcholine. *A. de Kroon*[1], X. Bao[1], F. Holstege[2], M. Mari[3], C. Klose[4]. 1) Utrecht University, NL; 2) UMCU, Utrecht, NL; 3) UMCG, Groningen, NL; 4) Lipotype GmbH, Dresden, FRG.

The composition of the membrane lipid matrix determines the physical properties of a biological membrane including membrane surface charge, membrane fluidity and membrane intrinsic curvature. For proper membrane function it is essential that these parameters are maintained in the appropriate range. Yeast is the eukaryote of choice for investigating the regulatory mechanisms governing membrane lipid

composition because the organism is extremely tolerant to manipulation of membrane lipid biosynthesis. Phosphatidylcholine (PC) is a highly abundant membrane lipid in most eukaryotes, and is generally considered essential. With the goal of elucidating the function(s) of PC we have been studying the yeast mutant *cho2opi3* that lacks the methyltransferases for converting phosphatidylethanolamine (PE) into PC and relies on supplementation with choline for PC synthesis by the CDP-choline route. Recently, we isolated *cho2opi3* suppressor (*cho2opi3*S) clones that lost the auxotrophy for choline. These clones exhibit decent growth on fermentable carbon source in the complete absence of choline or choline substitutes. Lipidome analysis demonstrated the absence of PC and revealed that the suppressors exhibit strongly increased synthesis of fatty acids and triglycerides. This is accompanied by a shortening of the average acyl chain length and increased acyl chain desaturation. The changes in fatty acid profile are consistent with the maintenance of membrane physical properties since they reduce the non-bilayer propensity of PE, which has replaced PC as most abundant membrane lipid. At the ultrastructural level, EM revealed massive lipid droplet accumulation and aberrant mitochondrial and vacuolar structure in *cho2opi3*S cells. After return to choline-supplemented medium the suppression of choline auxotrophy is gradually lost, indicating that it is not caused by a mutation. Whole genome sequencing confirmed the lack of common SNPs between suppressors, but instead revealed that the suppressors acquired aneuploidy. Genome-wide transcript profiling is underway to obtain additional clues as to the molecular mechanism of the adaptation that renders PC biosynthesis redundant. Based on the results obtained so far, the hypothesis is put forward that the aneuploidy confers increased synthesis of fatty acids, which is required to shorten the average acyl chain length and thus sustain yeast growth in the absence of PC.

Y529 The lysine acetyltransferase complex NuA4 regulates cellular phosphatidylinositol-4-phospahate and phospholipid metabolism. *L. Dacquay*, M. Kennedy, A. Flint, J. Butcher, A. Stinzi, K. Baetz. Ottawa Institute of Systems Biology, Department of Biochemistry, Microbiology, and Immunology, University of Ottawa, Ottawa, Canada.

Understanding the regulation of phosphatidylinositol-4-phospahate (PI-4-P) homeostasis is important due to its critical roles in trafficking and proliferation. In Saccharomyces cerevisiae, the conserved lipid-binding proteins Sec14 and Osh4 regulate Golgi-localized PI-4-P homeostasis by either increasing or decreasing its levels respectively. It remains poorly understood how cells compensate in response to changes in the steady-state levels of PI-4-P. Our recent findings suggest that lysine acetyltransferase (KAT) regulation of transcription are contributing to the cellular response to PI-4-P deficiencies. Through a systematic analysis of all KAT deletion mutants, we found that mutants of the NuA4 KAT complex, including *eaf1*, are hypersensitive to *SEC14* inactivation and *OSH4* overexpression, two conditions where Golgi PI-4-P levels are depleted. Through transcriptome profiling, we determined that in PI-4-P deficient conditions, NuA4 regulates the transcription of the essential genes *CDS1*, which catalyzes CDP-DAG biosynthesis, and *BCP1*, which regulates the localization of the PI-4,5-P_2 kinase Mss4. Genetic analysis and microscopy analysis confirms that NuA4-dependent regulation of *CDS1* and *BCP1* is essential to compensate for defects in Sec14 and decreases in PI-4-P. Altogether, we have discovered a new role for the lysine acetyltransferase NuA4 as a regulator of PI-4-P and phospholipid metabolism.

Y530 An unexpected role for casein kinases in glucose sensing and signaling. *C. Snowdon*, M. Johnston. University of Colorado, Aurora, CO.

Saccharomyces cerevisiae prefers glucose as its carbon source, and intercellular glucose acts as an important signaling molecule to regulate many physiological processes, so yeasts have evolved sophisticated signaling pathways to regulate the uptake and metabolism of glucose. The Snf3/Rgt2-Rgt1 (SRR) glucose-sensing pathway enables yeast cells to detect extracellular glucose and transmit an intercellular signal that induces expression of hexose transporter (hxt) genes. The yeast casein kinases (YCKs) are key players in this signaling pathway, and are thought to be responsible for transmission of the glucose signal. The current model of the SRR signaling pathway suggests that binding of glucose to the glucose sensors activates YCKs to phosphorylate the transcriptional co-repressors Mth1 and Std1, targeting them for degradation and thereby relieving repression of *Hxt* genes. However, we have evidence for an upstream role for YCKs in the SRR signaling pathway: (i) overexpression of Rgt2 rescues glucose signaling in a strain lacking YCK; (ii) the C-terminal tail of Rgt2 is phosphorylated by YCK, and (iii) Rgt2 phosphorylation is necessary for signaling; (iv) Rgt2 phosphorylation promotes interaction of the Mth1 and Std1 co-repressors with the Rgt2 glucose sensor. These results lead us to a model in which the YCKs act upstream of the glucose sensors to phosphorylate the C-terminal tail of the glucose sensors to establish a functional interaction site for the co-repressors, bringing them to the glucose sensor to receive and transmit the glucose signal.

12TH INTERNATIONAL CONFERENCE ON ZEBRAFISH DEVELOPMENT AND GENETICS

Plenary and Platform Session Abstracts

12Th International Conference On Zebrafish Development And Genetics

SCHEDULE AT-A-GLANCE

Wednesday, July 13		
2:00pm-9:30pm	Speaker Ready Room Open	Hall of Cities - Anaheim
7:00pm-9:00pm	Scientific Session: Regeneration and Stem Cells	Grand Ballroom 7A
9:00pm-11:00pm	Opening Mixer with Exhibits	Cypress Ballroom
Thursday, July 14		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities -Anaheim
7:45am-10:00am	Genetics and Determinants of Health Joint Plenary Session	Palms Ballroom
8:00am-4:00pm	Exhibits Open	Cypress Ballroom
9:00am-8:00pm	Demo Room: MOD (FlyBase, MGI, SGD, WormBase, Zfin) Demo Room Open	Palms Ballroom Canary 3-4
10:30am-12:30pm	Scientific Session: Early Development and Morphogenesis Neural Circuits, Neurophysiology and Behavior	Grand Ballroom 7A Grand Ballroom 7B
12:30pm-1:30pm	Mentoring Roundtables #1	North Tower - Harbor Beach
12:30pm-1:30pm	Speaking Up for Genetics and Model Organism Research	Crystal Ballroom H
1:30pm-3:30pm	Poster Presentations 1:30pm-2:30pm: Even-numbered posters 2:30pm-3:30pm: Odd-numbered posters	Cypress Ballroom
1:30pm-3:30pm	GeneticsCareers Center and Job Fair	Cypress Ballroom 1C
4:00pm-6:00pm	Concurrent Scientific Sessions: Cardiac Development Gene Regulation and RNA Biology	 Grand Ballroom 7A Grand Ballroom 7B
4:00pm-6:00pm	Plenary Session and Workshop for Undergraduate Researchers	North Tower - Sawgrass
7:45pm-9:45pm	Scientific Session: Neurobiology	Grand Ballroom 7A
10:00pm-11:30pm	*Science Cafe Event	Palms Ballroom Sabal
Friday, July 15		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities - Anaheim
8:00am-9:30am	Concurrent Scientific Sessions: t Models of Human Disease Evolution	 Grand Ballroom 7A Grand Ballroom 7B
8:00am-4:30pm	Exhibits Open	Cypress Ballroom
9:00am-8:00pm	Demo Room: MOD (FlyBase, MGI, SGD, WormBase, Zfin) Demo Room Open	Palms Ballroom Canary 3-4
10:00am-12:00pm	Concurrent Scientific Session: Emerging Technologies Imaging Signaling Organogenesis (Mesoderm, Endoderm, Ectoderm)	 Grand Ballroom 1-2 Grand Ballroom 7B Grand Ballroom 7A
12:00pm-1:30pm	*Editor's Panel Discussion and Roundtable	North Tower - Harbor Beach

** Ticketed Event*

#TAGC16

Friday, July 15 (continued)		
1:30pm-3:30pm	Poster Presentations 1:30pm-2:10pm: "A" poster authors present 2:10pm-2:50pm: "B" poster authors present 2:50pm-3:30pm: "C" poster authors present	Cypress Ballroom
1:30pm-3:30pm	GeneticsCareers Center	Cypress Ballroom 1C
2:00pm-2:45pm	GeneticsCareers Workshop - Nailing the Job Talk	Cypress Ballroom 1B
4:00pm-6:00pm	Scientific Session: Highlighted Talks, Awards Ceremony and Community Meeting	Grand Ballroom 7A
6:00pm-7:30pm	*Women in Genetics Panel and Networking	North Tower - Harbor Beach
7:30pm-9:30pm	Development and Evolution Joint Plenary Session	Palms Ballroom
Saturday, July 16		
7:00am-5:00pm	Speaker Ready Room Open	Hall of Cities - Anaheim
8:00am-10:00am	Workshops: See topics and descriptions under the Workshop Section	Multiple locations
8:00am-12:00pm	Exhibits Open	Cypress Ballroom
8:00am-9:00am	Trainee Bootcamp Workshops: Session 1	North Tower
9:00am-10:00am	Trainee Bootcamp Workshops: Session 2	North Tower
10:00am-12:00pm	Poster Presentations 10:00am-11:00am Odd-numbered posters 11:00am-12:00pm Even-numbered posters	Cypress Ballroom *(Posters must be removed by 1pm)*
10:00am-12:00pm	GeneticsCareers Center	Cypress Ballroom 1C
10:30am-11:15am	GeneticsCareers Workshop	Cypress Ballroom 1B
12:15pm-1:45pm	*Mentoring Roundtables #2	North Tower - Harbor Beach
1:45pm-3:45pm	Concurrent Scientific Sessions: Neural Development and Regeneration Cancer	 Grand Ballroom 7A Grand Ballroom 7B
4:00pm-6:00pm	Scientific Session: Models of Human Disease	Grand Ballroom 7A
7:30pm-9:30pm	Concurrent Scientific Session: Haematopoiesis and Vascular Biology Cell Biology and Polarity	 Grand Ballroom 7A Grand Ballroom 7B
Sunday, July 17		
8:00am-10:00am	Scientific Sessions: Genome Editing	Grand Ballroom 7A
10:30am-12:30pm	Technology and its Application Joint Plenary Session	Palms Ballroom

** Ticketed Event*

Z531 Modulation of tissue repair by regeneration enhancer elements. *Junsu Kang*[1], Jianxin Hu[2], Ravi Karra[1], Amy L. Dickson[1], Valerie A. Tornini[1], Gregory Nachtrab[1], Matthew Gemberling[1], Joseph A. Goldman[1], Brian L. Black[2], Kenneth D. Poss[1]. 1) Duke University, Durham, NC; 2) UCSF, San Francisco, CA.

How tissue regeneration programs are triggered by injury has received limited research attention. Here we investigate the existence of enhancer regulatory elements that are activated in regenerating tissue. Transcriptomic analyses reveal that leptin b (lepb) is highly induced in regenerating hearts and fins of zebrafish. Epigenetic profiling identified a short DNA sequence element upstream and distal to lepb that acquires open chromatin marks during regeneration and enables injury-dependent expression from minimal promoters. This element could activate expression in injured neonatal mouse tissues and was divisible into tissue-specific modules sufficient for expression in regenerating zebrafish fins or hearts. Simple enhancer-effector transgenes employing lepb-linked sequences upstream of pro- or anti-regenerative factors controlled the efficacy of regeneration in zebrafish. Our findings provide evidence for 'tissue regeneration enhancer elements' (TREEs) that trigger gene expression in injury sites and can be engineered to modulate the regenerative potential of vertebrate organs.

Z532 A screen for epigenetic regulators reveals a requirement for Ing4 in HSC specification and function. *K. L. Kathrein*[1], V. Binder[2], M. Ammerman[1], S. Yang[1], E. M. Durand[1], L. I. Zon[1,3]. 1) Stem Cell Program and Division of Hematology/Oncology, Children's Hospital Boston, Boston, MA; 2) Department of Hematology and Oncology, Dr. von Hauner Children's Hospital, Ludwig-Maximilians University, Munich, Germany; 3) Howard Hughes Medical Institute, Boston Children's Hospital/Harvard Medical School, Boston, MA.

Hematopoietic stem cells (HSCs) are capable of self-renewal and differentiation into all mature hematopoietic lineages. This is regulated by transcription factors and chromatin factors to orchestrate chromatin structure and establish an epigenetic code that facilitates gene expression. To uncover chromatin factors that are necessary for the establishment of HSCs, we conducted a reverse genetic screen in the zebrafish using morpholinos to target 488 chromatin remodeling factors. We identified 29 genes that alter HSC marker expression, *c-myb* and *runx1*, upon knockdown. Several components of chromatin remodeling complexes already known to regulate hematopoiesis were required for HSC development in our screen. We also found components from complexes that have no known role in HSCs, including the iSwi and Hbo1 complexes. Four members of the Hbo1 complex, Ing4, Phf16, Hbo1, and Brd1, show loss of HSC marker expression upon knockdown. This complex regulates gene expression through the binding of H3K4me3 by Ing4, which results in localized histone acetylation by Hbo1. Ing4 has also been shown to negatively regulate the transcription factor NF-kB through sequestration of the RelA component of NF-kB. To test the function of the complex in HSCs, we used low doses of morpholinos to partially inhibit expression of each complex member. With modestly reduced levels of *ing4*, *brd1*, and *jade3* individually, we see no effect on HSC specification. However, when combined we see a loss of marker expression, suggesting they genetically interact to regulate HSC specification. Using ChIP-seq for ING4 in human CD34+ cells, we show that ING4 is bound to many regulators of blood development including *c-myb*, *lmo2*, *runx1* and *ikaros*. Ing4 is also bound to several NF-kB target genes including *il-1b, il-6, il-8, and il-20*, as well as a subset of *ifna* associated genes. Zebrafish lacking *ing4* expression show an increase in NF-kB target gene expression, suggesting that loss of Ing4 results in an overabundance of NF-kB target gene signaling. Mice lacking Ing4 also have altered hematopoiesis. These mice exhibit a differentiation block in short-term HSCs (ST-HSCs) and increased NF-kB target gene expression in HSCs and progenitor cells. Loss of Ing4 has a cell autonomous effect on HSCs where long-term HSCs are unable to repopulate recipient animals in competitive transplantation assays. Surprisingly, Ing4 null multipotent progenitors (MPPs) cells outperform their wildtype counterparts in competitive transplantation, suggesting that MPPs that overcome the block at the ST-HSC stage are superior in repopulation of the niche. Concomitant loss of Ing4 and NF-kB target genes by morpholino can rescue HSC specification in zebrafish. These results suggest a novel mechanism for HSC regulation by Ing4 and the Hbo1 complex through regulation of inflammatory signaling.

Z533 Zebrafish T cells mediate organ-specific regenerative programs . *K. Kikuchi*, S. Hui, D. Sheng, K. Sugimoto, A. Rajal. Victor Chang CRI, Darlinghurst, NSW, AU.

In mammals, T cells play major roles in response to tissue injury and subsequent repair through diverse functions, including the promotion of tissue growth and scarring. Although the adaptive immune system is highly developed in regenerative vertebrates such as salamanders and fish, little is known about the contributions of T cells to scarless regeneration in these animals. Here, we demonstrate that successful tissue regeneration in the zebrafish requires a T-cell subset that has the capacity to produce tissue-specific growth factors. Using a transgenic reporter strain, we found that T cells infiltrated damaged tissues and closely associated with regenerating parenchymal cells (e.g. new neurons, proliferating cardiomyocytes). Inducible genetic ablation of T cells was associated with elevated inflammation and severely impaired spinal cord and heart regeneration as well as significantly reduced neurogenesis and cardiomyocyte proliferation. We found that spinal cord-infiltrating T cells specifically synthesised neurogenic factors, whereas heart-infiltrating T cells synthesised cardiomyocyte mitogens. Furthermore, neurogenic and cardiogenic factor administrations restored the neurogenesis and cardiomyocyte proliferation defects associated with T cell depletion. Thus, zebrafish T cells elaborate an organ-specific secretory phenotype and directly enhance spinal cord and cardiac regeneration by promoting neurogenesis and cardiomyocyte proliferation, respectively. These findings extend our understanding of the immunological regulation of organ regeneration and suggest T cell-mediated regenerative therapies for the treatment of spinal cord and cardiac damage in humans.

Z534 Production of medaka individuals derived from cryopreserved spermatogonia by allogenic transplantation. *S. Seki*[1,2], K. Kusano[1], S. Lee[1], Y. Iwasaki[1], T. Hiratsuka[1], M. Ishida[1], T. Sasado[3], K. Naruse[3], G. Yoshizaki[1]. 1) Tokyo University of Marine Science and Technology, Tokyo, JP; 2) Akita University, Akita, JP; 3) National Institute for Basic Biology, Okazaki, JP.

Although numerous inbred lines and endangered wild populations of medaka exist, the only method currently available for preserving these resources is to rear live individuals, as protocols for cryopreservation of fish eggs or embryos have not yet been successfully established due to their large size. Our group developed a novel method termed surrogate broodstock technology. By transplanting donor germ cells into recipient fish of another species, the donor germ cells mature into sperm or oocytes in recipient gonads. Importantly, the cryopreserved germ cells can be differentiated into functional oocytes. After examining cryobiological properties of medaka spermatogonia, we established a vitrification method for medaka whole testis including spermatogonia, and further established that this method can be applied for cryopreservation of zebrafish whole testis.

When vitrified spermatogonia from the *olvas-GFP* transgenic strain (body color: orange) were transplanted into larvae of a non-transgenic strain (body color: black), female recipients produced oocytes showing green fluorescence. In their gonads, there were recipient-derived oocytes together with donor-derived green fluorescent oocytes. Then, infertile triploids were used as the recipients in the next experiment. When cryopreserved spermatogonia were transplanted into triploid larvae, the mature recipients produced only sperm and eggs showing green fluorescence, which is the donor-derived characteristic. Moreover, the body colors of the offspring obtained by mating the recipient males and females were orange (100%, 1169/1169), suggesting that all of them were derived from cryopreserved spermatogonia. Thus, we succeeded in producing the donor-derived offspring by allogenic transplantation of cryopreserved spermatogonia in medaka. Finally, we confirmed that this system can be applied on vitrified testes for the production of an inbred line, or endangered wild populations (Tokyo-medaka). These techniques will facilitate the establishment of a stable and reliable system for preserving valuable medaka strains semi-permanently.

Z535 Zebrafish heart regeneration requires alleviation of cardiomyocyte genomic stress by BMP signaling. *Gilbert Weidinger*, Mohan Dalvoy, Chi-Chung Wu. Ulm University, Ulm, Germany.

In contrast to adult mammals, zebrafish can regenerate heart injuries via dedifferentiation and proliferation of differentiated cardiomyocytes in the wound border zone. Cell cycle re-entry of non-cycling cells can result in replication stress and thus DNA damage, a phenomenon that has been linked to failed homeostasis and regeneration of organ systems in aged mammals. Surprisingly, we found that a large fraction of cardiomyocytes in the regenerating heart of young zebrafish experience DNA damage, as indicated by accumulation of the phosphorylated histone variant H2a.x (gammaH2a.x). DNA damage is likely the result of replication stress caused by injury-induced cardiomyocyte cell cycle re-entry since no gammaH2a.x is detected in proliferating cardiomyocytes during physiological heart growth but occurs in the same temporal and spatial profile as cardiomyocyte cell cycle re-entry during heart regeneration. Importantly, inhibition of DNA damage response pathways results in blockage of regenerative cardiomyocyte proliferation, indicating that replication stress needs to be resolved for heart regeneration to occur.

We have recently shown that BMP signaling is activated in cardiomyocytes at the wound border and that BMP signaling is required for heart regeneration by promoting cardiomyocyte proliferation (Wu et al, *Dev. Cell* 2016). Since BMP signaling is not required for cardiomyocyte proliferation during physiological heart growth, it might regulate regeneration-specific cellular processes in cardiomyocytes, which are prerequisites for proliferation. Intriguingly, we found that inhibition of BMP signaling increases the number of gammaH2a.x positive cardiomyocytes, while pathway overactivation alleviates DNA damage, suggesting that BMP signaling is required for protection from replication stress or repair of DNA damage.

Our results surprisingly indicate that the elevated heart regenerative capacity of zebrafish might depend on efficient means to deal with replication stress and DNA damage, which are thought to impair organ regeneration in aged mammals. We propose that BMP signaling promotes heart regeneration by protecting cells from genomic stress or by augmenting DNA damage repair, a novel function of the pathway that could be conserved in other systems.

Z536 Autophagy Activation via FGF Signaling Regulates Cytoplasmic Remodeling of Regenerating Adult Zebrafish Myocytes. *Alon Kahana*, Alfonso Saera-Vila, Phillip Kish, Ke'ale Louie, Daniel Klionsky. University of Michigan, Ann Arbor, MI.

Cell identity involves both selective gene activity and specialization of cytoplasmic architecture and protein machinery. Similarly, reprogramming differentiated cells requires both genetic program alterations and remodeling of the cellular architecture. While changes in genetic and epigenetic programs have been well documented in dedifferentiating cells, the pathways responsible for remodeling the cellular architecture and eliminating specialized protein complexes are not as well understood. Here, we utilize a zebrafish model of adult muscle regeneration to study cytoplasmic remodeling during cell dedifferentiation. We describe activation of autophagy early in the regenerative response to muscle injury, while blocking autophagy using chloroquine, atg5 or beclin knockdown reduced the rate of regeneration with accumulation of sarcomeric debris. We further identify Fgf signaling through Erk2 as an important activator of autophagy in dedifferentiating myocytes. We conclude that autophagy plays a critical role in cell reprogramming by regulating cytoplasmic remodeling, facilitating the transition to a less differentiated cell identity.

Z537 Macrophages mediate the repair of brain vascular rupture through direct physical adhesion and mechanical traction. *Lingfei Luo*[1], Chi Liu[1], Chuan Wu[1], Qifen Yang[1], Jing Gao[2], Li Li[1], Deqin Yang[2]. 1) School of Life Sciences, Southwest University, Chongqing, China; 2) The Affiliated Hospital of Stomatology, Chongqing Medical University, Chongqing, China.

Hemorrhagic stroke and brain microbleeds are caused by cerebrovascular ruptures. Fast repair of such ruptures is the most promising therapeutic approach. Due to a lack of high resolution ***in vivo*** real-time studies, the dynamic cellular events involved in cerebrovascular repair remain unknown. Here, we have developed a cerebrovascular rupture system in zebrafish using multi-photon laser, which generates a lesion with two endothelial ends. ***In vivo*** time-lapse imaging showed that a macrophage arrives at the lesion and extended filopodia or lamellipodia to physically adhere to both endothelial ends. This macrophage generated mechanical traction forces to pull the endothelial ends and facilitate their ligation, thus mediating the repair of the rupture. Both depolymerization of microfilaments and inhibition of phosphatidylinositide 3-kinase or Rac1 activity disrupted macrophage-endothelial adhesion and impaired cerebrovascular repair. Our study reveals a hitherto unexpected role for macrophage in mediating repair of cerebrovascular ruptures through direct physical adhesion and mechanical traction.

Z538 Four and a Half LIM Domains 1b (Fhl1b) Is Essential for Regulating the Liver versus Pancreas Fate Decision and for beta-Cell Regeneration. *C. Shin*[1], J. Xu[1], J. Cui[2], A. Del Campo[2]. 1) School of Biology and the Parker H. Petit Institute for Bioengineering and Bioscience, Georgia Institute of Technology, Atlanta, Georgia, United States of America; 2) Max Planck Institute for Polymer Research, Mainz, Germany.

The liver and pancreas originate from overlapping embryonic regions, and single-cell lineage tracing in zebrafish has shown that Bone morphogenetic protein 2b (Bmp2b) signaling is essential for determining the fate of bipotential hepatopancreatic progenitors towards the liver or pancreas. Despite its pivotal role, the gene regulatory networks functioning downstream of Bmp2b signaling in this process are poorly understood. Through transcriptome profiling of endodermal tissues exposed to increased or decreased Bmp2b signaling, we have discovered the zebrafish gene *four and a half LIM domains 1b* (*fhl1b*) as a novel target of Bmp2b signaling. *fhl1b* is primarily expressed in the prospective liver anlage. Loss- and gain-of-function analyses indicate that Fhl1b suppresses specification of the pancreas and induces the liver. By single-cell lineage tracing, we showed that depletion of *fhl1b* caused a liver-to-pancreas fate switch, while *fhl1b* overexpression redirected pancreatic progenitors to become liver cells. At later stages, Fhl1b regulates regeneration of insulin-secreting beta-cells by directly or indirectly modulating *pdx1* and *neurod* expression in the hepatopancreatic ductal system. Therefore, our work provides a novel paradigm of how Bmp signaling regulates the hepatic versus pancreatic fate decision and beta-cell regeneration through its novel target Fhl1b.

Z539 A Meiotic-Vegetal Center Couples Oocyte Polarization with Meiosis. *Y. M. Elkouby*, A. Jemieson-Lucy, M. C. Mullins. UPenn Perelman School of Medicine, Philadelphia, PA.

Vertebrate oocyte polarity along the animal-vegetal (AV) axis has been observed for two centuries, but how it is generated was unknown. AV oocyte polarity is established by the Balbiani body (Bb), a structure conserved from insects to humans, that contains an aggregate of specific mRNAs, proteins, and organelles. The Bb specifies the oocyte vegetal pole, which is key to forming the embryonic body axes as well as the germ line in most vertebrates. How Bb formation is regulated and how its asymmetric position is established were unknown. Using quantitative image analysis, we traced oocyte symmetry breaking in zebrafish to a nuclear asymmetry at the onset of meiosis called the chromosomal bouquet. The bouquet is a universal feature of meiosis where all telomeres cluster to one pole on the nuclear envelope, facilitating chromosomal pairing and meiotic recombination. We show that Bb precursor components first localize with the centrosome to the cytoplasm adjacent to the telomere cluster of the bouquet. They then aggregate around the centrosome in a specialized nuclear cleft that we identified, assembling the early Bb. We found that the bouquet nuclear events and the cytoplasmic Bb precursor localization are mechanistically coordinated by microtubules. Thus the AV axis of the oocyte is aligned to the nuclear axis of the bouquet. We show that the symmetry breaking events lay upstream to the only known regulator of Bb formation, the Bucky ball protein. Our findings link two universal features of oogenesis, the Bb and the chromosomal bouquet, to oocyte polarization. We propose that a cellular organizer that we term the meiotic–vegetal center, couples meiosis and oocyte patterning. Our findings reveal a novel mode of cellular polarization in meiotic cells whereby cellular and nuclear polarity are aligned. We further revealed that oocytes are organized in cysts where meiotic–vegetal center formation and polarization is synchronized as shown by both live time-lapse and fixed sample data. Moreover, intercellular cytoplasmic bridges remain between oocytes in the cyst and coincide with the location of the centrosome meiotic–vegetal center, suggesting that the last mitotic oogonial division plane positions the centrosome and the meiotic–vegetal center. These results provide the first evidence for a link between polarity and cyst organization. As we show here, the zebrafish ovary provides an excellent genetic model for vertebrate germ cell differentiation, ovarian development and female reproduction.

Z540 Investigating the function of the yolk cell microtubules during zebrafish epiboly. *A. Bruce*, Z. Fei, K. Bae. University of Toronto, Toronto, Ontario, Canada.

Zebrafish epiboly involves the vegetal movement of the blastoderm and the yolk syncytial layer to enclose the yolk cell. An elaborate longitudinal microtubule array extends from the yolk syncytial layer towards the vegetal pole of the yolk cytoplasmic layer and shortening of this array is proposed to provide a vegetally directed pulling force during epiboly. Despite experimental evidence implicating yolk microtubules in normal epiboly movements, their exact function remains unclear. Furthermore, most studies have examined yolk microtubules in fixed specimens, thus little is known about their dynamics. To investigate yolk cell microtubule function, we examined the movements of the microtubule plus end associated protein EB3 fused to GFP (EB3-GFP), which binds to actively polymerizing microtubules. The current model is that the microtubule array is established before epiboly and shortens during epiboly and thus predicts very little polymerization during early epiboly stages. In contrast to this model, EB3-GFP tracking revealed widespread microtubule polymerization in the yolk syncytial layer and extensive vegetally directed microtubule growth in the yolk cytoplasmic layer from high stage to 60% epiboly. Strikingly, after 60% epiboly, EB3-GFP was not detected in the yolk cytoplasmic layer, suggesting that the yolk microtubules might be stabilized at 60% epiboly. To investigate this

further, we performed antibody staining for tyrosinated and de-tyrosinated tubulin, which are markers of dynamic and stabilized microtubules, respectively. The marker for dynamic microtubules was present at early but not late epiboly stages, while the marker for stabilized microtubules was detected at late but not early epiboly stages. We also performed FRAP experiments on embryos with fluorescently labeled microtubules and found that the recovery times were faster at early epiboly stages than at late epiboly stages. Our data are consistent with the hypothesis that yolk cell microtubules are more dynamic at early epiboly stages than at late epiboly stages, suggesting that they may perform distinct functions at these stages. Previous work suggested that the yolk cell microtubules might pull the yolk syncytial layer nuclei towards the vegetal pole starting at 60% epiboly. Thus, the yolk cell microtubules might need to be stabilized before they can function in yolk syncytial layer nuclear migration, a possibility that we are currently investigating. Overall, we found that the yolk microtubules appear to undergo a rapid growth phase during early epiboly followed by a more stabilized phase that correlates with downward movement of the yolk syncytial layer nuclei. Intriguingly, the two phases of microtubule dynamics are consistent with the timing of the initiation and progression phases of epiboly.

Z541 *Myo1D*, an unconventional myosin regulates kupffer's vesicle lumenogenesis in zebrafish. *M. Saydmohammed*, H. Yagi, T. Feinstein, D. Kostka, CW Lo, M. Tsang. University of Pittsburgh, Pittsburgh, PA.

During zebrafish development, a transient ciliated organ known as the kupffer vesicle (KV) forms and contributes to establishing laterality in the embryo. The activity of motile cilia in the KV results in asymmetric flow of extra embryonic fluid and contributes to the left-right arrangement of visceral organs. The molecular mechanisms that contribute to the formation of KV lumen still remain elusive. Recent work in *Drosophila* has identified a novel *situs inversus* gene encoding unconventional type 1D Myosin (*myo1D*). Here, we show that zebrafish *myo1D* is essential for KV lumenogenesis. Targeted mutation in the *myo1D* gene by TALENs affected the formation of KV lumen and randomized heart and gut looping. Confocal imaging of the KV formation revealed failure of the KV lumen to expand. Disrupted KV lumenogenesis in *myo1D* mutants was due to mislocalization of E cadherin and β-catenin that resulted in loss of apical basal polarity in cells that form the KV. *myo1D* is expressed maternally and only the maternal-zygotic (MZ) mutant showed defective KV formation. Defective KV lumenogenesis phenotype was recapitulated by injecting with antisense morpholino (MO) targeting the *myo1D* gene. In summary, *myo1D* is one of the earliest unconventional myosin motors expressed in zebrafish that regulate KV lumenogenesis and critical for proper left right patterning in a vertebrate.

Z542 Combinatorial signaling interactions pattern the dorsal-ventral mesodermal axis by controlling bHLH transcription factor activity. *B. L. Martin*[1], R. Row[1], G. H. Farr III[2], L. Maves[2]. 1) Stony Brook University, Stony Brook, NY; 2) Seattle Children's Research Institute, Seattle, WA.

Newly formed mesoderm is patterned into dorsal-ventral subtypes through combinatorial interactions of paracrine signaling pathways. How these signals are integrated to induce specific dorsal-ventral cell fates is not well understood. The vertebrate tailbud provides a simplified model to understand in vivo mesodermal patterning. Newly formed mesoderm in the zebrafish tailbud undergoes a binary decision to become either dorsal paraxial mesoderm, or ventral endothelial tissue. We show that tailbud mesoderm is patterned by interactions between canonical Wnt, FGF, and BMP signaling, where Wnt and FGF induce paraxial fate, and BMP promotes endothelial fate. The mechanism of signal integration of these three independent pathways is at the level of basic helix loop helix (bHLH) transcription factor activity, which produces a binary cell fate output. High bHLH activity induces paraxial fate, while low bHLH activity results in endothelial induction. Consistent with predictions from this model, we show that endothelium is the default fate of newly generated tailbud mesoderm. We extend our analysis to show that the same mechanism is responsible for the dorsal-ventral patterning of the entire mesodermal germ layer during gastrulation. Unexpectedly, this mechanism only affects dorsal-ventral mesodermal patterning and has no effect on anterior-posterior pattern, providing evidence for the molecular uncoupling of dorsal-ventral and anterior-posterior patterning downstream of Wnt, FGF, and BMP signaling.

Z543 Functional conservation of the zebrafish germ plasm organizer Bucky ball and *Drosophila* Oskar. *P. Krishnakumar*[1], S. Riemer[1], T. Lingner[1], F. Bontems[2], R. Dosch[1]. 1) University Of Goettingen, Goettingen, Niedersachsen, DE; 2) University of Geneva Genève, GE, Switzerland.

The germline is vital for the continuation of a species. Many animals specify their germ cells by deposition of a maternal RNA granule termed germ plasm. The inheritance of germ plasm by an embryonic cell initiates its development into a primordial germ cell. To this end, two proteins are known in animals which program germ cell development *in vivo*: Oskar, which is specific to insects and Bucky ball (Buc), which we discovered in vertebrates. These two proteins are termed germ plasm organizers because their loss of function results in the failure to form germ plasm.

We discovered in the zebrafish embryo that both germ plasm organizers possess the fascinating ability to transform a somatic cell into a primordial germ cell. This result indicates that both proteins act through a conserved biochemical network to specify the germ cell fate. Comparing the amino acid sequence of the two organizers, we found that *Drosophila* Oskar and Zebrafish Bucky Ball showed no conserved domains to explain their similar function. To shed light on the biochemical interaction network of Bucky ball, we carried out co-immunoprecipitation experiments. We found that Buc interacts *in-vivo* with the canonical germ plasm factor Vasa as described for Oskar.

To explain the deviation from the traditional structure-function paradigm by the two proteins, we discovered that both encode intrinsically disordered proteins (IDP). As IDPs quickly change their sequence during evolution, we propose that Buc is an Oskar homolog, which exerts its conserved role through similar biophysical properties. In summary, these data describe the first example of proteins, which were previously classified as "novel" or "species-specific", but which are indeed functional homologs from distant species.

Z544 *Fibroblast growth factor 24* is required for early somatic gonad development in zebrafish. *D. M. Leerberg*[1], K. Sano[2], B. W. Draper[1]. 1) University of California, Davis, Davis, CA; 2) 2Department of Materials and Life Sciences, Sophia University, Tokyo, Japan.

The vertebrate gonad consists of two cell populations: germ cells (GCs), which produce the gametes, and somatic gonad cells (SGCs), which serve two important functions. First, SGCs create an environment that protects GCs and nurtures their development through cell signaling. Second, a subset of SGCs secrete hormones required for secondary sexual development, and therefore defects in SGC development result in disorders of sexual development. Despite the known importance of SGCs for fertility, little is known how the early somatic gonad forms or which genes are required for its formation. We have discovered that a mutation in the zebrafish Fibroblast growth factor (Fgf) ligand *fgf24* results in a reduction of GCs during larval development, at a time that precedes sexual differentiation. The phenotype persists into adulthood, and most mutant adults are sterile. Upon examination of the 10 days post fertilization (dpf) gonad by transmission electron microscopy (TEM), we found that wild-type fish have multilayered gonads, where the SGCs have already begun to separate into two distinct layers and the GCs are arranged in the center, protected by the SGCs. We have determined that *fgf24* is expressed in the outer layer of epithelial-like SGCs. In contrast, a known Fgf-responsive gene, *ets variant 4* (*etv4/pea3*), is expressed in the population of mesenchymal-like SGCs more internally located. Based on the TEM data and Laminin immunostaining, we have found that these layers are separated by a basement membrane. In contrast, the gonads of *fgf24* mutants have only one layer of SGCs enveloping the GCs, lack a basement membrane, and fail to express *etv4*. Furthermore, we asked whether genes known to be important for SGC function were expressed in *fgf24* mutants: *gata4*, a transcription factor required for mouse gonadogenesis; *cyp19a1a*, an aromatase that converts androgens to estrogens; and *amh*, a TGF-β ligand required for male sexual development in many vertebrates. In accordance with our hypothesis, *in situ* hybridization showed that these genes were expressed in the mesenchymal SGC population of wild-type larval fish, but their expression was greatly reduced or completely absent in *fgf24* mutant gonads. These results support our overall hypothesis that Fgf24 functions primarily to promote development of the mesenchymal SGCs and overall morphogenesis of the somatic gonad, and that the loss of GCs in *fgf24* mutants is a secondary consequence of a somatic gonad defect.

Z545 Wnt signaling regulates progenitor cell identity and collective cell migration in the lateral line. *H. F. McGraw*[1], A. Forbes[1], Y. Xie[2], R. I. Dorsky[2], A. V. Nechiporuk[1]. 1) Oregon Health & Science University, Portland, OR; 2) University of Utah, Salt Lake City, UT.

Collective cell migration, which is movement of cells as a cohesive group, is a critical process during embryonic organ formation, wound healing and is inappropriately coopted during the invasion of certain cancers. Although many of the cellular hallmarks of collective cell migration have been defined, the genetic pathways that regulate these processes are not well understood. Development of the zebrafish lateral line has proven to be an elegant model for studying collective cell migration, as it is amenable to live imaging and genetic manipulation. The posterior lateral line (pLL) forms from the posterior lateral line primordium (pLLP), a cohort of ~100 cells which collectively migrate along the trunk of the developing zebrafish embryo. The pLLP is comprised of proliferative progenitor cells and organized epithelial cells that will form the hair cell-containing mechanosensory organs of the pLL. Wnt signaling is active in the leading progenitor zone of the pLLP and regulates cellular proliferation, survival and maintenance. Here we examine the downstream targets of Wnt signaling and their role in mediating pLLP progenitor cell behavior. We used RNA-sequencing to identify genes that are altered in zebrafish embryos carrying mutations in members of the canonical Wnt pathway that are known to regulate pLL formation, i.e. *lef1* and *kremen1*, as compared to wild-type controls. One of the genes we selected for further analysis is the tumor suppressor Fat1b, which is strongly expressed in the wild-type pLLP and is downregulated following loss of Wnt signaling. CRISPR-Cas9-mediated mutation of Fat1b function results in failed pLLP migration in a manner that is similar to previously described canonical Wnt signaling mutants. These data suggest that our approach will allow us to refine our understanding of how canonical Wnt signaling pathway regulates various cellular behaviors.

Z546 Migratory neural crest is required for patterning and morphogenesis of the embryonic optic cup. *C. D. Bryan*, K. M. Kwan. University of Utah, Salt Lake City, UT.

Extrinsic, migratory mesenchymal cells are essential for the development and morphogenesis of many epithelial organs. In mouse, early eye defects have been described in a neural crest mutant, but the cellular and molecular mechanisms underlying aberrant optic cup morphology and patterning are unknown. Using zebrafish molecular genetics and multidimensional timelapse imaging, we sought to determine when and how neural crest migrates around the early eye, as well as exactly when and how eye defects arise in the absence of neural crest.

We find that at the earliest stages of optic vesicle formation, sox10-positive neural crest cells are in direct contact with the dorsal, posterior optic vesicle; these neural crest cells then migrate ventrally and anteriorly to enwrap the developing optic cup. By the end of optic cup morphogenesis, neural crest derived cells encapsulate the optic stalk and all but the distal, lens-facing side of the optic cup. Therefore, neural crest is present at the right time and place to influence patterning and morphogenesis of specific regions of the developing eye.

To determine precisely when and where eye defects arise in the absence of neural crest, we utilize the zebrafish *tfap2a*^{ts213}*;foxd3*^{zdf10} double mutant which exhibits a complete loss of neural crest. In the absence of neural crest, we find dramatic optic cup morphogenesis defects including a misshapen retina and coloboma, suggesting that neural crest is required for optic cup invagination and formation of the optic fissure. Similar results were seen using an independent neural crest mutant (*paf1*^{z24}). In addition to the morphological defects, we began to characterize defects in tissue patterning: as in mouse *Tcfap2a* knockouts, *tfap2a;foxd3* mutant zebrafish display an aberrant expansion of Pax2a expression into ectopic dorsal and posterior domains. This suggests an evolutionarily conserved role for neural crest in optic stalk and optic cup patterning and control of morphogenetic movements critical for optic cup formation.

Using computational cell tracking tools combined with our multidimensional imaging datasets, we are now pinpointing the precise cell

movements disrupted by loss of neural crest as well as examining the specific signaling pathways dysregulated in the absence of neural crest. These results highlight the diverse roles mesenchyme can play in epithelial organ development and morphogenesis.

Z547 Neuronal connectivity analysis of wild-type and mutant zebrafish with transsynaptic virus and 3D brain mapping. *Manxiu Michelle Ma*[1], Owen Randlett[2], Stanislav Kler[1], Kristin Ates[1,3], Avirale Sharma[1], Tong Wang[1], Constance Cepko[4,5], Florian Engert[2], Alexander F. Schier[2], Yuchin Albert Pan[1,6]. 1) Department of Neuroscience and Regenerative Medicine, Medical College of Georgia, Augusta University, Augusta, GA; 2) Department of Molecular and Cellular Biology, Center for Brain Science, Harvard University, Cambridge, MA; 3) MD/PhD Program and Graduate Program in Neuroscience; 4) Howard Hughes Medical Institute; 5) Department of Genetics, Harvard Medical School, Boston, MA; 6) Department of Neurology and James & Jean Culver Vision Discovery Institute, Medical College of Georgia, Augusta University, Augusta, GA.

The unique combination of small size, translucent brain, and powerful genetics makes zebrafish an ideal vertebrate model system to investigate normal and pathological brain functions. However, it remains challenging to map out the myriad of connections between neurons and identify cellular level connectivity changes during development or disease. We recently found that vesicular stomatitis virus (VSV) can effectively infect zebrafish neurons and label connected neurons, paving the way for rapid brain mapping (J Comp Neurol. 2015; 523:1639-63). In this study, we combined multiple types of recombinant transsynaptic VSV, neurotransmitter phenotyping, and semi-automated 3D brain mapping to analyze the connectivity patterns between the retina and the brain in wild-type and mutant zebrafish. In wild-type fish, we observed VSV labeled retinorecipient cells near the visual afferent terminals in the diencephalon and the optic tectum, consistent with previous studies. Next, we analyzed zebrafish mutants of dscaml1, a conserved neuronal transmembrane molecule implicated in human autism spectrum disorder. dscaml1 homozygous mutants show greatly reduced connections, and the decrease is non-uniform among different brain regions. The reduced connectivity to the optic tectum, a critical region for saccade generation, may contribute to the reduced saccadic eye movements observed in mutants. Together, these results suggest novel roles for dscaml1 in establishing neuronal connectivity and visual behaviors. This approach will likely be useful for neuronal connectivity analysis in other zebrafish mutants or disease models.

Z548 Assembling the MET complex in sensory hair cells: Tomt regulates the trafficking of Tmc proteins to the site of mechanotransduction. *Timothy Erickson*[1], Elisabeth Busch-Nentwich[2], Jennifer Olt[3], Katherine Hardy[3], Reo Maeda[1], Rachel Clemens-Grisham[1], Alex Nechiporuk[1], Walter Marcotti[3], Teresa Nicolson[1]. 1) Oregon Health and Science University, Portland, OR; 2) Wellcome Trust Sanger Institute, Cambridge, UK; 3) University of Sheffield, Sheffield, UK.

The mechanoelectrical transduction (MET) complex is a multimeric transmembrane protein assembly that allows sensory hair cells to convert mechanical stimuli into electrical signals. Members of the complex include the tip link proteins PCDH15 and CDH23, as well as MET channel subunits LHFPL5, TMIE and TMC1 / 2. Although the identity of the ion channel that mediates MET is controversial, genetic and molecular evidence shows that Transmembrane channel-like proteins (TMC1 and TMC2) play an essential role in the MET complex, possibly acting as the pore-forming subunits of the channel. How the TMCs and other MET proteins assemble into a functional unit is a major outstanding question in the field of hearing research.

Transmembrane O-methyltransferase (*TOMT* / *LRTOMT*) is a human deafness gene responsible for non-syndromic deafness DFNB63. However, the specific role that TOMT plays in hair cells is not known. We found the zebrafish ortholog of *tomt* (*mercury*) in a mutagenesis screen for deafness and balance mutants in zebrafish. Tomt-deficient hair cells have normal morphology, but do not have functional mechanotransduction. GFP-tagged Tomt is enriched in the Golgi, and excluded from the site of MET in the apical hair bundle of hair cells. Since Tomt is not a part of the MET complex itself, we reasoned that it functions in the Golgi to regulate the trafficking of other MET components to the hair bundle. Tomt is not required for the normal trafficking of Pcdh15a, Lhfpl5a, or Tmie. However, we found that GFP-tagged Tmc1 and Tmc2b proteins are specifically excluded from the hair bundle in Tomt mutants. Transgenic expression of Tomt is sufficient to restore MET to mutant hair cells, and to restore Tmc localization in the hair bundle. Thus, we propose a model of MET complex assembly where Tomt methyltransferase activity is required for the correct trafficking of Tmc proteins in sensory hair cells.

Z549 Asymmetric activation of the dorsal habenulae correlates with larval recovery from electric shock. *E. R. Duboué*[1], E. Hong[2], A. Muto[3,4], K. Kawakami[3,4], M. E. Halpern[1]. 1) Carnegie Institution for Science, Baltimore, MD; 2) Laboratoire Neurosciences Paris Seine, INSERM UMRS 1130, UMR 8246 Université Pierre et Marie Curie 75252 Paris, France; 3) Division of Molecular and Developmental Biology, National Institute of Genetics, Mishima, Shizuoka, Japan; 4) Department of Genetics, The Graduate University for Advanced Studies (SOKENDAI) Mishima, Shizuoka, Japan.

Owing to their differences in size, gene expression and connectivity, the dorsal habenulae (dHb) of larval zebrafish can be used to assess the significance of left-right (L-R) asymmetry of the brain on behavior. In particular, we discovered a differential response between the left and right dHb to a fearful stimulus, mild electric shock. Following shock, wild-type larvae freeze for a short period of time (10-15 sec) before swimming again. Whole body cortisol levels, as measured in groups of larvae, also increase in response to electrical stimulation. Optogenetic activation of the dHb decreases the length of freezing, indicating that this brain region expedites the recovery from an aversive stimulus. Using *in vivo* calcium imaging in head affixed larvae, we identified an asymmetric population of neurons, whose activation is temporally correlated with recovery from shock. Consistent with more neurons in the left dHb modulating the response, unilateral severing of a major axonal pathway from the left but not the right dHb results in increased freezing behavior. Larvae with L-R reversed asymmetry or with right isomerized dHb also show a significant increase in freezing duration, as well as higher cortisol levels compared to controls. Moreover, neural activation in response to shock is not detected in the dHb by calcium imaging of these larvae. By contrast, larvae with left isomerized dHb exhibit a similar

period of freezing as their wild-type siblings but an equivalent number of neurons are activated in both dHb. The data suggest that a neuronal population, which predominates in the left dHb, mediates fear responses in larval zebrafish.

Z550 Linking function to cell type in the optic flow responsive circuit in zebrafish larva. *A. Kramer*, D. Förster, H. Baier, F. Kubo. Max Planck Inst. of Neurobiology, Martinsried, DE.

The accessory optic system (AOS) integrates binocular visual information to drive compensatory eye and body movements in response to optic flow. Recently, we showed, by optical imaging in the AOS homolog of larval zebrafish, the pretectal area, the existence of different types of direction-selective (DS) neurons (Kubo *et al*., 2014). So-called "simple cells" responded to moving gratings presented to one or two eyes, either nasal- or temporalward, or a combination of these stimuli. "Complex cells", on the other hand, encoded either translational or rotational motion. Simple responses can be generated by feedforward monocular DS inputs (e. g. from retinal ganglion cells). Complex response types, however, combine information from both eyes, requiring DS inhibitory connections. From this analysis, Kubo *et al*. (2014) were able to predict a wiring diagram of the optic-flow responsive circuit.

To test the predictions, we established a novel optogenetic method, combining functional characterization with morphological analysis of individual cells. In FuGiMA (Function-guided inducible morphological analysis), a cell of a specific response type is identified by regressor-based correlation of *in vivo* GCaMP6s imaging data with the expected neuronal activity. Next, paGFP is activated in the identified cell, enabling the visualization of its morphology.

We successfully reconstructed neurons with simple and complex response types. Registering the cells to a reference brain, we are now exploring if cells of the same response type have similar projection patterns. In parallel, we are also mapping inhibitory and excitatory cells in the pretectal area.

Z551 A forward genetic screen identifies the G-protein coupled calcium receptor CaSR as a regulator of simple decision-making. *R. A. Jain*[1], M. Wolman[2], K. Marsden[3], J. Nelson[3], H. Shoenhard[3], H. Bell[3], J. Skinner[3], M. Granato[3]. 1) Haverford College, Haverford, PA; 2) U Wisconsin-Madison, Madison, WI; 3) U Pennsylvania, Philadelphia, PA.

Animals appropriately respond to their constantly shifting environment through the critical process of decision-making: the selection of one behavioral response from a set of alternatives, each expected to produce different outcomes. While decision-making can involve complex cognitive processing, even simple responses can be dynamically biased and modulated, representing a more tractable system to study the underlying genetic and cellular decision-making mechanisms.

We have developed a simple decision-making paradigm in larval zebrafish using the evolutionarily conserved acoustic startle response. Larvae respond to acoustic stimuli with one of 2 kinematically, neuronally, and genetically distinct behaviors: a Short-Latency C-bend (SLC) initiated 4-15 ms post-stimulus, or a less vigorous Long-Latency C-bend (LLC) initiated 20-80 ms post-stimulus. Individual larvae can respond to acoustic stimuli with either behavior, yet bias their responses toward SLCs following intense stimuli and toward LLCs following weak stimuli. Importantly, individuals incorporate prior experience in selecting their behavioral output, shifting their response bias from SLCs to LLCs following repeated identical strong stimuli. Thus, the basic dynamic aspects of complex cognitive decision-making are present in this simple SLC/LLC decision-making paradigm.

To identify genes and pathways critical for the development and function of startle decision circuits, we performed a small molecule screen and a forward genetic screen. The small molecule screen results demonstrate that as in more complex cognitive assays, serotonergic modulation through the 5-HT1A receptor is critical for acoustic decision-making. Through our forward genetic screen we identified 10 mutants with specific defects in SLC/LLC bias, the first vertebrate mutants specifically isolated based solely on decision-making deficits. Using whole-genome sequencing we have identified mutations in both the *calcium-sensing receptor* (*CaSR*) gene and a regulator of CaSR endocytosis that both modify decision-making behavior. Furthermore, we have demonstrated an acute role for CaSR during decision-making and have identified the G-protein signaling pathways regulating appropriate bias through specific signaling agonists and antagonists. Finally, we have identified changes in the activity of key circuit components underlying these decision-making alterations through functional neural imaging to elucidate how serotonergic signaling and *CaSR* gene function influence simple decision-making.

Z552 Feeding state modulates behavioral choice and processing of prey stimuli in the zebrafish tectum. *Alessandro Filosa*, Alison Barker, Marco Dal Maschio, Herwig Baier. MPI of Neurobiology, Martinsried, DE.

Animals scan their visual environment to respond to threats and locate food sources. The neural computations underlying the selection of a particular behavior, such as escape or approach, require flexibility to balance potential cost and benefit to the animal's survival. For example, avoidance of a visual object reduces predation risk, but negatively affects foraging success. Zebrafish larvae approach small, moving dots ('prey') and avoid large, looming dots ('predator'). We found that this binary classification of objects by size is strongly influenced by feeding state. Changes in behavior correlate with shifts in neuronal responses to prey cues in the optic tectum. Both behavior and tectal function are modulated by signals from the hypothalamic-pituitary-interrenal axis and the serotonergic system. Our study has revealed a neuroendocrine mechanism by which the motivation to eat influences the perception of food in a vertebrate visual system.

Z553 Impact of circadian protein Period2 on glucocorticoid signaling and depression regulation. *Mingyong Wang*[1,2], Han Wang[1,2]. 1) Center for Circadian Clocks, Soochow University, Suzhou 215123, Jiangsu, China; 2) School of Biology & Basic Medical Sciences, Medical College, Soochow University, Suzhou 215123, Jiangsu, China.

The circadian clock as an endogenous time-keeping mechanism modulates fundamental life processes from molecular, biochemical, cellular, physiological to behaviorial with a period of approximately 24 hours. Previous studies showed that circadian abnormalities often lead to human moody disorders. However, little is known about any role of circadian protein Period2 (Per2) in depression pathogenesis. Here a series of behavioral assays show that TALEN-generated zebrafish *per2* mutant fish display lower locomotor activities, more time staying in the center region of the tank and less time for social interaction, in comparison with wild types, indicating a clear depression phenotype of the *per2* mutant zebrafish. Quantitative RT-PCR showed that glucocorticoid receptor (*gr*) is significantly down-regulated in both the *per2* mutant larvae and adult male fish brain. Luciferase reporter assays showed that Per2 can enhance Rorα-mediated expression of *gr*, and ChIP assays showed that Per2 binds to the three RORE elements in the *gr* promoter, suggesting that Per2 positively regulates *gr* in zebrafish. Further, cortisol, and expression of *pomc*(*proopiomelanocortin*) and *crh* (*corticotropin releasing hormone*) are significantly up-regulated in the *per2* mutant male fish, implicating disruptive activities of the hypothalamic-pituitary-adrenal (HPA) axis of the *per2* mutant fish. Taken together, our findings demonstrate that Per2 acts through glucocorticoid receptor signaling to impact activities of the hypothalamic-pituitary-adrenal (HPA) axis and to contribute to depression pathogenesis, shed light on a novel circadian role in moody disorders.

Z554 Visualizing Inhibitory Structural Synaptic Plasticity During Day and Night. *I. Elbaz*[1], D. Zada[1], A. Tovin[1], T. Tsur[1], T. Lerer-Goldshtein[1], G. Wang[2], P. Mourrain[2,3], L. Appelbaum[1]. 1) Bar-Ilan University, Ramat-Gan, IL; 2) Stanford University, Palo Alto, CA; 3) Ecole Normale Supérieure Paris, France.

Sleep is tightly regulated by the circadian clock and homeostatic mechanisms. The function of sleep is debated although it is established that the sleep/wake cycle is associated with structural and physiological synaptic changes that benefit the brain. Continuous imaging of single neuronal circuits in live animal is vital to understand the role of sleep in regulating synaptic dynamics. The hypothalamic hypocretin/orexin (Hcrt) neurons regulate various functions including feeding, reward, sleep and wake. In the zebrafish model, few Hcrt neurons regulate sleep and wake, and its transparency enables time-lapse imaging of single synapses during both day and night. Here, we established the Gephyrin (Gphn) protein, a central inhibitory synapse organizer, as a fluorescent post-synaptic marker of inhibitory synapses. A transgenic zebrafish that expresses the fusion protein Gphn-EGFP in specific neurons of interest was generated. Double labeling showed that Gphn-tagRFP and Collybistin-EGFP clusters co-localized in dendritic inhibitory synapses. In the dendrites of Hcrt neurons, inhibitory synapse number is increased during development and is stabilized at 6 days post fertilization (dpf). To determine the effect of sleep on inhibitory synapse number, we performed two-photon live imaging of Gphn-EGFP clusters in Hcrt neurons during day and night, under light/dark and constant light and dark conditions, and following sleep deprivation. We found that synapse number is increased during the night and decreased during the day. These changes in synaptic number are eliminated under constant conditions and in sleep-deprived larvae. These results suggest that rhythmic structural plasticity of inhibitory synapses in Hcrt dendrites is independent of the circadian clock and is regulated by sleep pressure.

Z555 Identifying novel regulators of early cardiac development in zebrafish using single-cell mRNA-seq and ATAC-seq. *X. Yuan*[1,2], M. Song[3], A. Aleksandrova[1], W. Devine[4], B. Bruneau[4,5], M. Wilson*[1,2], I. Scott*[1,2], *co-corresponding authors. 1) The Hospital for Sick Children, Toronto, ON, Canada; 2) University of Toronto, Toronto, ON,Canada; 3) Peking University, Beijing, China; 4) Gladstone Institute, San Francisco, CA, USA; 5) UCSF, San Francisco, CA, USA.

Heart disease remains a leading cause of death worldwide. A comprehensive understanding of the mechanisms underlying heart formation is crucial for uncovering causes of congenital heart disease and developing regenerative therapies. However there is currently a lack of markers that will enhance our understanding of the very earliest steps of vertebrate heart development, prior to the onset of *nkx2.5* expression in the cardiac crescent. Recently a mouse enhancer (*Smarcd3*-F6) was shown to label cardiac progenitor cells (CPCs) *in vivo*. Here we asked whether this mouse *Smarcd3*-F6 enhancer could serve as an early CPC marker in zebrafish. We created a stable zebrafish *Smarcd3-F6:EGFP* transgenic line and characterized the labeled population using immunostaining, RNA-seq and ATAC-seq (genome-wide profiling of open chromatins). The *Smarcd3*-F6 enhancer was active at early gastrula stage and enriched for CPCs. Despite sharing no sequence conservation with zebrafish, *Smarcd3-F6:EGFP* activity required the cardiac master regulator Gata5. Both RNA-seq and ATAC-seq results showed cardiac development-related pathways were enriched in *Smarcd3-F6:EGFP* labeled cells. Several ATAC-seq peaks near known cardiac genes drove early cardiac expression when tested in embryos, suggesting they could be novel markers facilitating early cardiac development studies. In order to further dissect the *Smarcd3*-F6+ cell population, we conducted single-cell mRNA-seq and identified a cluster of cells co-expressing known cardiac markers at the end of gastrulation, which represented the potential CPC lineage. Using *in situ* hybridization we have tested the expression of over 20 novel genes identified from the single-cell cardiac cluster and confirmed the vast majority of them showed early expression in the cardiac domain of zebrafish embryos. Currently we are performing single-cell mRNA-seq at multiple time points during gastrulation to assess the dynamics of CPC development. On-going experiments will also characterize the roles the novel genes play in cardiac development via CRISPR/Cas9 mutagenesis. In addition to improving our understanding of early cardiac gene regulation in zebrafish, our work underscores the conserved regulatory logic of vertebrate heart development.

Z556 PDGF signaling directs cardiomyocyte movement toward the midline during heart tube assembly. *D. Yelon*, J. Bloomekatz, A. C. Dunn, M. Vaughan. University of California, San Diego, La Jolla, CA.

Communication between neighboring tissues plays a central role in directing cell movement during organ morphogenesis. Heart tube assembly, for example, begins with the movement of bilateral populations of cardiomyocytes toward the midline, where they merge together in a process called cardiac fusion. Prior studies have established that cardiac fusion is regulated by interactions between the lateral plate mesoderm and the adjacent endoderm, but the molecular underpinnings of the relationship between these tissues remain unclear. Here, we reveal a new role for platelet-derived growth factor (PDGF) signaling in mediating tissue communication during heart tube assembly. We find that mutation of the zebrafish *pdgfra* gene, encoding PDGF receptor alpha, causes cardia bifida, a failure of cardiac fusion. Cell tracking experiments demonstrate that this defect is the consequence of misdirected cell movements, indicating a specific role of PDGF signaling in guiding cardiomyocytes toward the midline. Intriguingly, the PDGF ligand gene *pdgfaa* is expressed within a portion of the endoderm that is positioned just medial to the *pdgfra*-expressing lateral plate mesoderm. Overexpression of *pdgfaa* throughout the embryo interferes with cardiac fusion, revealing an instructive role for PDGF signaling during this process. Together, our data suggest a novel mechanism through which endodermal-myocardial communication directs the stereotyped patterns of cell movement that initiate cardiac morphogenesis.

Z557 Convergence of FGF and Nodal signals on the actin cytoskeleton controls cardiac cell migration in zebrafish. *M. Grant*, J. Rowland-Williams, D. Grimes, R. D. Burdine. Princeton University, Princeton, NJ.

Nearly 40,000 infants are born each year with Congenital Heart Defects, structural abnormalities arising from aberrant asymmetric heart development. As formation of the zebrafish heart also relies upon proper asymmetric morphogenesis, we use these organisms as a model to understand the necessary signals and cellular events that underlie this process. In zebrafish, the first asymmetric event in the heart, cardiac jogging, results in the repositioning of atrial precursors to the left and anterior of ventricular precursors. The process of jogging occurs simultaneously with the conversion of a structure called the cardiac cone into a linear heart tube. We previously discovered that the Nodal signaling pathway contributes to the asymmetry of the zebrafish heart tube by increasing the velocities of cells on the left of the cardiac cone.

Microarray analysis on isolated cardiac cells reveals upregulation of regulators of the actin cytoskeleton, FGF receptors, and FGF transcriptional targets in the heart in response to Nodal during jogging. In our preliminary data, we find evidence of the convergence of the Nodal and Fibroblast Growth Factor (FGF) pathways on the actin cytoskeleton. We also find that reduction of actin polymerization or FGF signaling mimic loss of nodal: under these conditions, tube formation is disrupted and tube extension is perturbed. Time-lapse confocal microscopy reveals a significant decrease in cell migration rates in embryos in which FGFR signaling or actin polymerization is reduced. Finally, epistasis analysis suggests that FGFR signaling functions parallel to Nodal to affect cell migration. Thus, we propose that FGFR signaling acts as a general pro-migratory signal for cardiac cells and cooperates with Nodal, which exerts an asymmetric motogenic effect on cardiac precursors by acting on the cytoskeleton.

Z558 Cardiomyocyte fusion in zabrafish. *S. Sawamiphak*, Z. Kontarakis, S. Reischauer, D. Stainier. MPI Heart and Lung Research, Bad Nauheim, DE.

Cells can sacrifice their individuality and fuse to acquire specialized functions. The generation of multinucleated syncytia in the developing skeletal myocytes by cell fusion is thought to be essential for effective contractility. However, the prevalence and significance of cell fusion in different tissues under developmental or physiological conditions is not well described. Here, we introduce a transgenic zebrafish reporter line that allows fluorescent labeling of polyploid cells. Surprisingly, besides skeletal muscles, some cardiomyocytes turn on the fluorescent reporter. This cell population largely contributes to the proliferating cardiomyocytes at this stage. Therefore, we hypothesized that, rather than cytokinesis failure, membrane fusion is the mechanism that activates the polyploidy reporter in these cells. Correspondingly, we observed a reduction of polyploidy reporter-activated cardiomyocytes in the cell fusion-compromised *jam3b* mutants, accompanied by a decrease in cardiomyocyte proliferation. Regenerative response of injured adult heart, conversely, increases polyploidy reporter-activated cells. Furthermore, blastula transplantations show a significant number of cardiomyocytes that harbor both donor- and host-derived transgenes, further suggesting the occurrence of cardiomyocyte fusion in the larval heart. Together, our findings not only uncover a novel cellular process occurring in the developing heart, but also highlight its possible role in cardiomyocyte proliferation in the vertebrate heart.

Z559 HDAC1 repression of retinoic acid-responsive genes promotes second heart field development. *Y. Song*[1,2], A. Rydeen[1,2], T. Dohn[1,2], J. Waxman[2]. 1) University of Cincinnati, Cincinnati, OH; 2) Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Outflow tract (OFT) defects make up a significant portion of congenital heart defects (CHDs), the most common birth malformations. The vertebrate OFT is derived from later differentiating second heart field (SHF) progenitors, necessitating a greater understanding of the mechanisms directing proper SHF development. In a screen for effectors of heart development, we identified the *cardiac really gone* (*crg)* mutant, which displays a smaller OFT and reduced ventricular cardiomyocytes. Furthermore, we observe a loss of SHF marker gene expression after cardiac differentiation occurs from the earlier differentiating first heart field, suggesting that SHF development is specifically affected in *crg* mutants. Positional cloning of *crg* revealed that it is a novel *histone deacetylase 1* (*hdac1)* mutant allele, with a mutation in a nucleotide of the splice donor site for the 7th exon. Consistent with HDAC1 being required to promote SHF addition, embryos treated with the HDAC inhibitor trichostatin A (TSA) or depleted for HDAC1 with morpholinos also display a similar specific loss of ventricular cardiomyocytes and SHF progenitor markers. Interestingly, the specific effects on SHF development are similar to what we have recently found in Cyp26 deficient embryos, which have an increase in retinoic acid (RA) levels. Although HDACs are known to interact with RA receptors (RARs), there are few

examples of RARs being required to mediate transcriptional repression during development. Hence, we performed RNA-seq on *crg* and Cyp26 deficient embryos and identified that the expression of *ripply3*, a transcriptional co-repressor of TBX transcription factors, is similarly increased in the hearts of both conditions, suggesting that HDAC1-mediated repression of ripply3 may be necessary for SHF development. Consistent with this hypothesis, we find that overexpression of Ripply3 can restrict cardiac development. Altogether, our study reveals a novel mechanism whereby the epigenetic regulator HDAC1 promotes SHF development through repressing the expression of the RA-responsive gene *ripply3*.

Z560 Epigenetic control of zebrafish cardiogenesis by TET2/3. *Y. Lan*[1], C. Li[1,2], M. Goll[2], T. Evans[1]. 1) Weill Cornell Medical College, New York, NY; 2) Memorial Sloan Kettering Cancer Center, New York, NY.

The targeted addition and removal of DNA methylation marks are major epigenetic regulatory mechanisms essential for normal development. Ten-eleven translocation (TET) enzymes (TET1/2/3) mediate methylcytosine (5mC) hydroxylation, which can facilitate DNA demethylation and altered gene expression. Functions for TET enzymes during development of complex organs including the heart have not been explored. Using zebrafish strains with targeted mutations in TET genes, we identified Tet2 and Tet3 as the major 5mC dioxygenases during zebrafish embryogenesis and observed specific defects in cardiogenesis in tet2/3$^{-/-}$ double mutant larvae. Morphological, molecular, and reporter strain analyses indicate defects in both epicardium migration and atrioventricular canal (AVC) development in tet2/3$^{-/-}$ double mutants. Co-culture experiments suggest that the epicardial defect may be indirectly caused by an altered myocardial program. To investigate the molecular mechanism, we compared transcript profiles of embryonic hearts isolated from wild type or double mutant embryos, and identified several candidate pathways that could impact epicardial and AVC development. Genome-wide MeDIP-seq and hMeDIP-seq experiments are ongoing to correlate DNA methylation and gene expression changes between mutant and wild types. This analysis should elucidate for the first time essential DNA epigenetic modifications that govern gene expression changes during cardiac development.

Z561 Multicolor mapping of the cardiomyocyte proliferation dynamics that construct the atrium. *M. J. Foglia*, J. Cao, V. A. Tornini, K. D. Poss. Duke University Medical Center, Durham, NC.

The orchestrated division of cardiomyocytes assembles heart chambers of distinct morphology. To understand the structural divergence of the cardiac chambers, we determined the contributions of individual embryonic cardiomyocytes to the atrium in zebrafish by multicolor fate-mapping, and we compare our analysis to the established proliferation dynamics of ventricular cardiomyocytes. We find that most atrial cardiomyocytes become rod-shaped in the second week of life, generating a single-muscle-cell-thick myocardial wall with a striking webbed morphology. Inner pectinate myofibers form mainly by direct branching, unlike delamination events that create ventricular trabeculae. Thus muscle clones assembling the atrial chamber can extend from wall to lumen. As zebrafish mature, atrial wall cardiomyocytes proliferate laterally to generate cohesive patches of diverse shapes and sizes, frequently with dominant clones that comprise 20-30% of the wall area. A subpopulation of cardiomyocytes that transiently express amhc (myh6) contributes substantially to specific regions of the ventricle, suggesting an unappreciated level of plasticity during chamber formation. Our findings reveal proliferation dynamics and fate decisions of cardiomyocytes that produce the distinct architecture of the atrium.

Z562 Spatiotemporal regulation of cell size and nuclear content during regeneration of the epicardium. *Jingli Cao*, Jinhu Wang, Kenneth Poss. Duke University, Durham, NC.

Adult zebrafish possess a remarkable capacity for cardiac regeneration without significant scarring. The epicardium, a mesothelial cell layer enveloping the heart, is activated by cardiac injury and enables new muscle regeneration through paracrine effects and as a multipotent cell source. Recent work revealed that the epicardium is highly regenerative, and that its presence is required for muscle regeneration. Yet, the cellular and molecular mechanisms by which epicardial cells respond to cardiac injury require elucidation. In this study, we created a panel of transgenic lines employing *tcf21* regulatory sequences to visualize subcellular components (LifeAct-EGFP, Histone H2A-EGFP) and cell cycle phases (FUCCI) within epicardial cells. Combining these reagents with an *ex vivo* system for live imaging of epicardial regeneration, we found that endoreplication and hypertrophy are prominent in cells at the leading edge of the regenerating epicardial sheet. By contrast, epicardial cells in the lagging regions complete cytokinesis and are responsible for increased cell density. Endoreplication (including both endocycling and endomitosis), but not cell fusion, leads to hypertrophic epicardial cells. These cells are further eliminated through apoptosis after full recovery of the ventricular epicardium. Through chemical screening we found that inhibition of Tgf-beta signaling blocked epicardial cell proliferation, led to smaller numbers of cells and higher incidence of hypertrophy, suggesting a key role in balancing sheet dynamics. Our findings indicate an unexpected role for endoreplication and hypertrophy in regeneration of the cardiac mesothelium.

Z563 The zebrafish embryo mRNA interactome reveals distinct roles for hnRNP A1 during the maternal to zygotic transition. *K. Neugebauer*, V. Despic. Yale, New Haven, CT.

In all metazoans, early embryogenesis is driven by maternal RNAs until zygotic transcription begins several hours later. During this maternal-to-zygotic transition (MZT), mRNA translation and stability regulation is essential. Thus, early embryogenesis is governed entirely by RNA biology; yet the RNA-binding proteins (RBPs) that interact with RNA are largely unknown. Here we identify 223 mRNA-bound proteins (mRBPs) in zebrafish embryos before and during zygotic transcriptional onset, including a subset of stage- and species-specific mRBPs. We show that hnRNP A1, an abundant component of the interactome, exhibits unusual 3'UTR binding. This is surprising, because hnRNPs bind mostly to introns in somatic cells. Furthermore, hnRNP A1 associated with zygotic m6A modified pri-miR430 transcripts, implicating hnRNP A1 in the

biogenesis of miR430, which is essential for maternal mRNA degradation during MZT. Our study uncovers core regulators of embryonic RNA and suggests that hnRNP proteins adopt unconventional RNA processing roles to promote vertebrate development.

Z564 Clearance of maternal mRNAs via 3'-end uridylation in vertebrate embryos. *Hyeshik Chang*[1,2], Jinah Yeo[1,2], Jeong-gyun Kim[2], Hyunjoon Kim[1,2], Jaechul Lim[1,2], Hee-Yeon Jeon[2], Hyun Ho Kim[2], Jiyeon Ok[3], Hosung Jung[3], Hyunsook Lee[2], Kyuwon Kim[2], V. Narry Kim[1,2]. 1) Institute for Basic Science, Seoul, KR; 2) Seoul National Univ., Seoul, KR; 3) Yonsei Univ., Seoul, KR.

During the maternal-to-zygotic transition (MZT), maternal transcriptome should be degraded, and replaced by zygotic transcripts in a highly coordinated manner. As transcription is silenced in early stages, transcriptome is regulated by cytoplasmic polyadenylation and RNA decay. We recently developed a new high-throughput sequencing technique, coined TAIL-seq, that profiles the poly(A) length and 3'-end modifications. TAIL-seq enables us to monitor the dynamics of adenylation, deadenylation and nucleotide tagging to the 3'-end of maternal RNAs with single-nucleotide resolution at genomic scale.

In this study, we apply TAIL-seq to early stage embryos of zebrafish to reveal how the RNA regulatory mechanisms influence the transcriptome. Our data confirm that poly(A) tails of most mRNAs elongate shortly after fertilization until the middle of the MZT, while a smaller group of transcripts escapes from this regulation. Surprisingly, most maternal RNAs acquire U tails in addition to poly(A) tails during the MZT. This phenomenon is observed in mouse and *Xenopus laevis* embryos, as well.

We identify Zcchc6 (also known as TUT7) and Zcchc11 (also known as TUT4) as the enzymes responsible for uridylation with further TAIL-seq experiments using morpholino-mediated knockdown. The maternal RNA clearance in zebrafish is significantly delayed during the MZT when Zcchc6 and Zcchc11 are knocked down, indicating that uridylation facilitates mRNA decay. Furthermore, the depletion of those enzymes delays the progression to gastrula in both zebrafish and *Xenopus laevis*. Thus, uridylation is indispensable for early embryogenesis.

We previously showed that human orthologs of Zcchc6 and Zcchc11 are pivotal to uridylation of messenger RNAs for their decay, and prefer short poly(A) tails. Our current data suggest that Zcchc6 and Zcchc11 contribute to selective clearance of molecules with short poly(A) tails. Indeed, maternal RNAs with shorter poly(A) tails elude the degradation in the MZT when the expression of Zcchc6 and Zcchc11 proteins are repressed.

In conclusion, Zcchc6 and Zcchc11 add uridine tails to short poly(A) tails in the vertebrate MZT, which is essential for the precise regulations of maternal factor expression in the early embryogenesis.

Z565 Testing the *in vivo* consequences of splicing and transcriptional crosstalk. *A. De La Garza*, T. Bowman. Albert Einstein College of Medicine, Bronx, NY.

Departments of Developmental and Molecular Biology and Medicine (Oncology), Gottesman Institute of Stem Cell Biology and Regenerative Medicine

Splicing and transcription are tightly intertwined processes that occur simultaneously. Disruption of the spliceosome or inhibition of splicing in cultured cells and yeast leads to transcriptional stalling, suggesting the existence of a transcriptional checkpoint that is linked to splicing. It is unclear if this occurs *in vivo* and if there are specific phenotypic consequences associated with activating a splicing checkpoint. To investigate if disruption of the spliceosome affects transcriptional elongation *in vivo*, we utilized a zebrafish loss-of-function mutant for the core spliceosomal component *sf3b1 (splicing factor, 3b subunit 1)*. In order to detect transcriptional stalling, we conducted Pol II ChIP-seq of wild type and mutant embryos, and are analyzing the results to determine if the position of RNA PolII across gene bodies is altered. To corroborate the Pol II ChIP-seq results, we will also analyze nascent RNA lengths in genes that are misexpressed in *sf3b1* mutants. Additionally, *sf3b1* mutants have defects in hematopoietic stem and progenitor cell (HSPC) formation from hemogenic endothelial cells. HSPCs require high transcriptional levels to arise from endothelium.To determine if there is transcriptional impairment in the hemogenic endothelium in the mutant, we employed flow cytometry to measure the amount of 5-ethynyluridine (EU) incorporation into RNA in *flk1:gfp* positive endothelial cells in wild-type and *sf3b1* siblings. The mutant endothelial cells had two-fold less EU incorporation than their wild-type siblings indicating that loss of *sf3b1* leads to a diminished transcriptional output. These studies will help determine if spliceosomal disruption causes transcriptional stalling *in vivo*, and whether the HSPC formation defects observed in *sf3b1* mutants are caused by transcriptional deficiencies.

Z566 Longterm Regulation of Zebrafish Behavior by Maternal Rest/NRSF is Mediated by *snap25a/b*. *Howard I. Sirotkin*[1], Cara E. Moravec[1], John Samuel[2], Wei Weng[3], Ian C. Wood[4]. 1) Stony Brook University, Stony Brook, NY; 2) Seneca College, Toronto, Canada; 3) Ingenious Targeting Labs, Ronkonkoma, NY; 4) University of Leeds, Leeds, UK.

During embryonic development, regulation of gene expression is key to creating the many subtypes of cells that an organism needs thoughout out its lifetime. Recent work has shown that maternal genetics and environmental factors have lifelong consequences on diverse processes ranging from immune function to stress responses. The RE1-silencing transcription factor (Rest) is a transcriptional repressor that interacts with chromatin-modifying complexes to repress transcription of neural specific genes during early development. In zebrafish, *rest* is maternally expressed and the chromatin modifications mediated by Rest have may exert long-term effects. We found that maternally supplied *rest* regulates expression of target genes during larval development and has lifelong impacts on behavior. Larvae deprived of maternal *rest* are hyperactive and show atypical spatial preferences. As adults, male but not female fish deprived of maternal *rest* present with atypical spatial preferences in a novel environment assay. To identify key targets of maternally supplied *rest,* we utilized transcriptome sequencing and found 158 genes that are repressed by maternal *rest* in blastula stages embryos. Expression analysis revealed that maternal *rest* is required to repress expression of several of these targets for extended periods (up to 6 dpf). Disruption of the RE1 sites in either of two of these genes, *snap25a*

and *snap25b* resulted in behaviors that recapitulate the hyperactivity phenotype caused by absence of maternal *rest*. Both the maternal *rest* mutants and *snap25a* RE1 site mutants have changes to the primary motor neuron architecture that is characteristic of overexpression of *snap25*. These results demonstrate that maternal *rest* represses *snap25a/b* to modulate larval behavior and that early Rest activity has lifelong behavioral impacts.

Z567 TFAP2A drives melanocyte gene expression in parallel with MITF. *H. E. Seberg*[1], E. Van Otterloo[1], S. K. Loftus[2], G. Bonde[1], R. Sompallae[1], J. F. Santana[1], J. R. Manak[1], W. J. Pavan[2], R. A. Cornell[1]. 1) University of Iowa, Iowa City, IA; 2) National Human Genome Research Institute, Bethesda, MD.

Disruption of the transcription factor network governing melanocyte differentiation contributes to the pathogenesis of pigmentation disorders and melanoma. While this network is well-studied, many details are unresolved. Transcription factor activator protein 2 alpha (TFAP2A) is expressed in melanoblasts and mutations in this gene cause pigmentation phenotypes in humans, mice, and zebrafish. However, the the transcriptional targets of TFAP2A, and the extent to which they are shared with MITF, a master regulator of melanocyte biology and melanoma progression, have been unclear. To determine the position of TFAP2A in the melanocyte gene regulatory network, we used microarray analysis in zebrafish and mouse immortalized melanocytes (melan-a cells) to profile genes that are downregulated in the absence of TFAP2A. We then conducted anti-TFAP2A ChIP-seq to create profiles of TFAP2A-bound loci in melan-a cells and human primary melanocytes. Genes at the intersection of the microarray and ChIP-seq profiles are likely direct targets of TFAP2A. These include *mc1r* and several melanin synthesis or melanosome structural genes, most of which are also thought to be direct targets of MITF. Comparison of our TFAP2A ChIP-seq profile with a published MITF ChIP-seq profile showed that TFAP2A peaks overlap MITF peaks at a large fraction of promoters and enhancers active in these cells. In reporter assays, deletion of TFAP2A binding sites decreased activity of a minimal TRPM1 promoter, similar to published results for deletion of MITF binding sites from this element. Furthermore, counts of embryonic melanocytes indicate a genetic interaction between *tfap2a* and *mitfa* in zebrafish. The significance of these findings is, first, they show that TFAP2A and MITF work in parallel to promote gene expression in melanocytes. Second, they show that a widely-expressed transcription factor, TFAP2A, cooperates with a more tissue-restricted transcription factor, MITF, to directly regulate expression of lineage-specific melanocyte genes. Third, they indicate that the reduction of TFAP2A expression levels observed in advanced melanoma is a cause and not an effect of melanoma progression, as such a reduction would be expected to decrease the pro-differentiation effect mediated by TFAP2A.

Z568 Tet-mediated DNA hydroxymethylation is required for retinal neurogenesis. *Pawat Seritrakul*[1,2], Jeffrey Gross[1]. 1) University of Pittsburgh, PA; 2) University of Texas at Austin, TX.

Tet dioxygenases convert 5-methylcytosine (5mC) into 5-hydroxymethylcytosine (5hmC), epigenetic marks that are thought to regulate gene expression. How 5mC and 5hmC facilitate gene expression that underlies cellular differentiation during vertebrate eye development has not been resolved. The zebrafish retina is composed of neuronal and glial cells derived from a common pool of seemingly indistinguishable retinal progenitor cells (RPCs), serving as an ideal structure in which to study the epigenetic regulation of cellular differentiation. Gene expression analyses reveal that *tet2* and *tet3* are expressed in the developing retina. To functionally test the roles of these enzymes, we generated loss-of-function mutations in these genes. Homozygous mutant embryos deficient in either *tet2* or *tet3* showed no visible phenotype. However, double mutant (*tet2*$^{-/-}$*; tet3*$^{-/-}$) embryos developed ocular defects; they are microphthalmic, lack an optic nerve, and possess reduced numbers of differentiated neurons. BrdU incorporation assays showed elevated numbers of proliferative RPCs, and in situ hybridization revealed expanded RPC marker gene expression. Immunohistological and gene expression analyses revealed that the neurogenesis phenotype is likely due to failure of retinal neurons to terminally differentiate. RNA-seq analyses of gene expression in dissected eye tissues revealed reduced expression of terminal differentiation markers and upregulation of genes not normally expressed in the eye, suggesting that RPCs may be mis-specified when tet protein function is disrupted. To independently test this model, we generated inducible transgenic tet overexpression lines to artificially drive 5mC to 5hmC conversion. Embryos expressing the transgenes show increased global levels of 5hmC and defects in RPC differentiation. At the genome-wide level, virtually nothing is known about how the 5mC/5hmC landscape changes during the RPC to neuron transition. To profile these marks at single nucleotide resolution, we performed bisulfite sequencing, hydroxymethylation profiling, and RNA-seq using pure RPCs isolated from *vsx2*:GFP embryos, which express GFP in RPCs prior to differentiation. Initial analyses revealed reduced 5mC levels and enrichment of 5hmC at regulatory regions of known RPC genes, while genes expressed in other cell types maintain high 5mC levels. This correlates with RNAseq data, where RPC-specific genes are highly expressed. Ongoing work is aimed at profiling both 5hmC and 5mC at a genome-wide level during neurogenesis, utilizing a similar strategy to isolate pure populations of differentiated neuron types. Together, our work is the first evidence that tet proteins and 5hmC are required for normal retinal development.

Z569 Genomic dissection of conserved transcriptional regulation in intestinal epithelial cells. *Colin Lickwar*[1], J. Gray Camp[2], Matthew Weiser[3], David Kingsley[2], Shehad Sheikh[3], John Rawls[1]. 1) Duke University, Durham, NC; 2) Stanford University, Stanford, CA; 3) University of North Carolina at Chapel Hill, Chapel Hill, NC.

The intestinal epithelium serves as a major site of dietary nutrient absorption and microbial interactions. These important roles for intestinal epithelial cells (IECs) are shared among all vertebrates, but underlying transcriptional regulatory mechanisms are unresolved. Here we use a comparative functional genomics approach to test the hypothesis that conserved IEC functions are achieved using conserved transcriptional regulatory mechanisms across vertebrate species. We generated genome-wide adult IEC RNA-seq and open chromatin data (FAIRE-seq or DNase-seq) from four vertebrate species: Zebrafish, Stickleback, Mouse, and Human. Despite the evolutionary distance between these species,

we observe moderate correlations between relative IEC mRNA levels of 1to1to1to1 orthologs and identify a core subset of orthologous genes comprising a vertebrate IEC signature. We also compare existing expression data of mouse and zebrafish and find additional evidence for transcriptional and functional conservation regionally along the length of the intestine. Despite conservation of expression patterns, we find that only a few open chromatin regions overlapping conserved noncoding elements (CNEs) are specifically accessible in IECs. Using transgenic reporter assays to test the regulatory potential of these regions, we identified uncharacterized CNEs neighboring orthologous *hes1/her6* loci that are sufficient to drive IEC expression in zebrafish. However, these highly conserved IEC-specific open chromatin regions are very rare, and do not explain the tissue-specific expression of most IEC genes. In contrast, we find that many non-conserved regions neighboring orthologous genes in different genomes can still drive highly similar IEC expression in zebrafish. This indicates that traditional sequence conservation metrics do not sufficiently capture cis-regulatory information that is similar between species. In accord, we identify a set of transcription factor binding motifs that are similarly enriched in open regulatory regions near IEC signature genes despite a lack of traditional sequence conservation, suggesting a conserved transcriptional regulatory network. This work establishes a genomic resource for comparing and dissecting these transcriptional regulation networks that underlie shared intestinal structure and function in vertebrate species.

Z570 Constructing gene regulatory networks underlying fate specification of multipotent progenitors in the zebrafish neural crest. *K. Petratou*[1], T. Subkhankulova[1], G. Aquino[2], H. Schwetlick[1], A. Rocco[2], R. N. Kelsh[1]. 1) University of Bath, Bath, GB; 2) University of Surrey, Guildford, GB.

The gene regulatory networks (GRNs) underlying specification of multipotent progenitors to different lineages remain poorly characterised. Using the zebrafish neural crest (NC) and its derivative pigment cell lineages as a model and employing a previously established systems biology approach, we set out to construct GRNs governing fate segregation of multipotent NC progenitors. Here, we present data used to construct the core specification GRN for the iridophore, one of the zebrafish chromatophore lineages. Mutant phenotypes identified the transcription factors Sox10, Tfec and Mitfa as well as the receptor tyrosine kinase Ltk as key players. Regulatory interactions were derived using chromogenic *in situ* hybridisation on wild-type and mutant embryos, but also by overexpressing each gene and measuring resulting changes in gene expression by qRT-PCR. Our data supported the crucial role of a *sox10*-dependent positive feedback loop between *tfec* and *ltk*, driving iridophore specification. Establishment of the core network topology was followed by mathematical modelling using a system of differential equations solved numerically in MATLAB. The biological relevance of the predicted gene expression dynamics was experimentally assessed and testable hypotheses were derived to improve the model's accuracy. Using cycles of theoretical testing and experimentation, we improved and expanded the GRN by identifying previously overlooked regulatory mechanisms and additional factors. For example, we propose that a threshold level of Ltk signalling is required to enable *tfec* upregulation. Moreover, we discovered that *sox10* expression remains upregulated throughout iridophore development, leading us to investigate candidate repressors of its melanocyte-specific downstream target, *mitfa*. Although Foxd3 is reportedly suppressing *mitfa*, we present *in situ* hybridisation, as well as *ltk*/*foxd3* co-expression data obtained by the novel and highly sensitive fluorescent labelling RNAscope technique, that surprisingly challenge the proposed ongoing role of Foxd3 in the lineage. We conclude that Foxd3 is unlikely to be the repressor of *mitfa* in this context, while the lack of iridophores observed in *foxd3* mutant embryos likely results from a role in earlier NC progenitors. Overall, our studies shed light on NC development and demonstrate the value of integrating experimental and mathematical approaches when investigating complex networks.

Z571 Emergence of Patterned Activity in the Developing Zebrafish Spinal Cord. *Y. Wan*, Z. Wei, S. Druckmann, P. Keller. HHMI Janelia Research Campus, Ashburn, VA.

Spontaneous, patterned neuronal activity has been closely linked to developmental mechanisms shaping the early nervous system and is suggested to play a key role in the fine-tuning of developing circuits. However, little is known about how patterned activity emerges *de novo* and what factors control this maturation process. Here, we use Simultaneous Multi-view (SiMView) Light-sheet Microscopy to image the emergence of patterned activity in the developing spinal cord of embryonic zebrafish. We developed imaging assays and computational tools to record embryogenesis at the cellular level and systematically track cellular dynamics and lineage relationships in the developing spinal cord. By seamlessly transitioning from developmental imaging to high-speed volumetric functional imaging, we furthermore mapped calcium activity in all post-mitotic neurons for a large fraction of the developing spinal cord at a temporal resolution of 4 Hz. These data show that spinal cord neurons undergo a rapid transition from sporadic single-neuron activity to ipsi-laterally correlated and contra-laterally anti-correlated activity between 18 and 22 hours post fertilization. We developed a computational model to reconstruct the maturation process of this spinal cord circuit from our image data at the single-neuron level and characterize dynamic changes in functional connectivity as a function of time. We found that early functional communities are first established by spatially neighboring neurons, and neighboring communities subsequently merge by synchronization to form a patterned network. The time of recruitment of neurons to the spinal cord circuit follows, on average, a gradient from the anterior to the posterior spinal cord. Finally, we identified the cell types of active neurons with genetic markers and found that different types of neurons play different roles in circuit maturation. Ventral interneurons and motor neurons appear to serve as pioneers in the emergence of local functional communities, whereas dorsal commissural neurons may play a key role in establishing and maintaining the phase-locked state between left and right hemi-segments of the spinal cord.

Z572 Automated 3D cellular-resolution phenotyping of whole zebrafish with *in situ* RNA probe libraries. *Y. Wu*[1], A. Allalou[1], M. Rezaie[1,2], P. Eimon[1], M. Yanik[1,2]. 1) Massachusetts Institute of Technology, Cambridge, MA; 2) ETH, Zurich, Switzerland.

To enable quantitative high-content phenotyping in zebrafish using large *in situ* RNA probe libraries, we have developed an optical projection

tomography platform capable of imaging complex anatomical structures and gene expression patterns rapidly and affordably in three dimensions and at high resolution. In contrast to standard 3D imaging modalities--which require expensive hardware, are often not amenable to high-throughput sample handling, and are restricted to fluorescent readouts--our system can be assembled using commercially available components and enables 3D imaging of gene expression patterns at cellular resolution in non-embedded zebrafish larvae using standard chromogenic *in situ* protocols. Image acquisition time is less than 7 seconds per embryo and the system can be paired with automated fluidics such as the Vertebrate Automated Screening Technology (VAST) system we previously developed for higher-throughput larvae handling. We have additionally developed algorithms to automate all aspects of 3D reconstruction and registration to stage-specific anatomical atlases, allowing for rapid visualization of morphology and gene expression patterns throughout early development. By applying correlation analysis to a diverse library of brain-specific probes, we are able to quantify subtle changes in gene expression patterns between experimental groups throughout the entire brains of intact animals. Applying this approach to the well-characterized *tof/fezf2* mutant, we are not only able to automatically extract virtually all previously described early developmental defects, but also to detect novel aspects of the phenotype. Quantitative phenotypic data sets such as these allow labs to more easily compare phenome-level observations and will be an invaluable tool for analyzing the numerous mutant lines being generated through the rapid adoption of genome editing tools.

Z573 A conserved role for Lef1-mediated Wnt signaling in hypothalamic neurogenesis and anxiety. *Y. Xie*[1], S. Panahi[1], H. Xue[2], C. Fung[1], E. Levine[1], H. Coon[1], R. Dorsky[1]. 1) University of Utah, Salt Lake City, UT; 2) University of Iowa, Iowa City, IA.

We have previously shown that Wnt signaling through the transcriptional effector Lef1 is required for hypothalamic neurogenesis in zebrafish. However, the specific cellular and molecular functions of Lef1 remain unknown. We find that in zebrafish, Lef1 cell autonomously promotes the differentiation of multiple periventricular neuronal subtypes from Wnt-responsive progenitors. RNAseq analysis of zebrafish *lef1* mutants supports these results, showing decreased expression of known Wnt target genes and markers for defined neuronal subtypes that regulate anxiety. Indeed, we find that zebrafish *lef1* mutants display enhanced anxiety in a novel tank diving test, and gain weight more slowly than control siblings, which is consistent with enhanced anxiety. Analysis of a conditional hypothalamic *Lef1* knockout mouse shows similar neurogenesis defects, as well as decreased expression of orthologous genes that are co-expressed with *Lef1* in the mouse hypothalamic posterior periventricular and premammillary nuclei. Conditional *Lef1* knockout mice also gain weight more slowly than controls, and we are currently testing their behavior. Finally, we have found a human *LEF1* variant that is significantly enriched in Utah suicide cases, compared to equivalent control populations. Together, these data suggest a conserved role for Lef1 in regulating the development of hypothalamic circuits that mediate anxiety. We believe that our genetic models may prove useful in clinical medicine for the diagnosis and treatment of anxiety-related mental disorders.

Z574 Injury-induced *ctgfa* directs glial bridging and spinal cord regeneration in zebrafish. *Maryssa H. Mokalled*[1], Chinmoy Patra[2], Amy L. Dickson[1], Toyokazu Endo[1], Didier Y. Stainier[2], Kenneth D. Poss[1]. 1) Duke University Medical Center, Durham, NC; 2) Max Planck Institute for Heart and Lung Research, Bad Nauheim, Germany.

Unlike mammals, adult zebrafish efficiently regenerate functional nervous system tissue after major spinal cord injury. Whereas glial scarring is a major roadblock for mammalian spinal cord repair, glial cells in zebrafish form a bridge across severed spinal cord tissue and facilitate regeneration, a process about which little is known. Here, we performed a genome-wide profiling screen for secreted factors that are induced during zebrafish spinal cord regeneration. We find that *connective tissue growth factor a* (*ctgfa*) is induced in and around the glial cells that participate in initial bridging events. Mutations in *ctgfa* permit development to adulthood but disrupt spinal cord repair, whereas transgenic *ctgfa* overexpression and local recombinant protein delivery accelerate bridging and functional regeneration. Our study reveals Ctgf as a pro-regenerative factor that is necessary and sufficient to stimulate glial bridging and natural spinal cord regeneration.

Z575 Light-dependent regulation of sleep/wake states by prokineticin 2 in zebrafish. *D. Prober*[1], S. Chen[1], S. Reichert[2], J. Rihel[2]. 1) California Institute of Technology, Pasadena, CA; 2) University College London, London, UK.

Light affects sleep/wake behaviors indirectly by providing a cue that entrains circadian rhythms but also via direct regulation of behavior through a phenomenon known as masking. While circadian entrainment by light is well characterized at the molecular level, genes that underlie masking are largely unknown. Using zebrafish, a diurnal vertebrate, we found that both overexpression and mutation of the neuropeptide prokineticin 2 (Prok2) affect sleep/wake behaviors in a light-dependent but circadian-independent manner. We also found that the Prok2 overexpression phenotype requires *prokineticin receptor 2* and that Prok2 overexpression induces expression of *galanin*, a known sleep-inducing peptide, in the hypothalamus in a light-specific manner. These results suggest a novel genetic and neuronal circuit that links light via Prok2 to a known sleep-promoting center.

Z576 A forward genetic screen identifies Huntingtin-interacting protein 14 as an *in vivo* regulator of zebrafish habituation learning. *J. C. Nelson*[1], R. Jain[2], M. Granato[1]. 1) University of Pennsylvania, Philadelphia, PA; 2) Haverford College, Haverford, PA.

Learning reflects the ability of animals to modify behavioral responses using new information obtained from the environment. Habituation is learning in its simplest form: animals cease to respond to repeated but non-threatening visual, tactile or acoustic stimuli. In humans, habituation and other sensory thresholding processes are disrupted in multiple psychiatric and neurodegenerative disorders. Despite its importance, the genetic programs and molecular mechanisms that govern the assembly and function of the neuronal circuits critical for habituation learning are not well understood. Zebrafish exhibit numerous complex behaviors relevant to the study of neuropsychiatric

disorders, including acoustic startle habituation, with kinematic and pharmacodynamic parameters identical to those observed in adult zebrafish and mammals (Wolman et al, PNAS 2011).

To identify the genetic programs that govern vertebrate habituation learning, we have conducted the first forward genetic screen for genes critical for zebrafish startle habituation. This screen has yielded fifteen mutants with deficits in habituation learning, and through whole genome sequencing (WGS) we identified the PAPPAA metalloprotease as a novel regulator of IGF-dependent habituation learning (Wolman et al, Neuron 2015). Using WGS, we have since mapped 3 additional habituation mutants, identifying presumptive null mutations in *ap2s1*, *cacna2d3* and *zdhhc17/hip14*, implicating diverse cellular processes from Clathrin-mediated endocytosis to protein palmitoylation in modulating habituation learning. HIP14, or Huntingtin-Interacting Protein 14, is a palmitoyl acyl transferase that physically interacts with the Huntington's disease-associated Huntingtin protein. We will present behavioral analyses of all mutants, as well as a characterization of neuronal and synaptic morphology in known circuit components in *hip14* mutants. Together, these genes represent an unique opportunity to probe the cell and molecular mechanisms critical for the formation and function of the circuits underlying vertebrate learning behaviors.

Z577 Larval zebrafish show individual left/right bias in movement direction during local light-search behavior. *Eric Horstick*, Yared Bayleyen, Harold Burgess. NIH, Bethesda, MD.

Motivated states allow plasticity of an animal's behavior, facilitating adaptive responses to fluctuating homeostatic states and external challenges. A nearly universal motivated drive exists for finding resources. These goals are achieved by active modulation of sensory responsiveness and locomotor patterns. Despite the importance of these goal-directed behaviors for survival, the underlying neural mechanisms are still poorly understood. Here we report the identification of a novel light-search state in zebrafish that surprisingly includes an individual preference for left or right-ward movement. Using spatial analysis we found that after loss of illumination, larvae first show movement patterns consistent with a local light-search behavior that transitions to an outward exploratory phase. Each phase of the search exhibits distinct patterns of sensory responsiveness and movement trajectories that allow efficient navigation to local or remote sources of illumination respectively. Zebrafish *otp* mutants, null for the transcription factor Orthopedia, and previously demonstrated to have a reduced visual motor response, failed to transition out of local-search. Orthopedia is required for mid-brain dopaminergic (DA) neurons, neurosecretory neurons, and opn4a expressing deep-brain photoreceptors. Using mutants we found that the *otp* phenotype was not due to DA neuron loss, and was at least partially due to opn4a deep-brain photoreceptors. Next we sought to resolve the circuitry underlying the lateralized turning behavior. During local search, individuals show a robust preference for turning either left-ward or right-ward. Repeatedly testing individuals showed that an individual's left/right turn bias persisted for at least 2 days. We have excluded genetic inheritance, sensory input, and retinal circuitry as the source of the bias. To locate circuitry establishing the bias we genetically ablated 40 different Gal4 enhancer trap labeled neuronal populations and tested for turn preference. Ablation of the xa170 enhancer trap abolished lateralized turning behavior. The xa170 expression pattern labels several populations of neurons including pineal projection neurons and hypothalamic neurons. Functional whole brain activity mapping confirmed increased pineal activity during lateralized turning implicating pineal output in the maintenance of lateralized behavior. Thus, loss of illumination initiates a behavioral state consistent with conserved search strategies observed in numerous species including *C. elegans*, *Drosphila* and mammals. This state is temporally regulated by Orthopedia specified neurons. In addition, the initial phase of the behavior exhibits a persistent left/right preference. Using this novel model we aim to dissect the circuitry of goal-mediated responses and motor asymmetry and how these impact behavioral choice.

Z578 Neuro-taxonomy: Towards a complete parts list of the zebrafish central nervous system. *H. Baier*, M. Kunst, E. Laurell. Max Planck Institute of Neurobiology, Martinsried, DE.

One major obstacle to progress in neuroscience is the lack of knowledge about the neuron classes that make up the CNS. How many discrete cell types exist, and what is the "morphospace" of each of these types? In order to tackle this problem, we propose a combined genetic and anatomical approach to neuron classification at a large scale using larval zebrafish (*Danio rerio*). Zebrafish have ideal properties for this approach since they are translucent and easily amenable to genetic modification. Their brains are relatively small (ca. 90,000 neurons at 6 days post-fertilization) but display the basic architecture that is conserved across vertebrates. The small size permits this approach to reach full brain coverage in the near future. We are using a genetic tool that stochastically labels individual neurons with membrane-targeted fluorophores. Optical access and visualization are further facilitated by prior tissue clearing with a streamlined Clarity protocol. Labeled neurons are imaged by confocal microscopy at high resolution and reconstructed for quantitative morphological analysis. Because the method is based on the Gal4/UAS system, it will be possible, in the future, to target defined neuronal populations in order to combine genetic identity with morphological analysis. A variation of this tool tags pre-synaptic sites with a second, genetically encoded fluorophore, which gives information about the direction of information flow between neighboring cells and between interconnected brain regions. Currently, we have reconstructed >1,000 neurons from a pan-neuronal expression pattern and recorded their morphologies. Future efforts in our laboratory will be directed at automating image acquisition and establishing an image-processing pipeline, which will greatly accelerate our throughput. In order to compare neurons between individual fish, we are aligning them to a high-resolution, age-matched standard brain. This reference brain will consist of several different markers giving other researchers the flexibility of using a reference stain that best suits their experimental paradigm. Furthermore, combining all these markers into one standard brain will give us further insight into the functional modules that make up the larval zebrafish brain. This new database of zebrafish neurons will initially be populated by their morphological properties, anatomical location and transmitter type, but can be expanded to include functional, developmental and gene expression data. With support from a local supercomputing center, it is planned to make the database a web-accessible resource for the community and link it to ZFIN. This will give

zebrafish neuroscientists the ability to browse the stored information, upload data from their own experiments and carry out similarity searches, analogous to BLAST or PDB.

Z579 Identifying roles for Pbx factors in heart development and congenital heart defects using zebrafish genome engineering. *L. Maves*[1,2], G. Farr[1], D. Pouv[1,2], R. Kao[1], K. Magham[1,2], M. Majesky[1,2]. 1) Seattle Children's Research Institute, Seattle, WA, USA; 2) University of Washington, Seattle, WA, USA.

Work from our group and others has implicated Pbx homeodomain transcription factors in myocardial differentiation and outflow tract development. However, the mechanisms underlying Pbx function in heart development are not understood, and it is not known whether Pbx factors causally contribute to human congenital heart defects. We have used the CRISPR-Cas9 system to engineer zebrafish strains for a variety of pbx gene alleles to determine the roles of Pbx factors in heart development. First, we have used null alleles of the pbx2 and pbx4 genes to show that zebrafish embryos lacking both pbx2 and pbx4 show severe defects in early myocardial differentiation, myocardial morphogenesis, and outflow tract formation. Second, we have engineered in-frame deletions within the pbx4 gene to demonstrate critical functions in heart development for a domain conserved in Pbx proteins. Third, we have engineered a zebrafish strain carrying a Pbx gene variant that has been associated with congenital heart defects in human patients. We are using this strain to identify causative effects of this variant on heart and outflow tract development. Our zebrafish pbx gene alleles now allow us to test whether Pbx proteins function through transcriptional activation or repression in myocardial differentiation. Our studies provide novel examples of using genome engineering for structure-function analyses of critical heart transcription factors as well as for testing human variant functions in heart development.

Z580 An essential splice site mutation in flt1 protects against early-stage atherosclerosis in zebrafish larvae. *Marcel den Hoed*[1], Manoj bandaru[1], Lisa Conrad[1], Anastasia Emmanouilidou[1], Petter Ranefall[2], Carolina Wählby[2], Anders Larsson[3], Erik Ingelsson[1]. 1) Department of Medical Sciences, Molecular Epidemiology and SciLifeLab, Uppsala University, Sweden; 2) Department of Information Technology, Division of Visual Information and Interaction and SciLifeLab, Uppsala University, Sweden; 3) Department of Medical Sciences, Biochemical structure and function, Uppsala University, Sweden.

Objective: Genome-wide association studies (GWAS) identified 56 loci that are robustly associated with the risk of coronary artery disease (CAD). Only a handful of genes in these loci are currently known to influence CAD. We previously showed that: 1) CAD-associated loci exert their effect at least in part by influencing atherosclerotic plaque formation; 2) zebrafish larvae represent a robust model system for high-throughput, image-based screens of early-stage atherosclerosis. We now aim to identify causal genes in GWAS-identified loci for CAD using zebrafish model systems.

Methods: Heterozygous carriers of nonsense (sa1516 in cxcl12b; fh336 in col4a1) or essential splice site (sa1504 in flt1) mutations were in-crossed, and offspring were fed on a normal or high amount of a normal or high cholesterol diet from 5 to 10 days post-fertilisation. Vascular lipid deposition (monodansylpentane cadaverase) and co-localisation of lipids with macrophages (*Tg:mpeg1-mCherry*) and/or neutrophils (*Tg:mpo-EGFP*) were subsequently visualised using an automated positioning system, fluorescence microscope and CCD camera, and objectively quantified using a custom-written image analysis pipeline in ilastik, CellProfiler and ImageJ. After imaging, whole-body total cholesterol and triglyceride levels were assessed using enzymatic assays, and larvae were genotyped using KASP technology. A multilevel (hierarchical) mixed model analysis was performed to examine the effect of the mutations (additive model) on atherogenic traits, while adjusting for diet and time-of-imaging, as well as for batch (random factor).

Results: In data from up to 253 larvae, sa1504 in flt1 was associated with less vascular lipid deposition (P=2E-5), less co-localisation of lipids and macrophages (P=9E-3), and lower whole body total cholesterol levels (P=2E-2). No significant effects were identified for the sa1516 and fh336 mutations (N up to 223 and 344, respectively).

Discussion: Our results represent the first mutant model demonstrating that flt1 plays a role in early-stage atherosclerosis, implying that *FLT1* is the culprit for CAD in the 13q12 locus. Based on the results of *a priori* performed bioinformatics analyses, we believe that *CXCL12* and *COL4A1* remain the most promising candidates in their respective loci. The lack of effect for these genes in our screen may reflect genetic redundancy, adaptation and/or a late onset effect.

Z581 Mutations in COL22A1 cause a loss of vascular integrity that result in intracranial aneurysms. *Quynh V. Ton*[1], Daniel Leino[1], Joseph Broderick[2], T. Foroud[2], Allison Lubert[1], J. Farlow[2], D. Woo[2], Saulius Sumanas[1]. 1) Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 2) University of Cincinnati, Cincinnati, OH.

Intracranial saccular aneurysms (IAs) are balloon-like or small berry defects in the wall of the major intracranial artery. Both environmental and genetic factors have been linked to the formation of IAs, but genetic risk factors of IAs are largely unknown. To identify additional genes responsible for IA development, whole exome sequencing of the patients from seven selected families was performed. One of the identified variants found in all five affected members of one family was a missense mutation in the highly conserved triple-helix region of the collagen *COL22A1* isoform, the function of which has not been previously known. This mutant variant was examined in zebrafish embryonic and adult models. We demonstrated that *COL22A1* is expressed in adjacent to the eyes, in the cranial tissues, in the myotendinous junctions, and in perivascular cells in the head region of the embryos. Early global overexpression of the human mutant but not wild-type *COL22A1* in the zebrafish embryos interfered with epiboly movements during gastrulation due to the retention of the mutant protein in the cytoplasmic domain that led to an induction of Endoplasmic reticulum stress response. Inducible overexpression of the human mutant protein at a later stage resulted in the increased percentage of embryos with hemorrhages compared with the wild type protein. These data further suggest that

the mutation has a deleterious dominant effect. We then used TALEN-engineered nucleases to generate a loss-of-function mutant in zebrafish *col22a1*. The homozygous null mutants were viable as adults but exhibited increased abnormal blood accumulations in the eyes and cranial regions, suggestive of hemorrhages. In addition, hemorrhages were present in the trunks of these adults caused by rupture of blood vessels. Furthermore, adult mutants are more susceptible to excessive forced overload cardiac stress than wild type siblings and have increased number of hemorrhages. We also demonstrated that the homozygous embryos show increased sensitivity to cardiovascular stress and exhibit greater frequency of intracranial hemorrhages, which can be partially rescued by the transient expression of wild type human COL22A1. The mutant embryos also exhibited increased vascular permeability as demonstrated by 10 kDa dextran injection into the circulation of 3 and 4-day post fertilization embryos. Our results argue that the function of COL22A1 is important in maintaining vascular integrity and that mutations in COL22A1 are one of genetic causes for intracranial aneurysms in humans.

Z582 Cure modeling human genetic skeletal muscle disorders. *N. Umemoto*, M. Urban, R. Harm, M. McNulty, K. Predmore, M. Serres, C. Daby, H. Sizek, C. Bullard, D. Hunter, X. Xu, K. Clark, S. Ekker. Mayo Clinic, Rochester, MN.

Background: Approved treatments are available for only ~5 percent of the thousands of known rare diseases. In particular, almost all neuromuscular disorders are considered orphan diseases caused by single gene defect. However, there are few approved drugs for the disorders. To overcome the bottleneck in drug discovery for these rare diseases, we hypothesize that the use of a new concept we call "cure modeling" can be used to augment traditional disease modeling such as gene knock-out animals.

Methods: To explore and identify the molecular mechanisms and signatures of health from these genetic skeletal muscle diseases, we have deployed our genome engineering technology to construct reversible mutant alleles, Protein Trap Gene-break Transposon (GBT) system in zebrafish. The main features of the GBT system are; i) GBT constructs are integrated in zebrafish genome using transposons and mapped using next gen sequencing; ii) >95% of the time, GBT alleles show 99% knockdown of the tagged endogenous transcripts; iii) mRFP reporter expression shows specific localization of the gene product; iv) Cre recombinase can be used to revert the mutant locus to wild-type function.

Results and Discussion: We have created 5 GBT cure models that have the mutant locus in orthologous zebrafish genes (*ano5a*, *ryr1b*, *dnajb6b*, *casq1a* and *gyg1a*) associated with human genetic disorders in skeletal muscle. To assess functional phenotypes of skeletal muscle in the GBT fish lines compared with or without exercise, we are screening the alteration of tcap expression, a molecular marker rapidly induced by skeletal muscle activity. Here, we report details about our findings from this unique functional phenotypic assay. These initial revertible mutants exhibit how cure modeling can represent an idealized therapy to treat a tested genetic disease at the level of transcripts, proteins, metabolites and other molecular components.

Z583 Fmrp interacts with Adar and regulates RNA editing, synaptic density and locomotor activity in zebrafish. *A. Shamay-Ramot*[1,2], K. Khermesh[1], H. Porath[1], M. Barak[1], Y. Pinto[1], C. Wachtel[1], A. Zilberberg[1], T. Lerer-Goldshtein[1,2], S. Efroni[1], E. Levanon[1], L. Appelbaum[1,2]. 1) The Mina & Everard Goodman Faculty of Life Sciences, Bar-Ilan University, Ramat-Gan, IL; 2) The Leslie and Susan Gonda Multidisciplinary Brain Research Center, Bar-Ilan University, Ramat-Gan, IL.

Fragile X syndrome (FXS) is the most frequent inherited form of mental retardation. The cause for this X-linked disorder is the silencing of the fragile X mental retardation 1 (*fmr1*) gene and the absence of the fragile X mental retardation protein (Fmrp). The RNA-binding protein Fmrp represses protein translation, particularly in synapses. In *Drosophila*, Fmrp interacts with the adenosine deaminase acting on RNA (Adar) enzymes. Adar enzymes convert adenosine to inosine (A-to-I) and modify the sequence of RNA transcripts. Utilizing the *fmr1* zebrafish mutant (*fmr1*-/-), we studied Fmrp-dependent neuronal circuit formation, behavior, and Adar-mediated RNA editing. By combining behavior analyses and live imaging of single axons and synapses, we showed hyperlocomotor activity, as well as increased axonal branching and synaptic density, in *fmr1*-/- larvae. We identified thousands of clustered RNA editing sites in the zebrafish transcriptome and showed that Fmrp biochemically interacts with the Adar2a protein. The expression levels of the *adar* genes and Adar2 protein increased in *fmr1*-/- zebrafish. Microfluidic-based multiplex PCR coupled with deep sequencing showed a mild increase in A-to-I RNA editing levels in evolutionarily conserved neuronal and synaptic Adar-targets in *fmr1*-/- larvae. These findings suggest that loss of Fmrp results in increased Adar-mediated RNA editing activity on target-specific RNAs, which, in turn, might alter neuronal circuit formation and behavior in FXS.

Z584 Pyruvate carboxylase functions in astrocytes to regulate habituation learning. *M. Wolman*, C. Jennings, L. Johnson. University of Wisconsin, Madison, WI.

Animals constantly update their behavior by evaluating the significance of current sensory input and then integrating this information with knowledge gained from prior experiences. To filter irrelevant input and focus attention towards high priority stimuli, all animals exploit a fundamental form of learning, called habituation. Habituation is observed by a progressive response decline to repeatedly experienced, yet insignificant stimuli and provides a behavioral measure of a neural circuit's ability to balance synaptic excitation, inhibition, and plasticity. Habituation deficits are observed in schizophrenia, autism, and addiction, and contribute strongly to the patients' overall dysfunction. Despite its conservation and clinical relevance, the genetic and cellular mechanisms that mediate habituation remain poorly understood.

To identify genes critical for habituation, we recently performed an unbiased, genome-wide screen for zebrafish mutants with reduced habituation of the acoustic startle response. This screen identified a functional gene set for habituation, including a gene previously unknown for a role in habituation: *pyruvate carboxylase a*. Pyruvate carboxylase (PC) is a mitochondrial enzyme that converts pyruvate to oxaloacetate to stimulate the TCA cycle, and hence, the synthesis of metabolic products with diverse biological functions. In the brain, PC is not thought to be active in neurons, but instead, functions in oligodendrocytes to promote myelination and in astrocytes to replenish neurons with

neurotransmitters. Although both glial cell types are known to support synaptic plasticity, it remains unclear how signaling pathways in either cell type directly regulate habituation.

Through molecular-genetic, pharmacological, and behavioral analyses, we will provide data showing that astrocytic PC activity supports glutamatergic neurotransmission to promote habituation. This work defines a novel molecular mechanism underlying habituation and reveals a novel cellular locus of plasticity for habituation: astrocytes!

Z585 Introgression in Zebrafish and related species was mediated by genome structure. *Braedan M. McCluskey*, Peter Batzel, Jason Sydes, John H. Postlethwait. University of Oregon, Eugene, OR.

Introgression is increasingly appreciated as a major contributor to species diversification. Using exome sequencing for zebrafish and ten related species, we show that introgression played a major role in the formation of several *Danio* species, including the zebrafish, *Danio rerio*. We find introgressed loci primarily in genomic regions with high recombination rate, which is strongly impacted by chromosome structure in zebrafish. Due to varying levels of introgression across the genome and a likely major chromosomal rearrangement, the closest historical relative of zebrafish varies for different genomic regions. These varied relationships across the genome give general insight into the effects of genome structure on introgression and the importance of incorporating structural genomic information into phylogenomic studies involving taxa with high levels of introgression. These results also provide specific insight into the complex speciation process in the recent history of a major model organism. Future studies investigating the phenotypic differences between zebrafish and other danios will need to account for this complex speciation process.

Z586 Regulation of actinodin1 in embryonic fins via tissue-specific cis-acting regulatory elements: a potential mechanism for the loss of these genes during the fin-to-limb transition. *R. Lalonde*, D. Moses, J. Zhang, N. Cornell, M.-A. Akimenko. University of Ottawa, Ottawa, CA.

The fin-to-limb transition is an important evolutionary step in the colonization of land and diversification of terrestrial vertebrates. Our lab has identified a gene family in zebrafish, termed *actinodin* (*and*), which codes for structural proteins in the teleost fin. These proteins are crucial for the formation of rigid fibrils known as actinotrichia. Actinotrichia support the fin fold, a structure formed from the extension of the apical ectodermal ridge (AER) during pectoral fin development. During limb development, the AER is maintained relatively longer prior to eventual regression. Interestingly, this gene family is absent from all tetrapod genomes examined to date, suggesting that it was lost during limb evolution. We propose that the disappearance of *and* genes resulted from modification in their regulation and we therefore characterized the regulatory elements of *actinodin1 (and1)*, one of two longer *and* paralogues (*actinodin1/2)* in zebrafish. Within a 2kb fragment immediately upstream, we have identified tissue-specific *cis*-acting regulatory elements responsible for *and1* expression in the developing zebrafish median and pectoral fin folds. Using transgenic reporter lines, we have identified and isolated the regulatory elements responsible for *and1* activation in the ectodermal and mesenchymal cell populations, respectively. To test their functionality in tetrapods, a transgenic LacZ reporter mouse line was made. In contrast to the zebrafish transgenic line, reporter expression is restricted to the ectoderm of the fore- and hindlimb buds, localizing within the autopodal domain. One possibility suggests that while the regulatory network for *and1* ectodermal activation remains intact in mice, the mechanisms for mesenchymal activation have been lost or altered during tetrapod evolution. Putative transcription factor binding sites were identified via TRANSFAC and tested for enhancer activity using site-directed mutagenesis. Removal of tcf and 5' hoxA/D binding sites lead to the loss of ectodermal and mesenchymal enhancer activation, respectively. Dissecting the regulatory mechanisms of this gene family is crucial for uncovering the mechanisms of *and* loss during tetrapod evolution. Finally, *and1 cis*-acting regulatory elements enable us to perform tissue-specific lineage tracing and ablation of *and1*-expressing cells. We are currently performing lineage tracing experiments on both ectodermal and mesenchymal cell populations using the Cre-LoxP system, in addition to observing the effects of fin fold mesenchyme ablation on fin development using the Nitroreductase/Metronidazole system. This work is supported by a NSERC grant to M.-A.A.

Z587 The MITF family member *tfec* functions in zebrafish neural crest pigment cell fate diversification. *J. Lister*, S. Spencer. Virginia Commonwealth University, Richmond, VA.

In organisms such as fish and reptiles where the neural crest produces more than one type of pigment cell, the existence of a lineage-restricted precursor of all pigment cell types has been speculated upon but not conclusively demonstrated. In zebrafish, null mutations in the *microphthalmia-associated transcription factor* (*MITF*) ortholog *mitfa* lack all neural crest-derived melanocytes but retain the other two neural crest pigment cell types, xanthophores and iridophores. In fact, *mitfa* mutants display an increased number of iridophores compared to wild-type, suggestive of a possible cell fate switch, and cell lineage experiments indicate the existence of a bipotent iridophore/melanocyte precursor. We have begun to examine another member of the zebrafish MITF family, *tfec*, which is expressed in premigratory and migrating neural crest cells and later in differentiating iridophores. Knockdown of *tfec* with antisense morpholino oligonucleotides, or by a CRISPR/Cas9 approach indicates that *tfec* is necessary for the development of iridophores. Intriguingly, knockdown of *tfec* in *mitfa* mutant embryos additionally eliminates the third pigment cell type, xanthophores. These data indicate that all three pigment cell lineages in zebrafish are dependent upon one or a combination of MITF family proteins, and suggest that perhaps the choice between these cell fates may depend in part on their relative levels. Moreover, they provide genetic evidence for a distinct pan-pigment precursor in the hierarchy of zebrafish neural crest cell fate diversification.

Z588 Evolutionary Conservation of Tcf12 and Twist1 Function in Coronal Suture Development. *C. Teng*, G. Crump, R. Maxson. University of Southern California, Los Angeles, CA.

In a normal developing child, skull bones are connected by fibrous sutures that allow pressure to be released as the brain grows and expands. Craniosynostosis is the premature fusion of these sutures in newborns and infants. In Saethre-Chotzen syndrome, a disorder characterized by synostosis of the coronal suture and other facial irregularities, heterozygous mutations in the basic helix-loop-helix (bHLH) transcription factors *TWIST1* or *TCF12* account for the majority of diagnoses. We hypothesize that Tcf12 functions as a suture-specific heterodimerization partner of Twist1 that promotes its ability to maintain osteoblast progenitors in an undifferentiated state. In support of such an interaction, loss of one allele of *Tcf12* enhances coronal synostosis in *Twist1+/-* mice. In order to understand how early changes in osteoblast differentiation may account for suture defects in individual animals, we have developed a zebrafish model of Saethre-Chotzen syndrome by generating null alleles for *tcf12* and the two zebrafish Twist1 homologs (*twist1a* and *twist1b*). Remarkably, one particular combination of alleles, *tcf12-/-*; *twist1b-/-*, survives to adulthood and displays a near complete and specific loss of the coronal suture. Whereas *twist1a*; *twist1b* double mutants have much earlier defects in specification of the neural crest-derived ectomesenchyme that generates the head skeleton, further loss of *tcf12* partially restores early craniofacial development and allows survival to adulthood. These findings suggest that Twist1 may have different binding partners during ectomesenchyme and suture development, with Tcf12 acting as a Twist1 binding partner during later suture development. While mouse coronal sutures lie at a boundary between neural crest-derived frontal bones and mesoderm-derived parietal bones, zebrafish coronal sutures lie between the mesoderm-derived portions of the frontal and parietal bones. Our data thus provide strong evidence for deep evolutionary homology of the coronal suture between fish and mammals, as the role of Tcf12/Twist1 interactions is preserved regardless of tissue origin. We are presently conducting live imaging of osteoblast differentiation over time in our zebrafish model to better understand how early defects might result in later craniosynostosis.

Z589 Fish synovial joints as new models for joint development and disease. *Joanna Smeeton*[1], Amjad Askary[1], Sandeep Paul[1], Simone Schindler[1], Ingo Braasch[2,3], Nicholas A. Ellis[4], John Postlethwait[2], Craig T. Miller[4], Gage Crump[1]. 1) University of Southern California, Los Angeles, CA; 2) University of Oregon, Eugene, OR; 3) Michigan State University, East Lansing, MI; 4) University of California, Berkeley, CA.

Synovial joints are the most common and flexible type of joint in mammals. These freely moveable joints are characterized by the presence of a synovial cavity, articular cartilage and joint capsule. A widely held view is that synovial joints first evolved in tetrapods, with fish lacking this type of joints. Surprisingly however, we found that joints in the jaw and pectoral fin of zebrafish, stickleback and spotted gar share the characteristics of mammalian synovial joints. Histological analysis and live imaging of fluorescent transgenic zebrafish from 3 days post fertilization to 12 months of age demonstrated that the zebrafish jaw joint has a synovial cavity and is wrapped in a thin joint capsule. Cartilage cells that have flattened morphology just like mammalian articular chondrocytes cover the surface of juxtaposed skeletal elements at the zebrafish jaw and fin joints. In situ hybridization analysis of genes expressed in mammalian synovial joints revealed that, similar to mammals, the zebrafish synovial joint articular cells do not express collagen type II or X, aggrecan or matrilin1, and instead express a joint lubricating proteoglycan, lubricin, encoded by the gene *prg4b*. Lubricin is secreted from the articular cells of the joint to lubricate the joint surface and its expression is one of the hallmarks of a synovial joint. To determine whether the jaw joint *prg4b* expression pattern is a conserved feature throughout ray-finned fish species, we investigated *prg4* expression in a distantly related teleost fish, the threespine stickleback (*Gasterosteus aculeatus*), and a basal ray-finned fish, the spotted gar (*Lepisosteus oculatus*). Similar to zebrafish, *prg4* homolog expression is restricted to the jaw joint articular surface in juvenile stickleback and spotted gar. Finally, genetic deletion of zebrafish *prg4b* demonstrated a conserved requirement for *prg4b* gene function in the age-related maintenance of joint cartilage. Our data represent the first molecular and functional evidence that ray-finned fish have lubricated synovial joints, supporting a model that lubricated synovial joints evolved at least in the last common ancestor of all bony vertebrates. Moreover, our results establish the zebrafish as a novel model organism to investigate synovial joint development and repair, and opens up the powerful genetic tools of the zebrafish to the field of arthritis research.

Z590 Cavefish evolution as a natural model for metabolic diseases. *N. Rohner*[1], A. C. Aspiras[2], C. J. Tabin[2]. 1) Stowers Institute for Medical Research, Kansas City, MO; 2) Harvard Medical School, Boston, MA.

Understanding the genetic basis of adaptation has broad implications not only for a basic understanding of evolution, but also for human pathologies given that many human diseases are a consequence of mis-adaptation to modern societies. The emerging cavefish model system *Astyanax mexicanus* has become an important fish species to address adaptation to extreme environments due to its unique ecology and the availability of genetic tools (e.g. QTL mapping) and genomic resources. Despite 180 million years divergence to zebrafish, cavefish is currently the closest related sequenced fish species on Ensembl.

Cave environments are typically dark and as a consequence nutrient deprived. We have previously shown that cavefish acquired impressive adaptations such as hyperphagia (increased appetite), starvation resistance and altered feeding behaviors to cope with these harsh conditions. Here, we have focused on the fatty livers and symptoms reminiscent of diabetes these fish develop. Interestingly, we detected only very low insulin levels in cavefish (compared to surface or zebrafish) partially due to lower numbers of beta-insulin producing cells in the pancreas. In addition, cavefish display strong insulin resistance when administered with ectopic insulin. Despite the consequential elevated and highly fluctuating blood glucose levels, cavefish live long and healthy lives, probing the question whether they have acquired mechanisms allowing them to cope with extreme nutritional levels.

Taking advantage of the newly available genome of *Astyanax mexicanus* and tissue specific RNA-Seq data, we identified mutations in the insulin receptor of cavefish most likely responsible for the observed insulin resistant phenotype. Importantly, the same mutations were found

in cases of Type-II diabetic patients in human populations. Our findings in independently derived cavefish populations suggest that cavefish are inherently insulin resistant, potentially as an additional strategy to acquire better starvation resistance. We are currently using genome editing to functionally test these and other candidate mutations in zebrafish and cavefish itself to study in detail the molecular mechanisms underlying the adaptation of cavefish to the extreme and nutrient poor environments, thereby providing potential new insights into human health.

Z591 *in toto* imaging of osteoblast cell cycle dynamics in regenerating zebrafish scales. *B. Cox*[1], V. Tornini[1], A. Puliafito[2], S. Di Talia[1], K. Poss[1]. 1) Duke University, Durham, NC; 2) Candiolo Cancer Institute - FPO, IRCCS, Candiolo, Torino, Italy.

The adult zebrafish can regenerate many tissues, but not all are amenable to live imaging due to their size, location, or time required to regenerate. Zebrafish scales, like fins, contain osteoblasts and epidermis, but they regenerate much more quickly after being plucked or lost during the natural course of the fish's life, recapitulating their gross structure within three to four days of loss of the original tissue. Thus, they would make ideal models for live imaging of regeneration. We have developed a method for long-term (up to twenty-four hours) live imaging of adult fish using low concentrations of anesthetic, giving us previously unprecedented access to spatiotemporal information about individual and collective cell behavior during regeneration. Through live imaging of transgenic fish expressing the FUCCI cell cycle reporter in osteoblasts (*osx*:Venus-hGeminin/*osx*:mCherry-zCdt1), we have identified a transition during regeneration from early uniform proliferation to later growth, which is spatially restricted to the borders of regenerating scales. We have developed computational methods to segment and track hundreds to thousands of osteoblasts, analyze their cell cycle and division patterns over long periods, and infer how individual cell cycle changes underlie tissue-wide growth patterns.

Z592 Plasticity & Robustness in Gastrulation: Siamese Zebrafish. *A. Ortiz*[1], S. de Man[1,2], N. Peyrières[1]. 1) BioEmergences (USR3695), CNRS, 91190 Gif-sur-Yvette, France; 2) University of Amsterdam, 1012 WX Amsterdam, Netherlands.

Embryogenesis is remarkably dynamic & precisely regulated, and the underlying morphogenetic processes are still largely unknown. We aim at understanding the plasticity & robustness of morphogenetic processes in deuterostome early embryogenesis using as a model Siamese zebrafish. Specifically, we expect insights from the quantitative analysis of the: 1) respective contributions of ingression & involution to the formation of the endo-mesodermal layer in endogenous & induced axes; 2) convergence-extension movements in Siamese compared to normal embryos; 3) dynamics of the underlying gene regulatory network. The injection of mRNA encoding a constitutive form of a Nodal pathway receptor (acvr1ba*) into a single blastomere at the 16-cell stage was used to induce a secondary axis. The co-injection of mRNA encoding H2B-mCherry was used to trace the induced axis. Also, we utilized the gsc:egfp transgenic fish line with staining under the control of the goosecoid transcription factor regulatory sequences to reveal the embryonic shields & their derivatives: notochord, prechordal plate & pharyngeal endoderm. Embryos were sorted at shield stage according to the position of the induced shield relative to the endogenous one. According to previous studies, we expected random positioning of the induced shield and an even distribution of embryos across 7 categories, position 0 being at the level of the endogenous shield and 6 being opposite to it. With current categorization of up to 600 embryos, we confirmed this hypothesis. Embryos in opposite positions, class 6, were rare suggesting the requirement for the precise balance of opposing forces, and displayed the most complete duplication of embryonic structures compared to other configurations leading to more or less extensive regulation. Answering the questions above and assessing the balance of biomechanical forces was achieved using cell tracking obtained by the automated analysis of in toto 3D+time imaging. Our best time-lapse data was obtained by 2-Photon microscopy imaging with a horizontal microscope (LaVisionBiotech). We present our most recent results in terms of cell behaviors for class 6 specimens. Our strategy toward the integration of cellular & genetic dynamics relied on the expression of transgenic reporters. Expression of the gsc transgenic reporter in the embryonic shield derivatives revealed unexpected variability with mosaic staining of notochord cells not observed in the endogenous axis. Systematically exploring transgenic reporter expression along the cell lineage is expected to reveal molecular & cellular integrated regulation mechanisms at stake in the robustness of gastrulation morphogenetic processes.

Z593 Spatiotemporal regulation of metalloprotease activity in DV patterning. *Francesca Tuazon*, Mary Mullins. University of Pennsylvania, Philadelphia, PA.

Bone Morphogenetic Proteins (BMPs) act as a morphogen to pattern dorsoventral (DV) axial tissues in invertebrates and vertebrates. The shape of the BMP gradient spatially across the DV axis is critical: precise amounts of BMP signaling at discreet DV positions specify distinct cell fates. DV patterning occurs from late blastula through gastrula stages, so the BMP gradient is also maintained temporally during gastrulation. Gastrulation and dorsal convergence generate the embryonic germ layers and body axis by rapidly reorganizing a large number of cells, challenging the mechanisms that shape the BMP gradient in space and time. To determine the shape of the BMP gradient, we developed a quantitative immunofluorescence assay of nuclear phosphorylated Smad1/5, the direct intracellular readout of BMP signaling. Using this assay, we discovered that the shape of the BMP gradient significantly changes during gastrulation: the BMP gradient steepens both dramatically and rapidly between mid- and late gastrulation stages.

Extracellular modulators of BMP ligand availability shape the BMP gradient. An essential extracellular modulator is Chordin, a BMP antagonist that binds BMP to inhibit signaling. Chordin is central to generating the initial BMP signaling gradient and continually regulates the BMP gradient during gastrulation. Chordin itself is regulated by two key classes of proteins: (i) the highly homologous metalloproteases Tolloid and Bmp1a, which cleave and inactivate Chordin, and (ii) the metalloprotease inhibitor Sizzled.

We discovered that *tolloid (tld)* and *sizzled (szl)* mutants display distinct alterations in the shape of the BMP gradient at the end of gastrulation, suggesting region-specific roles for Tld and Szl. Our data indicate that Tld maintains the steepness of the late BMP signaling

gradient, while Szl restricts BMP signaling in lateral regions. These results support a novel requirement for metalloprotease regulation during late gastrulation to steepen the BMP gradient and correctly pattern posterior tissues of the zebrafish embryo. Unlike *tld, bmp1a* is maternally deposited. We found that while MZ-*bmp1a* mutants have no DV patterning defects, MZ-*bmp1a* embryos depleted of Tld are severely dorsalized. The severity of dorsalization indicates that Tld and Bmp1a are redundant and essential to establish the BMP gradient at late blastula stages. These data support fundamental, stage-specific roles for Bmp1a/Tld to differentially shape the BMP gradient, putting forth spatiotemporal metalloprotease regulation as a central mechanism for the spatiotemporal regulation of BMP signaling.

Z594 Automated approaches to sample handling and high-throughput behavioral screening of zebrafish. *Ravindra Peravali*[1], Anna Popova[1], Daniel Marcato[1], Eduard Gursky[1], Johannes Stegmaier[2], Ruediger Alshut[4], Helmut Breitwieser[2], Robert Geisler[1], Christian Pylatiuk[2], Jos van Wezel[3], Pavel Levkin[1], Ralf Mikut[2], Uwe Straehle[1]. 1) Institute of Toxicology and Genetics, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany; 2) Institute for Applied Computer Science, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany; 3) Steinbuch Centre for Computing, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany; 4) MCC - Measure , Check & Control GmbH & Co. KG, Karlsruhe, Germany.

The zebrafish (*Danio rerio*) has emerged as a robust model organism owing to its transparency, fecundity and genetic capabilities including transgenesis and gene knock-out. In recent years, zebrafish behavioral phenotyping has been increasingly used for studying toxicological and teratogenic effects, neurological disorders and certain diseases. However, to fully exploit the advantages of the zebrafish model novel sample handling, imaging and data analysis and storage platforms are required. The Screening Facility linked to the European Zebrafish Resource Center (EZRC) has developed high-throughput behavioral screening platforms to systematically characterize zebrafish embryonic behavior. The "zebrafish sorting robot" automatically pipettes single or multiple zebrafish eggs or embryos into standard microtiter plates. This robot can operate in complete darkness and thereby facilitates experiments that demand the absence of ambient light. The "Droplet-Microarray Sandwiching Chip" is an array of superhydrophilic spots separated by superhydrophobic borders. By rolling a suspension of zebrafish embryos on the surface of the chip using a pipette we are able to spread zebrafish embryos in one-embryo-per-droplet manner without need for pipetting. This device has been successfully used to screen compound libraries and performs comparably to standard microtiter plates. Moroever, we developed a high-throughput Photomotor Response (PMR) imaging system that measures the response of zebrafish embryos at 30 – 40 hours post fertilization to flashes of bright light. This PMR platform can be completely remotely controlled thereby ensuring no human interference and extraneous sound and vibrations. Another behavioral platform quantifies the startle response using an automated acoustic vibration system combined with a very high frame rate high-resolution camera. Finally, a robotic imaging platform was developed that can assess long term locomotion and feeding behavior in an unsupervised way. In addition to the development of the imaging systems, specialized real-time and quantitative image analysis and processing pipelines have been established. These high-performance computing pipelines extract locomotor kinematics and behavioral dynamics. Furthermore, since behavioral experiments are data intensive (often leading to 7 – 10 tera bytes of data per experiment per day), a dedicated large scale data facility that has more than several peta bytes of storage and archival capacity has been established.

Z595 Quantitative *in vivo* optical tomography of cancer progression and vasculature development in adult zebrafish. *N. Lockwood*[1], S. Kumar[2], M. C. Ramel[1,2], T. Correia[1], M. Ellis[3], Y. Alexandrov[2], N. Andrews[2], R. Patel[1], L. Bugeon[2], M. J. Dallman[2], S. Brandner[3], S. Arridge[1], M. Katan[1], J. McGinty[2], P. M. W. French[2], P. Frankel[1]. 1) University College London, London, GB; 2) Imperial College London, London, GB; 3) UCL Institute of Neurology, London, GB.

We describe a novel approach to study tumour progression and vasculature development *in vivo* via global 3-D fluorescence imaging of live adult zebrafish utilising angularly multiplexed optical projection tomography with compressive sensing (CS-OPT). This method bridges a "mesocopic" imaging gap between established high resolution 3-D fluorescence microscopy techniques with whole body planar imaging and diffuse tomography.

Our new approach has been developed for imaging at multiple excitation wavelengths of non-pigmented adult zebrafish fish up to 3 cm in length. Using unfocussed illumination with two multiplexed imaging channels and iterative reconstruction of sparsely sampled OPT data, our approach requires only ~100 seconds per spectral channel for image acquisition. Using CS-OPT we imaged an inducible genetic model of liver cancer in adult transparent and fluorescent vasculature expressing zebrafish (TraNac *Tg (KDR:mCherry:Fabp10-rtTA:TRE-eGFPKRAS^{V12})*). In this disease model, addition of a chemical inducer (doxycycline) drives expression of eGFP tagged oncogenic KRAS^{V12} in the liver of immune competent animals. We show that our novel OPT methodology enables non-invasive quantitative imaging of the development of tumour and vasculature throughout the progression of the disease and validate our results against established methods of pathology including immunohistochemistry. We have validated this new imaging approach against established methods of pathology including immunohistochemistry and further demonstrated the potential of CS-OPT through a longitudinal study of vascular development in the same zebrafish from early embryo to adulthood.

To increase the metastatic potential of our cancer model we are employing novel approaches using gene editing techniques including TALENs and CRISPRs in an attempt to produce inducible knockouts in adult zebrafish, which are currently unavailable.

We believe this imaging modality with its associated analysis and data management tools constitute a new platform for *in vivo* cancer studies and drug discovery in zebrafish disease models.

Z596 Pancellular, whole-organism tissue microCT as a basis for organismal phenomics. *K. C. Cheng*[1], Y. Ding[1], A. Y. Lin[1], X. Xin[1], S. Y. Wang[2], P. La Riviere[3]. 1) Penn State College of Medicine, Hershey, PA; 2) Motorola Corp, Chicago, IL; 3) University of Chicago, Chicago, IL.

For multicellular model systems, comprehensive morphological phenotyping ideally includes assessments of every cell type in every organ system. We report the ability to use synchrotron-microCT to create 3D images of whole, fixed and metal-stained zebrafish at cellular resolutions such that virtually every cell type can be visualized and phenotyped. Sample diameters may be as large as about 1.5 mm for 0.743 micron voxel resolution and about 2.9 mm for 1.43 micron resolution. Full volumes of 3 or 4 day old zebrafish larvae at the higher resolution or 1 cm long juvenile fish at the lower resolution yield files of about 100 GB. Computer-based visualizations can be optimized for visualization of different cellular structures such as nerve tracts, blood vessels, bone, and melanocytes. This pancellular form of microCT allows volumetric measurements, the creation of slab thicknesses of any multiple of the voxel resolution, and any angle of cut. Analysis of a pola2 mutant in zebrafish shows that we are able to detect abnormalities at the cellular level including atypical nuclei, nuclear fragments, and abnormal mitoses. Since large scale projects will require far greater throughput than is currently possible, we are pursuing optimizations and standardization for sample generation and handling, instrumentation, optics, reconstruction, and visualization, under the auspices of a Synchrotron MicroCT Imaging Resource for Biology. We are recruiting partners as we plan for broad usage of this tool for samples of mm length scale, including whole worms, and flies, and parts of larger models including Arabidopsis and mammals. Automated image processing tools for phenotypic analysis are being developed in parallel with rapid imaging capabilities. Through the creation of these imaging capabilities for the research community, we hope to facilitate a far more rapid and comprehensive understanding of organismal diversity, gene function, organismal toxicity, and disease than is currently possible.

Z597 Automated Segmentation and Morphological Characterization of Neuronal Cell Nuclei in Synchrotron MicroCT Images of Whole Zebrafish. *Y. Ding*, A. Lin, K. Cheng. Penn State College of Medicine, Hershey, PA.

Our group is developing the use of synchrotron micro-computed tomography (microCT) to examine whole zebrafish in three-dimensions. The image volumes acquired from synchrotron microCT have sub-micron isotropic resolution, enabling visualization of individual cells in the context of the whole organism. Our lab is currently engaged in the design and construction of higher-throughput instrumentation for microCT imaging, allowing many zebrafish to be imaged and characterized for genetic or chemical screens. In preparation for the analysis of the resultant data, we are engaged in the parallel pursuit of analytical tools for phenotyping imaged zebrafish at the tissue and cellular levels. Due to intrinsically digital nature of the images, automated image analysis tools can be applied to enable quantitative phenotyping of the whole zebrafish. Here, we show an automated segmentation method to detect and segment neuronal cell nuclei in both wild-type and mutant zebrafish. The mutant zebrafish, *huli hutu (hht)*, causes cytological and nuclear atypia in multiple organs. First, wild-type and mutant 3-, 4-, and 5-day post-fertilization zebrafish were fixed, stained, and embedded in resin before being imaged at Beamline 2-BM at Advanced Photon Source in Argonne National Laboratory (Lemont, IL). From the synchrotron microCT images, 100 neuronal cell nuclei were manually segmented and averaged to create a template for typical neuronal cell nuclei. Next, areas in the zebrafish volumes that are most similar to the average neuronal cell nuclei are extracted for further analysis. Multiple templates can be used to detect neuronal cell nuclei of different sizes. Once the cell nuclei are extracted, morphological characteristics (i.e size, shape) of the cell nuclei are compared between wild-type and *hht* zebrafish. The zebrafish volumes can also be registered to existing digital zebrafish brain atlases, enabling the segmentation of the zebrafish brain into different regions. The morphological features of the cell nuclei are then compared among the different brain regions, in both wild-type and *hht* zebrafish. Overall, the results show that there are fewer neuronal cell nuclei in the mutant zebrafish. The size distribution of the cell nuclei is also different between *hht* and wild-type zebrafish, with *hht* having an increased fraction of smaller objects of nuclear density, consistent with nuclear fragmentation/apoptosis. The work presented here shows that automated tools can be used for quantitative phenotyping based on synchrotron microCT images of whole zebrafish. Ongoing research is focusing on extending this method to segment other cell types, organ systems, and tissue phenotypes.

Z598 Diverse structures and functions of pharyngeal teeth in teleost (zebrafish, medaka, carp, snowflake moray) live-imaged by synchrotron X-ray cinematography. *K. Hatta*[1], S. Shiomoto[1], S. Nomura[1], T. Inoue[1], K. Kuwabara[1], K. Uesugi[2], A. Suzu[3], K. Fujita[1], T. Harada[1], T. Ikenaga[1,3]. 1) University of Hyogo, Akou-gun, Hyogo, JP; 2) JASRI, Sayou-gun, Hyogo, JP; 3) Kagoshima University, Kagoshima, JP.

Many teleost have teeth not only on the jaws but also in the pharynx. The latter is called pharyngeal teeth, and their size, shape, and distribution are highly diversified. For example, zebrafish has no oral teeth, but has 10-20 'cone-shaped' pharyngeal teeth only on the 5th pharyngeal bones. Medaka, on the other hand, have oral teeth and 'more than 1000 small, cone-shaped' pharyngeal teeth distributed on the 2nd / 4th dorsal and the 5th ventral pharyngeal bones. Although the molecular, cellular and genetic mechanisms of their development have been studied, how the pharyngeal teeth are used for feeding in these species had been unknown since they are hidden deeply inside. Previously, by X-ray micro-computed tomography and cinematography at SPring-8 (BL20B2), we have succeeded in visualizing not only their 3D structures but also the movement during feeding, for the first time (2007B1795, 2008A1754, 2009B1911). Here we obtained additional movies at higher resolution and analyzed their motions during feeding (2012A1113, 2013A1161, 2014B1377). We also succeeded in live-imaging the movement of pharyngeal teeth in several other teleost species including carp, which is a close relative of zebrafish but has ‘molar-shaped’ teeth, eating snails, and snowflake moray, which has a distinct ‘tongs-like second jaws’, eating a slice of squid or a living zebrafish (2014A1475, 2015B1531). We are hoping that these data provide basic information to elucidate how such diverse 3D morphologies and functions of pharyngeal teeth arised during teleost evolution.

Z599 Calcium signalling mediated by *tmem33* is essential for endothelial tip cell function during angiogenesis in zebrafish. *A. M. Savage*[1,2], H. R. Kim[2], E. Markham[2], E. Honore[3], F. J. M. van Eeden[2], T. J. A. Chico[1,2], R. N. Wilkinson[1,2]. 1) Department of Infection, Immunity and Cardiovascular Disease, University of Sheffield, Western bank, Sheffield, UK; 2) Bateson Centre, Firth Court, University of Sheffield, Western bank, Sheffield, UK; 3) Institut de Pharmacologie Moleculaire et Cellulaire, Nice, France.

During angiogenesis, endothelial cells (ECs) sprout from pre-existing vessels driven by the response of endothelial tip cells to a gradient of VEGF. Stalk cells, which are determined through lateral inhibition via Notch signalling, are unable to respond to VEGF signals and migrate under the guidance of the tip cell. Calcium signalling is activated in ECs following stimulation by VEGF, which is dependent upon function of the calcium release-activated calcium (CRAC) channel. We have generated a transgenic zebrafish reporter of calcium signalling in ECs (*fli1-gff; uas-gcamp7a)*. Using light sheet microscopy, we are able to visualise real-time EC calcium signalling *in vivo*. Inhibition of TRPV4 reduces calcium oscillations and delays segmental artery (SeA) migration, indicating TRPV4 may play a role in SeA development.

TMEM33 is a 3-transmembrane domain protein and putative component of the calcium signalling pathway which interacts with known calcium channels, PKD1 and PKD2 in mice. Zebrafish *tmem33* morphants exhibit angiogenic branching defects. Furthermore, *tmem33* knockdown attenuates EC calcium signalling, decreases EC filopodial dynamics and delays segmental artery migration, suggesting morphant ECs display a reduced response to VEGF signalling. Overexpression of VEGF mRNA does not rescue the *tmem33* morphant phenotype. Inhibition of VEGF in zebrafish ECs also attenuates calcium signalling. Collectively, these data indicate *tmem33* lies downstream of VEGF. Conversely, inhibition of Notch signalling in zebrafish embryos increases the frequency of calcium oscillations in ECs during angiogenesis. Zebrafish *mindbomb* mutants, which are Notch signalling deficient, exhibit increased *tmem33* expression, while *tmem33* morphants display attenuated Notch signalling, indicating Notch may be involved in negative feedback regulation of *tmem33*.

Interestingly, *tmem33* mutants display nonsense-mediated decay of *tmem33* transcripts, yet exhibit normal angiogenesis. *tmem33* mutants also exhibit resistance to *tmem33* morpholinos, suggesting genetic compensation exists in the *tmem33* mutant.

Z600 Lgr6 Is A Wnt Target That Promotes Support Cell Proliferation In The Regenerating Lateral Line Neuromast. *Jonathan Kniss*, Sofia Robb, Tatjana Piotrowski. Stowers Institute for Medical Research, Kansas City, MO.

Mechanosensory hair cells in the zebrafish, and other nonmammalian vertebrates, are capable of regeneration after damage, whereas mammals are largely unable to regenerate hair cells. However, across vertebrates many of the same pathways are required for hair cell formation: Wnt/β-catenin signaling promotes proliferation of sensory progenitor cells and Fgf and Notch signaling activate and restrict expression of the prosensory transcription factor atoh1. atoh1 is also required for differentiation and hair cell maturation. The zebrafish lateral line is composed of mechanosensory organs (neuromasts) that are functionally analogous to the mechanoreceptors of the mammalian inner ear. Mature hairs cells within each neuromast are constantly replenished during homeostasis, and hair cell regeneration occurs rapidly after damage. We are using the zebrafish lateral line to dissect the roles of Wnt, Notch and Fgf signaling in support cell proliferation and hair cell differentiation during homeostasis and regeneration. Our previous work showed that in mature neuromasts, Notch and Wnt signaling balance support cell proliferation and hair cell differentiation. However, the genes regulated by these pathways during regeneration are still unknown. In mammalian tissues, the leucine-rich repeat-containing G-protein-coupled receptor (LGR) family members Lgr4/5/6 are stem cell markers in the intestinal epithelium, the hair follicle niche and the cochlea. In zebrafish, we have been unable to identify *lgr5* by sequence similarity or phylogenetic analysis, but *lgr4* and *lgr6* are expressed during lateral line development. However, only *lgr6* is expressed in support cells that surround lateral line hair cells in mature neuromasts. Our functional analyses using heatshock inducible and *lgr6* mutant lines demonstrate that *lgr6* is a Wnt target in mature neuromasts. Wnt/β-catenin promotes support cell proliferation after hair cell damage and our results suggest that Wnt/β-catenin regulates proliferation via Lgr6 during hair cell regeneration. Lgr6 is also regulated by Fgf and Notch signaling and our studies reveal a regulatory network between the Wnt, Fgf, Notch and Lgr6 pathways that balance proliferation and differentiation during homeostasis and regeneration. These findings are important for designing therapies to induce hair cell regeneration in mammals.

Z601 *In vivo* ranking of RASopathy MEK1 variants using functional assays in zebrafish and *Drosophila*. *Granton A. Jindal*[1,2,3], Yogesh Goyal[1,2,3], Kei Yamaya[3,4], Alan S. Futran[2,3], Iason Kountouridis[3], Courtney A. Balgobin[4], Trudi Schüpbach[4], Rebecca D. Burdine[4], Stanislav Y. Shvartsman[2,3,4]. 1) These authors contributed equally to this work; 2) Department of Chemical and Biological Engineering, Princeton University, Princeton, NJ; 3) The Lewis-Sigler Institute for Integrative Genomics, Princeton University, Princeton, NJ; 4) Department of Molecular Biology, Princeton University, Princeton, NJ.

Germline mutations in components of the Ras/MAPK signaling pathway result in developmental disorders called RASopathies, affecting ~1/1000 human births. Advances in genome sequencing are making it possible to identify disease-related mutations, but currently there is no framework for patient-specific predictions of disease progression based on the individual mutations. Here, we focus on all 14 MEK1 mutations found in RASopathies as well as 2 MEK1 mutations found only in cancer. We find that these can be robustly ranked according to their effect on oval shape of the zebrafish embryo at 11 hours post fertilization (hpf) and lethality fraction at 48 hpf using a quantitative, but also quick and inexpensive approach of MEK1 variant overexpression by microinjection of mRNA at the 1-cell stage. We found that mutations identified in cancer were stronger than those identified in both RASopathies and cancer, which, in turn, were generally stronger than those identified only in RASopathies. We also find that this rank extends to heart size at 20 hpf in zebrafish, another Ras/ERK-dependent developmental process. Moreover, this rank is conserved in other fly-specific assays including ectopic wing vein formation and lethality fraction. Finally, we show that this rank is predictive of MEK inhibitor dosages needed to reverse the oval shape defect, although there is a balance between correcting a

particular defect fully and altering other Ras/ERK-dependent developmental processes. These assays can be used to test the strength of newly found MEK1 mutations as well as for RASopathy and cancer mutations in other pathway components.

Z602 Hedgehog Signaling in Choroid Fissure Formation and Coloboma. *H. B. Gordon*, E. Wirik, B. Gaynes, K. M. Kwan. University of Utah, Salt Lake City, UT.

Optic cup morphogenesis is the process by which the nascent optic vesicle undergoes complex cell and tissue movements to transform into the optic cup—proper structure of which is critical for visual function. Coloboma is a structural defect of the eye arising from improper development of the choroid fissure—a transient yet critical optic cup structure through which retinal axons exit the eye and vasculature enters the eye. The Hedgehog (Hh) signaling pathway is a major effector of choroid fissure development: loss of function mutations in the Hh receptor *patched*, which lead to overactive Hh signaling, result in coloboma in zebrafish and humans. Despite the importance of the choroid fissure, we have a poor understanding of the cellular mechanisms underlying its morphogenesis.

Here we combine multidimensional timelapse imaging with custom cell tracking software to establish the cell movements underlying choroid fissure formation in zebrafish. Specifically, we mapped the origin and trajectories of cells of the nasal and temporal choroid fissure margins under wild type conditions, and we determined the precise movements that are disrupted in *patched2*^{tc294z} homozygous mutants. Our results indicate that cells that should be destined for the nasal margin of the choroid fissure stall in their migration, rendering them stuck in the optic stalk. To examine the migration defect at the cellular level, we marked cells using the photoactivatable fluorophore Kaede: in wild type embryos, cells exhibit a bipolar morphology while moving to form the choroid fissure. In *patched2* mutant embryos, these cells fail to maintain their initial bipolar morphology: they take on an aberrant multipolar morphology and cease movement within the optic stalk region. We conclude that overactive Hh signaling causes coloboma by disrupting cell movements underlying formation of the choroid fissure.

Having defined the cellular events underlying choroid fissure formation in wild type and *patched2* mutant embryos, we set out to determine the molecular mechanisms by which loss of *patched2* alters cell behavior. First, we asked in which cells overactive Hh signaling acts to disrupt choroid fissure cell movements. Surprisingly, using blastula cell transplantations, we find evidence for a non-cell autonomous role for overactive Hh signaling in controlling cell migration and morphology. This suggests interaction between migrating cells and the *patched2* mutant environment. We are now determining whether overactive Hh signaling due to loss of *patched2* is acting via canonical or non-canonical downstream signaling pathways to disrupt cell morphology and migration.

Z603 The role of the Nkd EF-hand in modulating Wnt signaling outputs. *A. N. Marsden*[1,2], S. W. Derry[1], T. A. Westfall[1], D. C. Slusarski[1,2]. 1) Department of Biology, University of Iowa, Iowa City, IA; 2) Interdisciplinary Graduate Program in Genetics, University of Iowa, Iowa City, IA.

The Wnt signaling network plays critical roles in development and is implicated in human disease. Wnts comprise a complex signaling network that, upon ligand binding, activates the phosphoprotein Dishevelled (Dvl), leading to distinct outputs including polarized cell movement (known as planar cell polarity, Wnt/PCP) and stabilization of the transcription factor β-catenin (Wnt/β-catenin). The mechanisms that determine a specific output are not completely understood, especially because they share receptors and cellular effectors, such as Naked-cuticle (Nkd), a Dvl-interacting protein. The Nkd protein contains a myristoylation domain and an EF-hand, a putative calcium binding domain. Genetic evidence in *Drosophila* demonstrates that Nkd acts as a Wnt/β-catenin antagonist, while in contrast, Nkd modulates both branches of Wnt signaling in vertebrates. We hypothesize that the specialized role of Nkd in *Drosophila* is due to a disrupted EF-hand that cannot not bind calcium. Indeed, this change is unique to *Drosophila* and is not present in closely related insects. To test the role of the Nkd EF-hand in Wnt signal integration, we created Nkd with a neutralized EF-hand, as well as a *Drosophila*-like EF-hand, and manipulate Nkd activity in the zebrafish. Using a combination of biochemical and functional assays, we identified a requirement for the Nkd EF-hand in Wnt/PCP but not in Wnt/β-catenin transcriptional outputs. We demonstrate that the *Drosophila*-like Nkd antagonizes Wnt/β-catenin more robustly than zebrafish Nkd. The EF-hand of Nkd is similar to the EF-hand of a known calcium binding protein, Recoverin, a myristoyl-swtich protein that shuttles between the membrane and the cytoplasm depending on its calcium bound state. Consistently, we observe that Nkd^{WT} shows localization changes in the calcium fluxing DFCs versus calcium quiescent cells but not the mutant forms. The Nkd EF-hand may serve to interpret the physiology of a cell receiving multiple cues and provides mechanistic insight into Wnt signal integration in vivo.

Z604 Glycolysis meets Fgf signaling: The glycolytic enzyme PGK1 is required non-autonomously for Fgf-dependent specification of otic neurons in zebrafish. *B. B. Riley*, H. Kantarci, K. Hofstetter. Texas A&M University, College Station, TX.

We conducted a pilot screen in zebrafish to identify ENU-point mutations that alter production of neurons of the statoacoustic ganglion (SAG), which innervates the inner ear. Two SAG-deficient mutations were recovered, termed *sagd1* and *sagd2*. Both are recessive lethal mutations that show no overt morphological defects but both strongly reduce subsets of SAG neurons. *sagd1* mutants, for example, show a specific deficiency in vestibular neurons required for balance, whereas auditory neurons develop normally. Whole-genome sequencing revealed that *sagd1* affects the glycolytic enzyme Pgk1 (Phosphoglycerate kinase-1). Targeted disruption of *pgk1* using CRISPRs yields an identical phenotype. Surprisingly, it appears that Pgk1 acts non-autonomously to promote efficient Fgf signaling. Fgf is normally required for specification of SAG neuroblasts, with vestibular neuroblasts forming first, followed by auditory neuroblasts. Although expression of known Fgf ligands appears normal in *sagd1* mutants, analysis of Fgf-reporters shows that the early phase of Fgf signaling required for vestibular neuroblasts is impaired. Fgf signaling later recovers to support normal development of auditory neuroblasts. Analysis of genetic mosaics shows the requirement for Pgk1 is non-cell autonomous, suggesting that Pgk1 acts outside the cell to facilitate Fgf's role in SAG specification. Other recent studies have shown that Pgk1 is often secreted to perform various "moonlighting" functions required for normal

development, as well as for efficient metastasis of certain aggressive forms of cancer. Because misexpression of Fgf8 from an inducible transgene does not rescue the *sagd1* phenotype, we speculate that secreted Pgk1 directly or indirectly modifies the extracellular matrix to promote efficient Fgf signaling. Experiments are ongoing to determine how Pgk1 influences the Fgf pathway.

Z605 Shh promotes direct interactions between epidermal cells and osteoblast progenitors to shape regenerated zebrafish bone. *K. Stankunas*, B. Armstrong, A. Henner, S. Stewart. University of Oregon, Eugene, OR.

A major challenge of regenerative medicine is to coax therapeutic stem cells to restore both form and function to injured tissues and organs. Zebrafish provide a vertebrate model that impeccably regenerates lost or damaged tissue by innate mechanisms that precisely control the proliferation, differentiation, and position of injury-induced progenitor cells. For example, Hedgehog/Smoothened (Hh/Smo) signaling in progenitor osteoblasts (pObs) is implicated in the re-establishment of stereotypically branched ossified rays during fin regeneration. Using a photoconvertible patched2 reporter line, we resolve active Hh/Smo output to a narrow distal fin regenerate zone comprising pObs and neighboring migratory basal epidermal cells. Hh/Smo activity is driven by epidermal Sonic hedgehog a (Shha) rather than pOb-derived Indian hedgehog a (Ihha), which instead uses non-canonical signaling to support bone maturation. Using high-resolution imaging and BMS-833923, a uniquely effective Smo inhibitor, we show that Shha/Smo promotes fin ray branching by escorting pObs into split groups that mirror transiently divided clusters of Shha-expressing epidermis. Epidermal cellular protrusions directly contact pObs only where an otherwise occluding Laminin B1A-containing basement membrane remains incompletely assembled. These intimate interactions coupled with epidermal movements progressively generate physically separated pOb pools that then continue regenerating independently to collectively form a now branched bony ray.

Z606 A genetic mechanism to sense and respond to enhanced cellular sphingosine levels during development. *T. Evans*, K. Mendelson, T. Hla. Weill Cornell Medical College, New York, NY.

The lipid mediator sphingosine-1-phosphate (S1P) plays multiple critical roles during embryogenesis. The earliest known function is for heart tube formation, revealed by the *mil* mutant, which is caused by a defective S1P receptor gene (*s1pr2*). S1P can only be generated by phosphorylation of a sphingosine precursor, and only one sphingosine kinase gene (*sphk2*) is expressed during zebrafish embryogenesis. Therefore, we generated *sphk2* mutants to determine if there are earlier or receptor-independent functions for S1P. A maternal zygotic mutant for *sphk2* (*sphk2*^{MZ}) phenocopies *mil*, suggesting that *sphk2* transmits essential migrational cues to the precardiac mesoderm during formation of the heart tube. However, we also noticed a slight developmental delay, and that *sphk2*^{MZ} embryos have elevated sphingosine levels. Compared to wildtype embryos, mutant embryos are sensitive to exogenous treatment with sphingosine. This results in a gastrulation defect and early embryonic lethality, which is phenocopied by morpholino knockdown of *sphk2*. We considered that the phenotype could be caused by excessive sphingosine, rather than a lack of S1P, and that *sphk2*^{MZ} embryos might be depleting sphingosine by another mechanism. Indeed, we observed a striking increase in transcript levels of the ceramide synthase 2b gene (*cers2b*) in *sphk2*^{MZ} embryos, but not in morphants. The transcriptional response to increased sphingosine levels is recapitulated on a reporter regulated by the *cers2b* promoter, and we mapped the minimal sequences essential for the sphingosine response. This is the first report of a transcriptional sphingosine response element (SphRE). These results indicate that *sphk2*^{MZ} embryos up-regulate a salvage pathway for sphingosine turnover to protect embryos from enhanced sphingosine levels in the absence of Sphk activity.

Z607 Developmental origin of muscle-associated fibroblasts. *P. Huang*, R. Ma, K. Kocha. University of Calgary, Calgary, Alberta, CA.

Skeletal muscles control many of the essential functions that our bodies constantly perform such as walking, eating and breathing. Defects in muscle function, for instance muscular dystrophy, have profound consequences. Despite extensive studies on muscles, relatively little is known about how muscle-associated cells modulate muscle function. Recently, several types of non-muscle cells have been discovered to interact closely with muscle fibers and play important roles in muscle regeneration and degeneration. Using a zebrafish model, we aim to determine the embryonic origin and functions of muscle-associated fibroblasts. We hypothesize that a subset of muscle-associated fibroblasts originates from the sclerotome, a sub-compartment of the somite. Using lineage tracing, we showed that sclerotome-derived cells undergo stereotypic migration out of each somite to surround the notochord during early development. Hedgehog (Hh) signaling is required in multiple steps during sclerotome formation. Although the initial expression of sclerotome markers can be induced in the absence of Hh signaling, active Hh signaling is essential to maintain their expression in sclerotome-derived cells. Furthermore, cell tracing experiments demonstrated that Hh signaling is required for the migration of sclerotome-derived cells. Finally, using time-lapse imaging, we showed that sclerotome-derived cells contribute to muscle-associated fibroblasts including tenocytes. We are currently investigating the function of muscle-associated cells in muscle regeneration and degeneration.

Z608 Hepatic nuclear receptor 4 alpha mediates microbial control of host gene expression in the zebrafish digestive tract. *James M. Davison*[1,2], Ghislain Breton[3], John F. Rawls[2]. 1) Dept. of Molecular Genetics and Microbiology, Duke University, Durham, NC; 2) Dept. of Cell Biology and Physiology, University of North Carolina, Chapel Hill, NC; 3) Dept. of Integrative Biology and Pharmacology, University of Texas Health Sciences Center, Houston, TX.

Intestinal microbiota influence diverse aspects of host nutrient metabolism and immunity in part by controlling tissue-specific transcription of key host genes. However, the host transcriptional regulatory mechanisms mediating microbial control of host gene expression are poorly understood. Microbiota colonization in zebrafish and mice leads to significant reductions in intestinal epithelial expression of Angiopotein-like

protein 4 (*angptl4/fiaf*), a circulating inhibitor of lipoprotein lipase. We previously showed that a discrete DNA cis-regulatory module (CRM) at the zebrafish *angptl4* locus named in3.4 mediates microbial control of transcription in the intestinal epithelium. To identify transcription factors that might regulate in3.4 activity, we used an unbiased yeast 1-hybrid approach and discovered that members of the Hepatic nuclear factor 4 (Hnf4) family of nuclear receptor transcription factors specifically bind to in3.4. Site-directed mutagenesis of in3.4 in yeast 1-hybrid and zebrafish transgenesis assays confirmed the existence of two Hnf4 binding sites in in3.4. Using the CRISPR/Cas9 system, we made targeted mutations in the zebrafish *hnf4a* gene and found that in3.4 enhancer activity was significantly attenuated in the intestinal epithelium of *hnf4a* homozygous mutants. To test the requirement for *hnf4a* on host transcriptional responses to microbiota, we used RNA-seq to compare transcript levels in the digestive tracts of *hnf4a* mutant and wild-type zebrafish raised germ-free or colonized with a conventional microbiota. Zebrafish *hnf4a* mutants displayed reduced expression of genes involved in lipid biosynthesis and metabolism, and increased expression of genes involved in inflammation and response to bacteria. Strikingly, loss of *hnf4a* significantly altered the expression of over half of the 822 genes that displayed differential expression in response to microbiota colonization. Hnf4a is an ancient member of the nuclear receptor family with important known roles in intestinal and hepatic physiology. Our results establish a novel role for Hnf4a in mediating host transcriptional responses to intestinal microbiota, and provide new mechanistic insight into how animal hosts perceive and respond to microbial cues.

Z609 Deciphering the role of Isl1 in enteroendocrine cell differentiation. *M. Voz*, J. Pirson, D. Stern, V. Von Berg, L. Flasse, I. Manfroid, B. Peers. GIGA, Liege, BE.

The gastrointestinal tract contains the largest population of hormone-producing cells in the body. These enteroendocrine cells, scattered throughout the digestive epithelium, secrete over fifteen different hormones, regulating important physiological functions such as glycaemia, pancreatic secretion and food intake. Understanding enteroendocrine cell differentiation is essential for identifying future targets for common disease such as diabetes and obesity.

To get a comprehensive view of the formation of these cells, we determined the transcriptomic landscape of enteroendocrine cells through RNAseq analyses of 4 dpf FACS sorted *pax6b:GFP* enteroendocrine cells. We found that the vast majority of the hormones described to be expressed in the gastrointestinal tract of the mouse are also expressed in the zebrafish gut. This transcriptomic analysis also highlighted the expression in the gut of four hormones not yet reported to be expressed in enteroendocrine cells of any species. Furthermore, we noticed a high similarity between enteroendocrine and pancreatic endocrine cells as many transcription factors expressed in the pancreas are also expressed in the gut. Among them, the LIM transcription factor Isl1 labels only a subset of enteroendocrine cells. The null *isl1*^{sa0029} mutant displays a drastic and specific reduction of the expression of the hormones synthetized by the corresponding enteroendocrine cell types. In contrast, the expression of transcription factors, thought to be important for the formation of the enteroendocrine progenitor cells, like *ascl1a, sox4b and neurod1*, is not perturbed in the *isl1*^{sa0029} mutant. The transcriptomic comparison by RNAseq of *wt* and mutant *isl1*^{sa0029} embryos identified 530 differentially expressed genes and among them, only a very limited number of transcription factors. Altogether, this suggests that Isl1 controls the last steps of the differentiation process of specific enteroendocrine cells.

Z610 Liver-enriched gene 1, a glycosylated secretory protein, binds to FGFR and mediates an anti-stress pathway to protect liver development in zebrafish. *J. R. Peng*[1], M. J. Hu[1], Y. Bai[1], C. X. Zhang[2], F. Liu[2], Z. B. Cui[3], J. Chen[1]. 1) Zhejiang University, Hangzhou, Zhejiang, CN; 2) Institute of Zoology, CAS, Beijing, China; 3) Institute of Hydrobiology, CAS, Wuhan, China.

Unlike mammals and birds, teleost fish undergo external embryogenesis, and therefore their embryos are constantly challenged by stresses from their living environment. These stresses, when becoming too harsh, will cause arrest of cell proliferation, abnormal cell death or senescence. Such organisms have to evolve a sophisticated anti-stress mechanism to protect the process of embryogenesis/organogenesis. However, very few signaling molecule(s) mediating such activity have been identified. *liver-enriched gene 1* (*leg1*) is an uncharacterized gene that encodes a novel secretory protein containing a single domain DUF781 (domain of unknown function 781) that is well conserved in vertebrates. In the zebrafish genome, there are two copies of *leg1*, namely *leg1a* and *leg1b*. *leg1a* and *leg1b* are closely linked on chromosome 20 and share high homology but is differentially expressed. In this report, we generated two *leg1a* mutant alleles using the TALEN technique, then characterized liver development in the mutants. We show that *leg1a* mutant exhibits a stress-dependent small liver phenotype that can be prevented by chemicals blocking the production of reactive oxygen species. Further studies reveal that Leg1a binds to FGFR3 and mediates a novel anti-stress pathway to protect liver development through enhancing Erk activity. More importantly, we show that the binding of Leg1a to FGFR relies on the glycosylation at the 70th asparagine (Asn^{70} or N^{70}) and mutating the Asn^{70} to Ala^{70} compromised Leg1's function in liver development. Therefore, Leg1 plays a unique role in protecting liver development under different stress conditions by serving as a secreted signaling molecule/modulator.

Z611 Program number not assigned.

Z612 Wnt signaling is required for adult zebrafish kidney regeneration. *C. N. Kamei*[1], Y. Liu[1], N. A. Hukriede[2], I. A. Drummond[1,3]. 1) Massachusetts General Hospital, Charlestown, MA; 2) University of Pittsburgh, Pittsburgh, PA; 3) Harvard Medical School, Boston, MA.

Kidney regeneration in zebrafish occurs by repair of existing nephrons as well as by *de novo* generation of new nephrons from adult organ progenitor cells by neonephrogenesis. We report here that Wnt signaling plays an essential role in adult zebrafish kidney regeneration. Newly forming nephron condensates in the developing mesonephros as well as those formed in the adult in response to gentamicin injury express the Wnt receptor *frizzled 9b* (*fzd9b*) and the canonical Wnt target gene *lef1*. In the *Tg(lhx1a:GFP)* nephron progenitor reporter line, both individual

lhx1a-positive adult kidney progenitor cells and nephron condensates are specifically marked by expression of *fzd9b*. Canonical Wnt signaling reporter line *Tg(TCF/Lef-miniP:dGFP)* combined with EdU labeling shows distinct zones of hi vs low Wnt activity and proliferation in new nephron formation. Pharmacological blockade of Wnt signaling using IWR1 and IWP2 led to a decrease in *lhx1a*+ nephron condensates after injury. EdU labeling in *Tg(lhx1a:GFP)* fish after gentamicin injury reveals that newly forming condensates are actively proliferating and this proliferation is blocked by Wnt inhibition. *wnt9b* is strongly induced in collecting duct epithelia after injury, making it a strong candidate for a mediator of the regeneration response. Our results demonstrate an essential role for Wnt signaling in adult zebrafish kidney regeneration. Identification of *fzd9b* as a new marker of adult kidney progenitor cells opens new avenues to investigate their developmental origins and regenerative potential.

Z613 Gain-of-function mutations of *mau*/DrAqp3a influence zebrafish pigment pattern formation through the tissue environment. *Anastasia Eskova*[1], Rosa Garcia-Junco[2], Francois Chauvigné[3], Hans-Martin Maischein[4], Moritz Ammelburg[5], Joan Cerdà[3], Lars Kaderali[6], Christiane Nüsslein-Volhard[1], Uwe Irion[1]. 1) MPI for Developmental Biology, Tübingen, Germany; 2) Grupo de Investigación en Bioloxía Evolutiva (GIBE), Facultade de Ciencias e CICA, Universidade da Coruña, A Coruña, Spain; 3) IRTA-Institut de Ciències del Mar, Consejo Superior de Investigaciones Científicas (CSIC), 08003 Barcelona, Spain; 4) Current address: Max Planck Institute for Heart and Lung Research, Bad Nauheim, Germany; 5) Current address: Fish & Richardson's, Munich, Germany; 6) Universitätsmedizin Greifswald, Institut für Bioinformatik, Greifswald, Germany.

The characteristic striped pigment pattern in zebrafish is formed by three types of pigment cells: black melanophores, yellow xanthophores, and iridescent iridophores. The patterning process depends on self-organizing properties of pigment cells, as well as extrinsic cues. By now most of the known pigment pattern formation mutations in zebrafish act cell autonomously in pigment cells, and our knowledge of the patterning regulation by surrounding tissues is scarce.

Here, we describe four dominant missense mutations in *mau*/Aquaporin 3a (Aqp3a), which is one of the main aquaporins in zebrafish skin and epithelia, known to transport water, glycerol and some other solutes. All four mutations lead to a similar phenotype: although all three types of pigment cells are present in the skin, the mutants display irregularities and broken stripes. In addition, they have short fins with fewer, but normally sized, fin ray segments. Blastula transplantations indicate that all the pigment cells types of *mau* mutants are capable of forming a wild-type-like pattern, but the mutant tissue environment prevents them from doing so. CRISPR-Cas9 knock-out of *mau*, which leads to no phenotypic consequences, and experiments in *Xenopus* oocytes as well as expression of mutant variants of Aqp3a in mammalian cells and zebrafish embryos indicated that *mau* mutations are neomorphic and their effect is dose-dependent. Based on transcriptome analysis and visualization of calcium distribution in the tissues of *mau* and wild-type fish, we suggest calcium signaling as a factor influencing behavior of pigment cells and their communication with surrounding tissues.

Z614 Evidence for ECM-Sema3d interactions controlling skeletal regeneration in the fin. *M.Kathryn Iovine*, Jayalakshmi Govindan. Lehigh University, Bethleham, PA.

The extracellular matrix (ECM) is much more than an inert material surrounding cells. Rather, evidence suggests that the ECM provides instructional cues regarding the external environment. One way that the ECM may act is as a reservoir for growth factors. However, specific growth factor-ECM interactions are undescribed in many instances. Recent research in the Iovine lab has identified a novel growth factor-ECM interaction that contributes to skeletal morphogenesis during fin regeneration. The fin skeleton is comprised of multiple bony fin rays, and each fin ray is comprised of bony segments separated by joints. Our research on the *short fin* (*sof*) mutant revealed that the gap junction protein Connexin43 (Cx43) coordinates skeletal growth (cell proliferation) and patterning (specification of joints). To provide insight into how Cx43 influences these cell behaviors, we identified downstream mediators of Cx43 function. Included among the Cx43-dependent genes are the secreted signaling molecule Semaphorin3d (Sema3d) and the link protein Hyaluronan and Proteoglycan Link Protein 1a (Hapln1a). Sema3d serves as a secreted growth factor that stimulates signal transduction pathways that promote cell proliferation in blastemal cells and suppress joint specification in skeletal precursor cells. Hapln1a/link protein is a component of the extracellular matrix (ECM) that is known to stabilize interactions between hyaluronan (HA) and proteoglycans (such as Aggrecan and Versican). Prior studies demonstrated that both Sema3d and Hapln1a are molecularly and functionally downstream of Cx43, as knockdown of either recapitulates the *sof* phenotypes (i.e. reduced cell proliferation and short segments/premature specification of joints). Current findings demonstrate that *hapln1a* and *sema3d* interact genetically, suggesting that the Hapln1a and Sema3d gene products function in a common pathway to coordinate skeletal growth and patterning. Moreover, morpholino-mediated knockdown of Hapln1a leads to reduced HA, Aggrecan, and Sema3d protein in regenerating fins. These findings suggest that Hapln1a is needed to stabilize aggregates of HA and Aggrecan, which in turn are required to stabilize Sema3d protein. Therefore, Sema3d protein levels and Sema3d-based signal transduction depend on the presence of HA-Hapln1a-Aggrecan aggregates. Overexpression of Sema3d rescues Hapln1a-knockdown phenotypes, providing further evidence that Hapln1a and Sema3d functionally interact during fin regeneration. These results are the first to demonstrate that Sema3d function requires an intact Hapln1a-ECM. Moreover, these findings reveal tangible connections between the Hapln1a-ECM, Sema3d-dependent signal transduction, and skeletal morphogenesis.

Z615 Positional cloning of *cloche*, a gene that drives endothelial and hematopoietic lineage specification. *Didier Y. R. Stainier*[1,2], Sven Reischauer[1,2], Oliver Stone[1,2], Alethia Villasenor[1,2], Suk-Won Jin[1], Neil Chi[1], Marcel Martin[3], Miler T. Lee[4], Michele Marass[2], Ian Fiddes[1], Taiyi Kuo[1], Won-Suk Chung[1], Sherveen Salek[1], Robert Lerrigo[1], Jessica Alsiö[1], Shujun Luo[6], Björn Nystedt[7], Antonio J. Giraldez[4], Gary P. Schroth[5], Olov Andersson[5]. 1) Department of Biochemistry and Biophysics, University of California San Francisco, San Francisco, California, USA; 2) Max Planck

Institute for Heart and Lung Research, Bad Nauheim, Germany; 3) Science for Life Laboratory, Dept of Biochemistry and Biophysics, Stockholm University, Solna, Sweden; 4) Department of Genetics, Yale University School of Medicine, New Haven, Connecticut, USA; 5) Department of Cell and Molecular Biology, Karolinska Institutet, Stockholm, Sweden; 6) Illumina, San Diego, CA, USA; 7) Science for Life Laboratory, Dept of Cell and Molecular Biology, Uppsala University, Uppsala, Sweden.

Vascular and hematopoietic cells organize into specialized tissues during early embryogenesis to supply essential nutrients to all organs and thus play critical roles in development and disease. At the top of the hemato-vascular specification cascade lies *cloche*, a gene that when mutated in zebrafish leads to the striking phenotype of loss of most endothelial and hematopoietic cells with a substantial increase in overall cardiomyocyte numbers. While this mutant has been analyzed extensively to investigate mesoderm diversification and differentiation and continues to be broadly utilized as a unique avascular model, the isolation of the *cloche* gene has been challenging due to its telomeric location. Using a deletion allele of *cloche*, we identified several new *cloche* candidate genes within this genomic region, and systematically genome-edited each candidate. Through this exhaustive interrogation, we have finally identified the *cloche* gene and will report on its identity and further functional analysis.

Z616 Molecular asymmetry at electrical synapses – at the gap and beyond. *Adam Miller*[1], Alex Whitebirch[2], Arish Shah[2], Cecilia Moens[2]. 1) University of Oregon, Eugene, OR; 2) Fred Hutchinson Cancer Research Center, Seattle, WA.

Camillo Golgi and Santiago Ramón y Cajal famously argued over whether the nervous system was one big syncytium or instead a network of independent units. While it is clear that neurons are separate units as Cajal suggested, communication between neurons can occur directly, without chemical intermediary, at electrical synapses, akin to what Golgi envisioned. Electrical synapses are composed of gap junction (GJ) channels between neurons allowing for direct ionic and metabolic communication. Neuronal GJs are often thought to be simple, symmetric structures, with the same protein constituents on either side of the synapse. During GJ formation, both the pre- and postsynaptic neurons contribute hemichannels composed of hexamers of Connexin (Cx) protein to form functional channels between neurons. Despite this apparent simplicity, work from cell culture has found that GJs can contain multiple different Cx proteins and this can affect the functional properties of communication. In a forward genetic screen in zebrafish, which looked for mutations affecting electrical synapse formation in the Mauthner neural circuit, we identified the *Dis3* mutation that disrupts a homologue of mammalian *connexin36* (*cx36*). *cx36* is thought of as the main neuronal GJ gene due to its broad neuronal expression and extensive contributions to electrical synapses throughout the brain,. Through genome gazing we found that zebrafish have four orthologous cx36-like genes, *cx34a* (*Dis3*), *cx34b*, *cx35a*, and *cx35b*. To identify which Cxs were required we developed a CRISPR-based *in vivo* screen and found that only *cx34a* and *cx35a* were necessary for M electrical synapse formation. Using cell transplantations we found that *cx34a* is required exclusively postsynaptically, while *cx35a* is required exclusively presynaptically, for synaptogenesis. Additionally, the CRISPR screen identified a scaffolding molecule, *tjp1b*, that is necessary for electrical synaptogenesis and preliminary evidence suggests *tjp1b* is required exclusively postsynaptically. We conclude that vertebrate electrical synapses can be molecularly asymmetric at the level of the GJ proteins themselves. In addition, our preliminary evidence suggests that such asymmetries can extend beyond the channel to the larger proteome of the electrical synapse. Such asymmetries at the GJ and beyond suggest a molecular mechanism for generating functional asymmetry across the electrical synapse. Moreover, this work suggests that we are just starting to scratch the surface of electrical synapse complexity and future work will continue to reveal the richness of these structures at the molecular and functional level. Also, it hopefully allows Golgi to rest a bit easier.

Z617 Cell proliferation and differentiation are controlled by different Fgf downstream targets during sensory hair cell regeneration. *Mark E. Lush*, Scott Freeburg, Tatjana Piotrowski. Stowers Institute for Medical Research, Kansas City, MO.

Organ regeneration is a complex process involving integration of multiple cell signaling pathways. The zebrafish lateral line contains mechanosensory hair cells that respond to vibrations in the surrounding water and serve as a great model to study the development and regeneration of the auditory system. Lateral line hair cells are surrounded by at least two groups of support cells, which together form a structure called the neuromast. Unlike mammals, the sensory hair cells of the lateral line regenerate after damage. We have previously shown that hair cell regeneration requires Notch down regulation and Wnt-dependent proliferation of a resident support cell population. Other signaling pathways, such as Fgf are also expressed in mature neuromasts. Fgf signaling is required for lateral line development, as it is for the ear of mouse, chicken and zebrafish, but its role in regeneration has not been studied. RNASeq and in situ hybridization analyses show that *fgf3* and *fgf10a*, and the receptors *fgfr1a* and *fgfr2* are expressed in naïve neuromasts and are immediately down regulated after hair cell death. This finding suggests that down regulation of Fgf signaling maybe required to initiate hair cell regeneration. Indeed, in *fgf3* mutants, hair cell regeneration is enhanced due to increased support cell proliferation. This finding is significant, as it suggests that Fgf3 manipulations might be important for inducing regeneration in the mammalian ear. Interestingly, *fgf10a* mutants do not show differences in regeneration potential, suggesting that different *fgf* ligands may activate different receptors or downstream signaling pathways in the lateral line. Increased hair cell regeneration and proliferation is mimicked by low dose treatment with pharmacological inhibitors of Fgf receptors. Surprisingly, high doses of Fgf inhibitors block regeneration, even though proliferation is still increased. These findings suggest that proliferation and hair cell differentiation are regulated via different receptors or downstream targets. Inhibition of Notch signaling during regeneration also leads to increased cell proliferation suggesting that Notch and Fgf might interact. However, Notch inhibition and the *fgf3* mutation affect different downstream genes. Also, in *fgf3* mutants or after inhibition of Fgf signaling, proliferation is even increased in undamaged neuromasts, which is not the case after Notch inhibition. These results show that Notch and *fgf3* initiate divergent downstream signaling events to inhibit

proliferation during homeostasis and regeneration. Therefore, the combined downregulation of these pathways should be explored in mammals to trigger proliferation and regeneration.

Z618 Cilia genes play differing roles in hair cells. *T. Stawicki*[1], L. Hernandez[1], R. Esterberg[1,2], T. Linbo[1], K. Owens[1,2], A. Shah[3], C. Moens[3], E. Rubel[1,2], D. Raible[1,2]. 1) University of Washington, Seattle, WA; 2) Virginia Merrill Bloedel Hearing Research Center, Seattle, WA; 3) Fred Hutchinson Cancer Research Center, Seattle, WA.

Hair cells contain a single primary cilium early in development, known as the kinocilium. This cilium is usually lost in auditory hair cells but maintained in vestibular hair cells. Hair cells also possess rows of actin-based stereocilia that are responsible for responses to mechanical stimuli. The kinocilium is located adjacent to the tallest stereocilia row. In hair cells, the primary function of cilia genes is believed to be in the development of stereocilia polarity indirectly through regulation of kinocilia. Through a screen for mutations that confer resistance to aminoglycoside-induced hair cell death we have identified a number of mutations in cilia genes, showing a novel role of cilia genes in hair cells. We found that mutations in the intraflagellar transport (IFT) genes *ift88, traf3ip, dync2h1* and *wdr35* all lead to strong resistance to neomycin-induced hair cell death. Mutations in the transition zone genes *cc2d2a, mks1,* and *cep290* lead to more moderate protection. These two classes of genes appear to play different roles in aminoglycoside-induced hair cell death. Mutations in IFT, but not transition zone, show a reduction of neomycin uptake into hair cells, loss of kinocilia and a reduction in control hair cell numbers. The individual IFT genes appear to differently affect hair cells as well, as mutations in *ift88, traf3ip* and *dync2h1,* but not *wdr35* show a reduction in hair cell FM1-43 uptake, a process dependent upon mechanotransduction activity. This does not appear to be due to defects in stereocilia morphology. Future work will focus on delineating the mechanisms behind the diverse roles cilia genes play in hair cells.

Z619 The Agrin receptor Lrp4 promotes peripheral nerve regeneration through a novel, MuSK-independent pathway. *K. D. Gribble*[1], J. Bremer[1], J. Y. Kuwada[2], M. Granato[1]. 1) University of Pennsylvania, Philadelphia, PA; 2) University of Michigan, Ann Arbor, MI.

Following injury, peripheral nerves reestablish neuromuscular connections with their developmental targets. While the molecular pathways that govern peripheral nerve development and neuromuscular synapse formation are well understood, it is unclear whether the same pathways are reemployed to promote regeneration. For example, neuromuscular synapses require the evolutionarily conserved Agrin-Lrp4-MuSK signaling pathway to cluster acetylcholine receptors (AChRs) beneath motor axon terminals, yet their *in vivo* role in peripheral nerve regeneration has not been examined. To determine whether this pathway is re-utilized during regeneration, we used a previously established assay that enables us to transect spinal motor nerves and continuously monitor regeneration in live, intact zebrafish (Rosenberg et al., 2012).

We find that animals harboring a TALEN-induced *lrp4* null allele display defects in neuromuscular synapse formation, while motor axon growth and guidance is unaffected. In contrast, after nerve transection, these axons largely fail to regrow to their muscle targets. Using the same assay, we find that the obligate Lrp4 co-receptor MuSK, which is essential for neuromuscular synapse development, is dispensable for motor axon regeneration, demonstrating that Lrp4 promotes axon regeneration through a MuSK-independent pathway. Moreover, using a second *lrp4* mutant allele we find that the Lrp4 transmembrane domain, while critical for neuromuscular synapse development, is dispensable for axon regeneration, consistent with the idea that Lrp4 promotes regeneration through a novel, tether-independent pathway. Restoring *lrp4* expression only to muscle cells in animals otherwise lacking *lrp4* rescues neuromuscular synapse development but does not rescue motor axon regeneration, suggesting that Lrp4 acts in another cell type to promote axon regeneration. We will present ongoing efforts to further characterize this novel MuSK-independent pathway through which Lrp4 promotes peripheral nerve regeneration.

Z620 *pregnancy-associated plasma protein-aa* (*pappaa)* mediates the development and function of distinct retinal circuits. *Andrew Miller*[1], Holly Howe[2], Scott Friedle[2], Marc Wolman[2]. 1) Neuroscience Training Program, University of Wisconsin-Madison; 2) Department of Zoology, University of Wisconsin-Madison.

Neural circuits must rapidly detect and interpret sensory stimuli to accurately guide behavior. In the visual system, retinal circuits begin to distinguish light and dark stimuli at synapses between photoreceptors and ON- and OFF-bipolar cells, respectively. Bipolar cells develop without a need for other retinal cell types or activity, and thus, are thought to rely on autonomous gene expression. Through a genetic screen, we identified an essential role for *pregnancy-associated plasma protein-aa* (*pappaa)* in visually guided behaviors mediated by OFF-bipolar cells. By characterizing the identified *pappaa* mutant, our work describes the first role for *pappaa* in the development of neural circuits and identifies a critical factor in the formation and function of the retinal circuits that specifically guide behavioral responses to dark stimuli.

Despite a grossly normal retina and retinotectal projection, larvae harboring nonsense mutations in *pappaa* show an almost complete failure to initiate an O-bend response to sudden darkness or to turn away from a gradient of darkness. In contrast, *pappaa* mutant larvae facing a light target accurately swim towards the light. Together, the mutants' behavior suggest that the ON-bipolar retinal pathway is intact, but the OFF-bipolar pathway mediating dark induced behavior is disrupted. Indeed, selective pharmacological stimulation of the OFF-bipolar pathway in *pappaa* mutants restores their dark induced behavioral deficiencies. *pappaa* acts as a metalloprotease to stimulate local IGF1 signaling. To gain insight into when *pappaa-IGF1* signaling is required for dark induced visually guided behavior, we used genetic and pharmacological approaches to manipulate IGF1 signaling in *pappaa* wild type and mutant larvae. Induction of a transgenic, dominant negative IGF1R during temporally restricted periods indicated that IGF1 signaling is critical during the period of retinal synaptogenesis for larvae to respond to dark stimuli. Moreover, stimulation of IGF1 signaling in *pappaa* mutants during this stage improved dark induced behavior in the mutants. Throughout this period of retinal synaptogenesis, *pappaa* is exclusively expressed by bipolar cells in the retina and not in the tectum, consistent with a developmental role for *pappaa* in OFF-bipolar cell synaptic connections. Currently, we are performing ERG recordings and high-

resolution anatomical analyses of OFF-bipolar cells to identify the specific requirement of PAPPAA-IGF1 signaling for OFF-bipolar cell synaptic function.

Z621 CachD1 is a novel type I transmembrane protein that regulates the development of habenular asymmetry in zebrafish. *A. F. Faro*[1], H. Stickney[1,3], G. Powell[1,2], G. Gestri[1], I. Leek[1], P. Henriques[1], R. Young[1], T. Hawkins[1], F. Cavodeassi[1], Q. Schwartz[1], G. Wright[2], D. Raible[3], S. Wilson[1]. 1) University College London, London, GB; 2) Wellcome Trust Sanger Institute, Cambridge , GB; 3) University of Washington, Seattle, US.

Structural and functional nervous system asymmetries are conserved throughout the animal kingdom and have been shown to impact cognition and behavior. Despite their prevalence, our understanding of the genetic bases for the development of brain asymmetries is still sparse.

One of the most amenable structures in which to study developmental mechanisms underlying central nervous system asymmetries is the epithalamus. In zebrafish, this structure is composed of the medially positioned pineal complex and the bilateral asymmetric habenular nuclei.

We isolated the *rorschach* (*rch)* mutant through a mutagenesis screen to identify mutations disrupting habenular asymmetry. Mutant embryos display left-isomerized symmetric habenula yet viscera asymmetries are unaffected. Positional cloning has shown that *rch* mutants have a V1122D substitution in the *cache domain containing 1* gene which encodes a novel type I transmembrane protein. The lesion occurs in the gene's single transmembrane domain and disrupts protein localization.

We have performed a screen to identify binding partners for Cachd1 and found that it physically interacts with Frizzled receptors – key components of the Wnt signaling pathway. This is consistent with previous studies showing Wnt signaling has a pivotal role in the elaboration of asymmetries within the habenular nuclei. Temporal and spatial activation of a reporter for β-catenin dependent transcription and expression of *axin2*, a bona-fide Wnt target gene, are affected in the developing diencephalon of *rch* mutants, while epistasis studies show that Cachd1 acts upstream of Axin1.

Taken together these findings suggest that Cachd1 modulates the activation status of Wnt signaling in habenula progenitors to regulate allocation of left-right character to habenular neurons.

Z622 New pathways required for zebrafish brain Left-Right asymmetry and bilateral symmetry. *Michael Rebagliati*[1,2], Merlin Lange[3], Anastasiia Aleksandrova[4], Laure Bally-Cuif[3], Olivier Pourquié[1,2,4,5,6]. 1) Institut de Génétique et de Biologie Moléculaire et Cellulaire (IGBMC), CNRS (UMR 7104), Inserm U964, Université de Strasbourg, Illkirch, France; 2) Stowers Institute for Medical Research, Kansas City, Missouri, USA; 3) Paris-Saclay Institute for Neuroscience, CNRS, Univ Paris Sud, Université Paris-Saclay, Gif-sur-Yvette, France; 4) Department of Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, Kansas, USA; 5) Howard Hughes Medical Institute, Kansas City, Missouri, USA; 6) Department of Genetics, Harvard Medical School and Department of Pathology, Brigham and Woman's Hospital, Boston, Massachusetts, USA.

Nodal, a member of the TGF-B superfamily of growth factors, controls visceral organ Left-Right (LR) asymmetry in vertebrates as well as some epithalamic brain LR asymmetries that exist in zebrafish but are not apparent in mammals. But the pathways that operate broadly in all vertebrates to establish brain Left-Right asymmetry and lateralized behaviors are unknown. At least some of these unknown pathways are thought to be Nodal-independent, since lateralized behaviors like handedness and right ear hearing advantage are normal in human patients with Left-Right reversed Nodal signaling. We present evidence that the Rere protein is part of a Nodal-independent pathway needed for zebrafish brain laterality. Rere is a nuclear receptor co-regulator required for optimal Retinoic Acid signaling as well as for modulating other pathways. In humans, *RERE* is a candidate risk gene for schizophrenia and autism spectrum disorders. We find that heterozygosity for the *rerea* mutation, *bab*^{tb210}, disrupts normal population-level laterality of adult zebrafish females without disrupting other behavioral parameters and without perturbing *nodal* (*southpaw*) expression and function. We compare these results to the results for population-level laterality of adult zebrafish males heterozygous for the *bab*^{tb210} allele. We also examine the role of *rerea* and other factors in establishing and/or maintaining bilateral symmetry in the zebrafish embryo. Finally, we discuss the relevance of our results for human-specific traits like handedness and language, as well as the implications for human congenital diseases and neurodevelopmental disorders like schizophrenia and autism, which often have disruptions of bilateral symmetry and/or of LR asymmetry.

Z623 Roundabout2 and exotosin-like 3 promote target specific peripheral nerve regeneration *in vivo*. *P. L. Murphy*, J. Isaacman-Beck, C. Syrett, M. Granato. University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania.

Following injury, axons of the peripheral nervous system regenerate, but only a small fraction reinnervate their original targets. Instead, regenerating axons grow too slowly to reach their original targets before supporting Schwann cells degenerate, and/or axons grow in the wrong direction and innervate inappropriate targets. To decipher the cellular and molecular mechanisms that guide regenerating axons toward their original targets, we study target selective regeneration of spinal motor nerves in larval zebrafish. Each nerve is composed of a ventral and a dorsal branch that diverge at a stereotyped choice-point. We have recently shown that following laser mediated nerve transection, axons of the dorsal branch select their original trajectory with high fidelity (>70%; Issacman-Beck et al, Neuron, 2015). Moreover, we find that *slit1a* mRNA is upregulated in denervated Schwann cells distal to the lesion site, suggesting a role for slit/robo signaling in directing regenerating dorsal axons. To directly probe the *in vivo* role of slit/robo signaling, we examined mutants for the slit receptor *robo2*. While *robo2* appears dispensable for motor nerve development, we find that regenerating dorsal axons in *robo2* mutants frequently (45%) fail to regenerate towards their original targets, and instead extend along ectopic trajectories. Interestingly, we find that exotosin-like 3 (*extl3*) mutants display a

similar phenotype with higher frequency (61%). *Extl3* modifies heparan sulfate proteoglycans, which are known to stabilize slit/robo binding. Finally, we find that *robo2* and *extl3* function specifically in directing axons of the dorsal nerve branch – regenerating axons of the ventral nerve branch select their original targets with high fidelity in *robo2* and *extl3* mutants. Thus, *extl3* and *robo2* mediate pathway specific axon guidance during peripheral nerve regeneration. We will present ongoing work on how *robo2* and *extl3* promote target specific regeneration.

Z624 MECP2-IGF1 signaling determines how neural circuits interpret sensory information. *Nicholas Santistevan*, Cole Gilsdorf, Marc Wolman. University of Wisconsin - Madison, Madison, WI.

Rett Syndrome (RTT) is an X-linked neurodevelopmental, autism spectrum disorder that affects 1 in 10,000 females and is characterized by motor and cognitive impairment. RTT is caused by dysfunction of the *methyl-CpG-binding protein 2 (mecp2)* gene; a transcriptional regulator known to promote neuron development and function. Despite *mecp2's* association with RTT, it remains poorly understood how MECP2 activity influences circuits comprised of various neuron types to control distinct aspects of behavior.

Larval stage behavioral analyses revealed that *mecp2* mutants exhibit reduced prepulse inhibition (PPI) of the acoustic startle response (ASR); and therefore, indicate a critical role for *mecp2* in the ASR circuits' ability to interpret sensory information. Stimulus interpretation is often impaired in autism spectrum disorders, but is typically attributed to sensory or motor defects. Notably, the *mecp2* mutants show normal acoustic sensitivity, execute a normal ASR, and habituate to repetitive acoustic stimulation; and therefore, indicate a specific, central role for *mecp2* in regulating PPI. Consistent with published reports, inhibition of NMDA-type glutamate receptors or GABA-A receptors reduces PPI in wild type and strengthens the *mecp2* mutants' PPI deficit. In contrast, stimulation of glutamatergic or GABAergic signaling in *mecp2* mutants reverses their PPI deficit. These results, coupled with our understanding of the ASR circuit's cellular makeup, suggest that *mecp2* is required for a feedforward inhibitory microcircuit that uses glutamate and GABA to suppress Mauthner neuron activity and hence, drive PPI. Imaging of this feedforward microcircuit revealed developmental defects in *mecp2* mutants.

As a transcriptional regulator, *mecp2* likely influences circuit development and function by activating or suppressing specific genes. For example, *mecp2* stimulates expression of *igf1*; a vital regulator of circuit formation and function. IGF1 recently became a promising therapeutic target for RTT when IGF1 stimulation was found to reverse motor defects in *MECP2* deficient mice. To determine whether *mecp2* acts through IGF1 signaling to control PPI, we combined genetic and pharmacological manipulations to attenuate and stimulate IGF1 signaling in wild type and *mecp2* mutants, respectively. Induction of a dominant negative *igfr1a* reduced PPI, suggesting that IGF1R activity is required for PPI. Stimulation of IG1R signaling in *mecp2* mutants was sufficient to improve PPI in *mecp2* mutants. Together, these results support the model that *mecp2* promotes IGF1 signaling to regulate how a neural circuit interprets sensory information.

Z625 Selenoprotein H is an essential regulator of redox homeostasis that cooperates with p53 in development and tumorigenesis. *A. Cox*[1], A. Kim[1], D. Saunders[1], A. Tsomides[1], K. Hwang[1], K. Evason[2], J. Heidel[3], K. Brown[4], M. Yuan[4], E. Lien[4], B. Lee[1,5], S. Nissim[1], B. Dickinson[6], S. Chhangawala[7], C. Chang[8,9], J. Asara[4], Y. Houvras[7], V. Gladyshev[1,12], W. Goessling[1,10,11,12]. 1) Brigham and Women's Hospital, Harvard Medical School, Boston, MA; 2) University of Utah, Salt Lake City, UT; 3) Oregon State University, Corvallis, OR; 4) Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; 5) Korea University, Seoul, South Korea; 6) University of Chicago, Chicago, IL; 7) Weill Cornell Medical College and New York Presbyterian Hospital, NY; 8) Howard Hughes Medical Institute; 9) University of California, Berkeley, Berkeley, CA; 10) Harvard Stem Cell Institute, Cambridge, MA; 11) Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA; 12) Broad Institute of MIT and Harvard, Cambridge, MA.

Selenium is an essential micronutrient, known for its cancer prevention properties, that is incorporated into a class of selenocysteine-containing proteins (selenoproteins). The human genome encodes 25 selenoproteins which play diverse roles in redox homeostasis, thyroid hormone metabolism, endoplasmic reticulum function and selenium transport. Selenoprotein H (*seph*) is a recently identified nucleolar oxidoreductase with DNA-binding properties whose function is not well understood. Here, we discover that *seph* is an essential gene regulating organ development in zebrafish. Metabolite profiling by targeted LC-MS/MS demonstrated that SepH deficiency impaired redox balance by reducing the levels of ascorbate and methionine, whilst increasing methionine sulfoxide. Transcriptome analysis revealed that SepH deficiency induced an inflammatory response and activated the p53 pathway. Consequently, loss of *seph* rendered larvae susceptible to oxidative stress and DNA damage. Finally, we demonstrate that *seph* interacts with p53 deficiency in adulthood to accelerate gastrointestinal tumor development. Overall, these studies establish that *seph* regulates redox homeostasis and suppresses DNA damage. We hypothesize that SepH deficiency may contribute to the increased cancer risk observed in cohorts with low selenium levels.

Z626 Single-cell imaging of normal and malignant cell engraftment into optically clear immune deficient zebrafish. *Q. Tang*[1,2,3,4], J. C. Moore[1,2,3,4], N. Torres Yordán[4,5], F. E. Moore[1,2,3,4], E. G. Garcia[1,2,3,4], R. Lobbardi[1,2,3,4], A. Ramakrishnan[1,2,3,4], A. Anselmo[6,7], R. I. Sadreyev[6,7], D. M. Langenau[1,2,3,4]. 1) Molecular Pathology, Massachusetts General Hospital, Charlestown, MA 02129, USA; 2) Center for Regenerative Medicine, Massachusetts General Hospital, Boston, MA 02114, USA; 3) Cancer Center, Massachusetts General Hospital, Charlestown, MA 02129, USA; 4) Harvard Stem Cell Institute, Cambridge MA 02139, USA; 5) Harvard University, Cambridge, MA, 02138, USA; 6) Department of Molecular Biology, Massachusetts General Hospital, Boston, MA 002114, USA; 7) Department of Genetics, Harvard Medical School, Boston, MA 02115, USA.

Cell transplantation into immune deficient mice has revolutionized the fields of regenerative medicine and cancer biology. Yet, tools to facilitate direct visualization of the dynamic processes underlying carcinogenesis, tumor progression and metastasis *in vivo* remain limited. Here, we develop optically clear, immune deficient zebrafish that have mutations in *recombination activating gene 2* (*rag2)*, *DNA-dependent*

protein kinase (*prkdc*) and *janus kinase 3* (*jak3*). RNA sequencing and single-cell transcriptional profiling of the blood showed that *rag2* hypomorphic mutant zebrafish lack T cells, while *prkdc* deficiency resulted in lack of mature T and B cells and *jak3* in T and putative Natural Killer (NK) cells. While all three mutant lines engraft fluorescent-labeled normal and malignant cells, only the *prkdc* mutant fish reproduced as homozygotes and survived injury following tail fin clip and cell transplantation. Engraftment into optically clear, *prkdc*-mutant adult zebrafish facilitated dynamic live cell imaging of muscle regeneration, repopulation of muscle stem cells within their endogenous niche, and muscle fiber fusion at single-cell resolution. Serial imaging approaches also uncovered stochasticity in fluorescent-labeled leukemia regrowth following competitive cell transplantation into *prkdc*-mutant fish, providing refined models to assess clonal dominance and progression in the zebrafish. Our experiments provide an optimized and facile transplantation model, the *casper*-strain *prkdc* mutant fish, for efficient engraftment and direct visualization of fluorescent-labeled normal and malignant cells at single-cell resolution.

Z627 Dynamics of innate immunity guided tumor cell motility *in vivo*. *Minna Roh-Johnson*[1], Arish Shah[1], Susumu Antoku[2], John Condeelis[3], Cecilia Moens[1]. 1) Fred Hutchinson Cancer Research Center, Seattle, WA, USA; 2) Columbia University, New York, NY, USA; 3) Albert Einstein College of Medicine, Bronx, NY, USA.

During cancer progression, interactions between tumor cells and immune cells play critical roles in the initiation of metastasis. In malignant melanoma, it is unclear how a melanocyte transitions from a premalignant nevus to an invasive tumor cell, and which components in the tumor microenvironment regulate this switch. A major limitation to understanding this switch *in vivo* is the lack of genetically tractable model systems that are amenable to high-resolution imaging of both the tumor and its microenvironment with cellular resolution. We have overcome this obstacle by directly visualizing tumor cells and their interactions with stromal cells in zebrafish. We found that injecting either human or zebrafish melanoma cells results in metastasis from the site of injection. Live imaging of the primary tumor revealed that tumor cells respond to contact with host macrophages by extending more actin-rich protrusions than those tumor cells not in contact with macrophages. Further, depleting host macrophages reduced melanoma metastasis. To reveal signaling pathways involved in macrophage-induced melanoma progression, we performed a reverse genetic *in vivo* screen for increased or decreased metastasis and identified *myd88*, a key regulator in the inflammatory response pathway, which functions downstream of Toll-Like Receptors. Depleting embryos of *myd88* decreased macrophage motility and recruitment of macrophages to the primary tumor, and inhibited melanoma metastasis. We further found that expression of constitutively active Myd88 in macrophages was sufficient to induce increased melanoma metastasis. Macrophages form long, thin, and dynamic protrusions to communicate with tumor cells *in vivo*, and our preliminary experiments suggest that these processes may be necessary for tumor cell metastasis. We are currently testing this hypothesis, and whether expression of Myd88 affects melanoma metastasis through the formation of these dynamic protrusions in macrophages, with high-resolution imaging approaches *in vivo*.

Z628 *tp53*-deficient zebrafish models of Malignant Nerve Sheath Tumor, Leukemia, Angiosarcoma, Rhabdomyosarcoma, and Germ cell tumors. *Myron Ignatius*[1], Finola Morre[1], Madeline Hayes[1], Qin Tang[1], Riadh Lobbardi[1], Sophia Reeder[1], Alexander Jin[1], Patrick Blackburn[2], Eleanor Chen[3], Petur Nielsen[1], Stephen Ekker[2], David Langenau[1]. 1) Harvard Medical School/Department of Pathology, Massachusetts General Hospital, Boston, MA; 2) Mayo Clinic, Rochester, MN; 3) Department of Pathology, University of Washington, Seattle, WA.

Individuals with Li-Fraumeni Syndrome inherit a mutant *TP53* allele and are predisposed to developing a wide range of cancers including sarcomas and leukemia. *TP53* is also somatically inactivated in more than half of all sporadic human cancers. Despite the well-studied role of p53 in cancer, mechanistic insights into how specific loss-of-function mutations regulate tumorigenesis are not clearly understood. Here, we have generated a new full-null tp53 deletion allele in syngeneic CG1 strain zebrafish. Two TALEN pairs were created to efficiently delete the entire 11kb locus. *tp53-/-* null zebrafish, lack p53 protein, are viable, survive at Mendelian ratios and can develop tumors as early as three months of age. In contrast to existing dominant-negative *tp53* alleles available in the zebrafish that develop MPNSTs with long latency, *tp53null* animals spontaneously develop lymphomas, MPNSTs, angiosarcomas, and germ cell tumors. 40% of null animals develop tumors within the first year of life (n=53 of 134). MPNSTs, lymphomas, and angiosarcomas could efficiently be transplanted into syngeneic recipient fish (2-4x10^4 cells/fish injected intraperitoneally). To visualize tumor growth *in vivo*, we next generated tp53null; Tg(Ubi-GFP) CG1 strain syngeneic zebrafish and transplanted tumors from fish with lymphoma into matched recipients. Transplanting either the kidney marrow or bulk tumor cells from diseased fish resulted in robust engraftment and seeding of leukemic cells to the kidney marrow, thymus, and spleen. Leukemia cells had atypical myeloid cell features, suggestive of myeloid leukemia. *tp53* is mutationally inactivated in 50% of human embryonal rhabdomyosarcomas (ERMS). To assess a role for *p53* in regulating ERMS growth, onset, tumor-propagating potential, and metastasis; we created zebrafish that were transgenic for kRASG12D and p53 loss. Self-renewal was unaffected in comparing kRASG12D tumors with and without p53 (n=3 tumors per genotype; p=0.66). By contrast, *tp53*null ERMS were more invasive and had elevated metastatic potential both in the primary and transplant settings (n=6 tumors per group). Taken together, we have developed a full null for the *tp53* allele in the zebrafish and show that null mutants develop a spectrum of tumor types with short latency and high penetrance. We are currently sequencing tumors generated in *tp53 null* mutants to perform comparative genomics with human tumors.

Z629 Investigating novel non-oncogene targets for cancer therapies. *Joan Heath*[1], Kimberly Morgan[1], Karen Doggett[1], Lachlan Whitehead[1], Stephen Mieruszynski[1], Zhiyuan Gong[2]. 1) Walter and Eliza Hall Institute of Medical Research, Parkville, Melbourne, Victoria, AU; 2) Department of Biological Science, National University of Singapore.

Somatic mutations in the *RAS* oncogenes are the most common activating lesions in human cancers. These mutations are frequently associated with poor responses to standard cancer therapies and over the last three decades intense effort has been directed towards the

identification of compounds that can bind to RAS and alter its activity. As yet this has been met with little success and mutant RAS is considered by many to be 'undruggable'. Thus identifying therapeutic vulnerabilities in cancer cells that harbour *RAS* mutations has the potential to greatly improve outcomes for patients with cancers of diverse tissue origin.

Chronic activation of RAS signalling places persistently high metabolic demands on cells to sustain robust cancer cell growth. This prompted us to investigate whether the genes underlying the endodermal phenotypes in a collection of zebrafish mutants we identified in the LiverPlus screen (1) might be required to sustain the rapid growth and proliferation of cells fuelled by oncogenic Ras expression. We have shown that these genes are required to maintain the high proliferative activity of intestinal epithelial cells and hepatocytes between 3 and 7 days of zebrafish development, and that they encode components of multi-subunit complexes that perform essential cellular functions, including transcription, RNA processing and nuclear pore assembly. Using a doxycycline inducible zebrafish hepatocellular carcinoma (HCC) model (2), we identified genetic interactions between oncogenic *kras*^{G12V} and three of our cloned zebrafish genes. Transgenic zebrafish, Tg(fabp10:rtTA2s-M2;TRE2:EGFP-Kras^{G12V}), hereafter TO(kras^{G12V}), were exposed to doxycycline (20µg/ml) at 2 dpf and again at 5 dpf, prior to analysis of liver volume at 7 dpf using two photon microscopy. This regime produced robust expression of EGFP-Kras^{G12V} and hepatocyte overgrowth, resulting in a 7.5 fold increase in the volume of the liver between 3-7 dpf. When this experiment was conducted with TO(kras^{G12V}) larvae carrying heterozygous mutations in genes important for U12-type splicing, ribosome biogenesis or nuclear pore formation, liver volume in this HCC model was reduced by up to 50%. Since these heterozygous mutations do not affect normal liver development, these experiments suggest that drugs designed to disrupt U12-type splicing, ribosome biogenesis and nuclear pore formation may provide a therapeutic window that could be exploited clinically to restrict the growth of cancer cells without affecting normal proliferative compartments.

Z630 Chemical genetic approach identifies role of proton sensing GPR68 in modulation of migration in melanoma. *C. H. Williams*[1], C. C. Hong[1,2]. 1) Vanderbilt University, Nashville, TN; 2) Vanderbilt Univ. Med. Ctr., Nashville, TN.

Increased glycolysis resulting in local acidification is a hallmark of cancer. However, the mechanisms by which this acidification affects cellular behaviors such as migration are not understood. We report the discovery of Ogremorphin (OGM) a first in class inhibitor of GPR68 in a phenotypic zebrafish screen. The target of OGM was identified through a cheminformatics and receptor profiling, and validated genetically with knock down technology. GPR68 plays a critical role in neural crest development during zebrafish development. Furthermore, hiPSC derived Neural crest stem cell migration is inhibited by OGM. GPR68 is proton sensitive GPCR that is maximally active at ~pH6.6, and is upregulated in melanoma cell lines. We show that melanoma are more motile in acidic media. Furthermore, the increased migratory capacity is attenuated by OGM, which attenuates the formation of focal adhesions complexes. Taken together, the data suggests that pH mediated signaling is a critical component during embryonic development, and that GPR68 represents a possible novel pharmacological target for melanoma metastasis.

Z631 Zebrafish Pediatric Brain Tumor Modeling for Pre-clinical Drug Screening. *R. Stewart*[1], K. Modzelewska[1], E. Boer[1], R. Miles[1], J. Schiffman[1], A. Huang[2]. 1) Huntsman Cancer Institute, University of Utah, Salt Lake City, UT; 2) Department of Pediatrics, Hospital for Sick Children, University of Toronto, ON, Canada.

Primitive Neuroectodermal Tumors (PNETs) represent the largest group of malignant brain tumors in children, with similar cellular histology but diverse clinical phenotypes/outcomes. The most common PNET is medulloblastoma located in the cerebellum, while more rare and aggressive PNET sub-groups located throughout the central nervous system (CNS) are collectively called CNS-PNETs. Due to the rarity of CNS-PNETs the cell of origin and oncogenic pathways driving their formation is not known, hindering development of targeted therapeutic options for these patients, who have an overall survival of ~ 20%. Recent genomic expression profiling has defined three CNS-PNETs subtypes: neural, oligoneural and mesenchymal. By modeling CNS-PNET gene signatures in zebrafish, we have generated the first animal model of oligoneural CNS-PNET. We show that activation of NRAS signaling in Sox10-expressing zebrafish embryonic cells with *p53*-deficiency generate oligoneural CNS-PNETs with conserved histological and molecular features to human CNS-PNETs, including activated MAPK/MEK signaling. We have also performed orthotopic brain tumor transplantation and drug-screening assays to show MEK activity is essential for oligoneural CNS-PNET tumor growth *in vivo*, and survival of human PNET cells *in vitro*. Thus, MEK inhibitors represent the first targeted therapy option for children with oligoneural CNS-PNETs.

Z632 Dissecting the mechanism of oncogenic glutamate receptor signaling in melanocytes and melanoma. *A. Neto*, C. Ceol. Program in Molecular Medicine and Department of Molecular, Cellular and Cancer Biology, UMass Medical School, Worcester, MA.

Glutamate signaling has been shown to have a role in melanoma progression, in part through activating mutations in the metabotropic glutamate receptor 3 (GRM3) gene. We hypothesize that altered glutamate signaling affects the development and function of melanocytes, endowing these cells with properties important for melanoma progression. By expressing mutant GRM3 variants in developing zebrafish melanocytes, we determined how oncogenic GRM3 variants affected these cells. In embryonic melanocytes oncogenic GRM3 mutants disrupted trafficking of melanosomes, causing their aggregation in the cell body. Wild-type GRM3 had no effect on melanosome distribution. Melanosomes are trafficked in a cAMP-dependent manner, and drugs that directly or indirectly increase cAMP levels were able to rescue the melanosome phenotype of oncogenic GRM3-expressing melanocytes. Our data indicate that oncogenic GRM3 variants dysregulate cyclic AMP (cAMP) signaling, a heretofore unknown role for these oncogenes. Preliminary data in cultured melanoma cells indicate that oncogenic GRM3

leads to a reduction of cAMP levels as compared to wild-type GRM3 or EGFP. cAMP signaling has been implicated in melanoma progression and drug resistance, and our data show that oncogenic properties of GRM3 could be mediated, at least in part, by alterations in cAMP signaling.

Z633 GDF6-induced BMP signaling promotes melanoma progression by reawakening a pro-survival neural crest identity. *Craig Ceol*[1], Arvind Venkatesan[1], Rajesh Vyas[1], Karen Dresser[1], Sharvari Gujja[1], Sanchita Bhatnagar[1], Sagar Chhangawala[2], Camilla Borges Ferreira Gomes[3], Haulin Simon Xi[1], Christine Lian[3], Yariv Houvras[2], Yvonne Edwards[1], April Deng[1], Michael Green[1]. 1) UMass Medical School, Worcester, MA; 2) Weill Cornell Medical College, New York, NY; 3) Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Oncogenomic studies have revealed genetic alterations that affect tumor progression. Included amongst these alterations are focal and broad recurrent copy number variations (CNVs). Identifying driver genes, which are responsible for disease progression, in broad CNVs is challenging as these regions harbor many bystander passenger genes that are altered due to their proximity to drivers. To enrich for driver genes in regions of CNV we performed comparative oncogenomics with human and zebrafish melanomas. Coupling this approach with transcriptome analyses, we identified the BMP factor *GDF6* as a novel melanoma oncogene. *GDF6* is specifically expressed in melanomas and not melanocytes, and its knockdown led to melanoma cell death. Enforced expression of *GDF6* promoted melanoma growth in an autochthonous zebrafish model as well as in mouse xenografts. Genetic epistasis analysis indicated that *GDF6* acts via *SMAD1* to aid in melanoma cell survival. Transcriptome analyses of melanoma cells with GDF6/BMP modulation found that a major role of *GDF6* is to regulate expression of genes important in neural crest development. Indeed, *GDF6* and its orthologs are expressed in the neural crest, where they regulate cell survival and fate specification. Mechanistic analyses determined that *GDF6* acts via suppression of the neural crest factor *SOX9,* which is an established pro-apoptotic factor in melanomas. To extend the relevance of these findings to the clinic we analyzed melanoma patient samples and found that nearly 80% of human melanomas express high levels of GDF6 and have an active BMP pathway. Furthermore, GDF6 expression correlated with poor overall survival of melanoma patients. We found that treatment with a BMP pathway small molecule inhibitor, DMH1, attenuated melanoma growth in mouse xenografts. Our findings have established that GDF6-dependent BMP signaling endows melanoma cells with a pro-survival, neural crest identity. Additionally, our results highlight GDF6 and BMP pathway components as novel targets for therapeutic intervention of melanomas.

Z634 Humanising the zebrafish liver shifts metabolic profiles, improves pharmacokinetics of CYP3A4 substrates and couples with development of fluorescent screening biomarkers. *T. J. Carney*[1,4], K. L. Poon[1], X. Wang[1], A. Ng[1], W. H. Goh[1], S. G. P. Lee[3], Z. Zhao[4], M. Al-Hadawwi[1], S. Fowler[2], H. Wang[1], P. Ingham[1,4], C. McGinnis[2]. 1) Institute of Molecular and Cell Biology (IMCB), A*STAR, Singapore; 2) Roche, Basel, Basel, Switzerland; 3) Genome Institute of Singapore, A*STAR, Singapore; 4) Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore.

Understanding and predicting whether new drug candidates will be safe in the clinic is a critical hurdle in pharmaceutical development, that relies in part on absorption, distribution, metabolism, excretion (ADME) and toxicology studies in vivo. Through toxicity and absorption analyses of a number of drugs, we find that zebrafish is generally predictive of drug toxicity although liver microsome assays reveal specific differences in metabolism of compounds between human and zebrafish livers, likely resulting from the divergence of the Cytochrome P450 superfamily between species. To reflect human metabolism more accurately, we generated a transgenic “humanized” zebrafish line that expresses the major human Phase I detoxifying enzyme, CYP3A4, in the liver. Here, we show that this humanized line shows an elevated metabolism of CYP3A4 specific substrates compared to wild-type zebrafish. The generation of this first described humanized zebrafish liver, suggests such approaches can enhance the accuracy of the zebrafish model for toxicity prediction. We subsequently utilise transcriptomics to identify highly upregulated genes as biomarkers of toxic responses in this model, finding candidate biomarkers which recurred in multiple treatments. Through promoter isolation and fosmid recombineering, eGFP reporter transgenic zebrafish lines were generated and showed a dose and time dependent induction in endodermal organs to reference drugs and an expanded drug set. Thus through integrated transcriptomics and transgenic approaches, we have developed a humanised zebrafish toxicity assay coupled with parallel independent zebrafish *in vivo* screening platforms able to predict organ toxicities of preclinical drugs.

Z635 Missing heritability for orofacial clefing identified through dissection of the gene regulatory network governing zebrafish periderm differentiation. *Robert A. Cornell*[1], Huan Liu[1], Elizabeth Leslie[2], Zhonglin Jia[1], Tiffany Smith[1], Mekonen Esthete[3], Azeez Butali[1], Martine Dunnwald[1], Jacquline Hecht[4], Ramat O. Braimah[3], Babatunde Aregbesola[3], Milliard Deribew[3], Mine Koruyucu[5], Figen Seyman[5], Lian Ma[6], Javier Enríquez de Salamanca[7], Seth M. Weinberg[2], Lina Moreno[1], Jeffrey Murray[1], Mary Marazita[2]. 1) University of Iowa, Iowa City, IA; 2) University of Pittsburgh, Pittsburgh, PA; 3) Addis Ababa University, Addis, Ethiopia; 4) University of Texas Health Science Center at Houston, Houston, TX; 5) Istanbul University, Istanbul, Turkey; 6) Peking University, Beijing, China; 7) Universitario Niño Jesús, Madrid, Spain.

Non-syndromic orofacial clefting, including cleft lip with or without cleft palate (CL/P), and cleft palate alone (CP), is a common disorder with a strong genetic underpinning. Genome-wide association studies (GWAS) have detected common variants associated with risk for this disorder. However, GWAS only explain a portion of the overall heritability for orofacial clefting; much of the risk is conferred by unidentified rare sequence variants. It is unclear what genes harbor such variants. In addition, the mechanistic basis of risk conferred by common, risk-associated variants (i.e., identified by GWAS) is unknown. Here we present our approach to both challenges using zebrafish. Most patients with Van der Woude orofacial clefting syndrome have mutations in *IRF6,* encoding Interferon Regulatory Factor 6, an essential member of the gene regulatory network (GRN) governing differentiation of periderm. Genes encoding other members of this GRN are candidates to harbor rare variants that confer risk for orofacial clefting. With epistasis experiments, we found that Krüppel-like factor 17 (Klf17) and Grainyhead-like 3

(Grhl3) both act downstream of Irf6 in the zebrafish periderm GRN. Klf17 expression is absent from mammalian oral epithelium, but a close homologue, Klf4, is expressed in this tissue and is required for the differentiation of epidermis. Chromosome configuration capture and reporter assays indicate that IRF6 directly regulates an oral-epithelium enhancer of *KLF4*. Next, we sequenced *KLF4* in approximately non-syndromic CL/ P cases and controls. Two patient-derived *KLF4* variants disrupted periderm differentiation upon forced expression in zebrafish embryos. Thus, rare variants of KLF4 account for some of the missing heritability for non-syndromic CL/P. Further, we detected rare coding variants of *GRHL3* in some patients with Van der Woude syndrome, and found they disrupted periderm differentiation in zebrafish, explaining some of the missing heritability for this disorder. Finally, a recent GWAS revealed that a common coding variant of *GRHL3* is associated with risk for non-syndromic CP. This variant, but not other common coding variants of *GRHL3*, has dominant negative activity in zebrafish. In sum, functional studies in zebrafish helped identify rare variants that contribute to the missing heritability for syndromic and non-syndromic forms of CL/P, and identified the mechanistic basis of a common variant associated with risk for non-syndromic CP.

Z636 Linking cilia motility and cerebrospinal fluid flow to the etiopathogenesis of adolescent idiopathic scoliosis. *D. T. Grimes*[1*], C. Boswell[2], N. F. C. Morante[1], R. M. Henkelman[2], R. D. Burdine[1], B. Ciruna[2]. 1) Princeton University, Princeton, NJ; 2) Hospital for Sick Children, University of Toronto, Canada.

Adolescent idiopathic scoliosis (AIS), a disease characterized by 3D spinal curvatures, afflicts 2-3% of children worldwide. However, the underlying biological basis for this disease has remained unknown. Recently, the teleost fish have emerged as robust models of AIS. Using zebrafish, we have discovered that spinal curves are caused by loss of motile cilia function, which in turn results in defective CSF flow. Human AIS can be caused by mutations in *PTK7*, and we find that cilia/CSF flow defects are also the basis of spinal curves in *ptk7* zebrafish mutants. Thus, we propose that AIS can be caused by disruptions to CSF flow, providing a novel mechanism for this prevalent disease. We also provide evidence that spinal curves can be partially rescued by restoring cilia motility after curve onset, opening potential therapeutic avenues.

Z637 Macrophage epithelial reprogramming underlies mycobacterial granuloma formation and promotes infection. *Mark Cronan*[1], Rebecca Beerman[1], Allison Rosenberg[1], Matthew Johnson[1], Joseph Saelens[1], Stefan Oehlers[1], Dana Sisk[1], Kristen Jurcic Smith[1], Le Trinh[2], Scott Fraser[2], John Madden[1], Joanne Turner[3], Jason Stout[1], Sunhee Lee[1], David Tobin[1]. 1) Duke University, Durham, NC; 2) University of Southern California, Los Angeles, CA; 3) The Ohio State University, Columbus, OH.

Mycobacterium tuberculosis infection in humans triggers formation of granulomas, tightly organized immune cell aggregates that are the central structure of tuberculosis. Infected and uninfected macrophages interdigitate, assuming an altered, flattened appearance. Although pathologists have described these changes for over a century, the molecular program that mediates this transition is unclear. We find that mycobacterial infection results in macrophage induction of canonical epithelial molecules, driving formation of granulomas. Using the zebrafish-*Mycobacterium marinum* model and intravital microscopy, we identify bona fide adherens junction formation between granuloma macrophages and nucleation of this process via interactions with host epithelium. Macrophage-specific disruption of E-cadherin function results in disordered granuloma formation, decreased bacterial burden, and enhanced long-term survival of infected animals, suggesting that a canonical mycobacterial granuloma may be fundamentally host-detrimental. In human clinical samples, granuloma macrophages are similarly transformed, paralleling E-cadherin-dependent mesenchymal-to-epithelial transitions in development and cancer, processes that profoundly regulate cell fate and function.

Z638 Metabolic stress induces Ripk3- and macrophage-dependent β-cell death in a zebrafish model of insulin resistance. *W. Chen*, L. Maddison. Vanderbilt University School of Medicine, Nashville, TN.

Insulin resistance can be compensated by increased insulin secretion and increased β-cell number. However, long-term insulin resistance can lead to β-cell failure, β-cell death and the development of type 2 diabetes. With its genetic, chemical, and anatomical tractability, zebrafish is poised to help elucidate the mechanisms that are involved in β-cell failure and death. To this end, we generated a transgenic model with skeletal muscle-specific insulin resistance, zMIR. When challenged with repeated exposure to overnutrition, the β-cell number in zMIR larvae initially increased as in control animals, but rapidly declined after the third exposure, indicating that β-cells of zMIR fish are more susceptible to metabolic stress. The β-cell loss can be prevented by anti-diabetic drugs and chemical chaperones. This β-cell loss was not through apoptosis or de-differentiation, but through necroptosis. Consistent with this, inhibitors of necroptosis protected the β-cells. Furthermore, genetic ablation of *ripk3*, a key regulator of necroptosis, also protected the β-cells. The β-cell loss coincided with islet macrophage infiltration in the zMIR animals. Macrophage depletion by clodronate liposomes or by genetic ablation of *irf8* protected β-cells. Interestingly, necroptosis inhibitors also suppressed macrophage infiltration. These data support a model in which metabolic stress triggers proinflammatory necroptosis of a small subset of β-cells in zMIR fish and the consequent macrophage infiltration causes death of additional β-cells.

Z639 Genetically encoded apolipoprotein reporters illuminate lipoprotein dynamics in the larval zebrafish. *Steven A. Farber*[1,2], James H. Thierer[2], Jessica P. Otis[1]. 1) Carnegie Institution for Science, Baltimore, MD; 2) Johns Hopkins U., Baltimore, MD.

Lipoproteins are central players in lipid transport and metabolism, and aberrations in the localization and metabolism of lipoproteins are major contributing factors to the growing incidence of metabolic disease. While it remains true that high serum high-density lipoprotein (HDL) cholesterol levels are associated with better clinical outcomes, recent data has called into question the cell biological and physiological functions attributed to HDL. The larval zebrafish has emerged as an excellent model for human metabolic disease, and has also proven a useful tool for monitoring lipid trafficking *in vivo* using fluorescent lipid analogs. Here we describe the development of optical reporters of lipoprotein

biology that provide an unprecedented opportunity to monitor lipoprotein dynamics at subcellular resolutions in a live vertebrate. Two distinct approaches were designed to address specific questions related to (1) HDL biology and (2) the diverse classes of non-HDL particles including low density lipoprotein (LDL) **Approach 1**: Zebrafish have two *apoa-I* genes that we determined are expressed in the yolk syncytial layer, intestine and liver. To study APOA-I (forms HDL) of hepatic vs. intestinal origin *in vivo*, we created transgenic zebrafish expressing fluorescently labeled human or zebrafish APOA-I driven by liver- or intestine-specific promoters. Confocal microscopy of live larvae reveals APOA-I-mCherry fluorescence in the circulation and in specific tissues and subcellular domains. Fluorescent puncta were observed in the apical late endosomal/lysosomal compartment of intestinal enterocytes of larvae expressing hepatic APOA-I-mCherry. APOA-I-mCherry of intestinal origin colocalizes with late endosomal markers in liver hepatocytes. These data suggest previously unappreciated roles for the intestine and liver in the recycling and/or degradation of ApoA-I of hepatic origin and intestinal origin, respectively. **Approach 2:** Apolipoprotein B (ApoB) is the obligate structural component of LDL and elevated levels are linked to metabolic diseases. Despite its heritability, many of the genetic factors governing LDL levels remain uncharacterized. We have developed zebrafish carrying a luciferase reporter fused to the ApoB gene locus to produce a tagged ApoB protein. We can now rapidly quantify ApoB levels in individual larvae, and have used the reporter to determine the size distribution of LDL particles using a novel native-PAGE approach. In summary, we have developed a fluorescent reporter for tracking the intracellular and inter-organ trafficking of HDL and a chemiluminescent reporter of LDL lipoprotein particles to support a chemical screen for regulators of LDL biology. To our knowledge, this is the first time tissue-specific apolipoprotein transport has been visualized *in vivo* in any vertebrate.

Z640 Estrogens Suppress a Behavioral Phenotype in Zebrafish Mutants of the Autism Risk Gene, CNTNAP2. *Ellen J. Hoffman*[1], Katherine J. Turner[2], Joseph M. Fernandez[1], Daniel Cifuentes[1,3], Marcus Ghosh[2], Sundas Ijaz[1], Roshan A. Jain[4,5], Fumi Kubo[6], Brent R. Bill[7,8], Herwig Baier[6], Michael Granato[4], Michael J. F. Barresi[9], Stephen W. Wilson[2], Jason Rihel[2], Matthew W. State[1,10], Antonio J. Giraldez[1]. 1) Yale University, New Haven, CT; 2) University College London, London, UK; 3) Boston University School of Medicine, Boston, MA; 4) University of Pennsylvania, Philadelphia, PA; 5) Haverford College, Haverford, PA; 6) Max Planck Institute of Neurobiology, Martinsried, Germany; 7) University of California, Los Angeles, CA; 8) The University of Texas at Tyler, Tyler, TX; 9) Smith College, Northampton, MA; 10) University of California, San Francisco, San Francisco, CA.

Autism spectrum disorders (ASD) are a group of devastating neurodevelopmental syndromes that affect up to 1 in 68 children. Despite advances in the identification of ASD risk genes, the mechanisms underlying ASD remain unknown. Homozygous loss-of-function mutations in *Contactin Associated Protein-like 2* (*CNTNAP2*) are strongly linked to ASD. We generated zebrafish mutants of *cntnap2* and conducted pharmacological screens to identify phenotypic suppressors. We found that zebrafish *cntnap2* mutants display GABAergic deficits particularly in the forebrain and sensitivity to drug-induced seizures. High-throughput behavioral profiling identified nighttime hyperactivity in *cntnap2* mutants, while pharmacological testing revealed dysregulation of GABAergic and glutamatergic systems. Finally, we found that estrogen receptor agonists elicit a behavioral fingerprint anti-correlative to that of *cntnap2* mutants and showed that the phytoestrogen biochanin A specifically reverses the mutant behavioral phenotype. These results identify estrogenic compounds as phenotypic suppressors and illuminate novel pharmacological pathways with relevance to autism. We are utilizing pharmaco-behavioral profiling of zebrafish mutants of multiple ASD risk genes to identify relevant biological pathways and potential pharmacological candidates for further evaluation.

Z641 Macrophage-mediated thrombus dissolution is rate limiting during vascular repair. *H. Clay*[1], I. Lam[1], J. Shavit[2], S. R. Coughlin[1]. 1) UCSF, San Francisco, CA; 2) University of Michigan, Ann Arbor, MI.

Vessel repair requires the coordinated actions of multiple cell types in order to effect coagulation, inflammation, repair of the injured endothelium, and resolution of inflammation. Using zebrafish embryos, we demonstrate that the dynamics of the thrombus, leukocytes, and the vascular endothelium can be tracked and quantified using real-time microscopy over the entire course of injury repair. This system affords a unique opportunity to study vascular repair *in vivo* using genetic and pharmacological manipulation. We find that macrophage influx to the wound site is coincident with thrombus dissolution, and that while initial macrophage recruitment is independent of thrombus formation, persistence at the wound site after re-establishment of blood flow requires local fibrin deposition, and macrophages are actively involved in clearance of the thrombus. Depletion of macrophages, but not neutrophils, leads to increased healing times secondary to the increased persistence of the thrombus at the wound site. Taken together, our data demonstrate that thrombus removal is rate-limiting during vascular repair and that macrophages are required during this process.

Z642 A story in translation: Phosphoinositide signaling and angiogenesis. *B. M. Weinstein*[1], A. N. Stratman[1], C. M. Mikelis[3], Z. Wang[3], O. M. Farrelly[1], M. F. Miller[1], S. A. Pezoa[1], V. N. Pham[1], D. Castranova[1], A. E. Davis[1], T. M. Kilts[4], G. E. Davis[5], J. S. Gutkind[3], W. Pan[1,2]. 1) Division of Developmental Biology, National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD, 20892; 2) Key Laboratory of Stem Cell Biology, Institute of Health Sciences, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences & Shanghai Jiao Tong University School of Medicine, Shanghai, China, 200031; 3) Oral and Pharyngeal Cancer Branch, National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, MD 20892; 4) Craniofacial and Skeletal Diseases Branch, National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, MD, 20892; 5) Department of Medical Pharmacology and Physiology, School of Medicine, Dalton Cardiovascular Research Center, University of Missouri, Columbia, MO 65212.

Anti-angiogenic therapies have been regarded as one of the most promising new approaches for combating cancer, but they have yet to fulfill this promise. In large part, this is because of the ability of tumors to evade or overcome these therapies by up-regulating pro-angiogenic

cytokines. We report a new approach to inhibit angiogenesis - targeting recycling of the rate-limiting substrate used for transduction of VEGF-dependent angiogenic signaling. Beginning with zebrafish mutants identified in a genetic screen and using zebrafish, cell culture, and mouse tumor models we show that this new approach has the potential to result in a uniquely effective inhibition of tumor angiogenesis, since increased VEGF stimulation, rather than overcoming the inhibition, only results in faster consumption of the limiting substrate and more rapid and complete inhibition of angiogenesis.

Z643 LSD1-dependent shutdown of *etv2* promotes hematopoietic differentiation in hemangioblasts. *M. Kobayashi*, J. Tamaoki, Y. Fuse, M. Takeuchi. University of Tsukuba, Tsukuba, Ibaraki, JP.

The hemangioblast is a progenitor cell with the capacity to give rise to both hematopoietic and endothelial progenitors. Currently, the regulatory mechanisms underlying hemangioblast formation are being elucidated, whereas those controllers for the selection of hematopoietic or endothelial fates still remain a mystery. To answer these questions, we screened for zebrafish mutants that have defects in the hemangioblast expression of *gata1*, which is never expressed in endothelial progenitors. One of the isolated mutants, *it627*, showed not only down-regulation of hematopoietic genes but also up-regulation of endothelial genes. We identified the gene responsible for the *it627* mutant as the zebrafish homolog of Lys-specific demethylase 1 (LSD1/KDM1A). Surprisingly, the hematopoietic defects in *lsd1*^{it627} embryos, both erythropoiesis and ectopic myelopoiesis, were rescued by the gene knockdown of the Ets variant 2 gene (*etv2*), an essential regulator for hemangioblast development. Our results suggest that the LSD1-dependent shutdown of *etv2* expression may be a significant event required for hemangioblasts to initiate hematopoietic differentiation.

Z644 Growth Differentiation Factor 6 (GDF6) promotes vascular quiescence by maintaining stable endothelial cell adherens junctions. *S. Krispin*, A. N. Stratman, C. H. Melick, B. M. Weinstein. NICHD,NIH, Bethesda, MD.

The assembly of a functional vascular system requires coordinated signaling between various growth factors and receptors. The bone morphogenetic protein (BMP) receptors and their BMP ligands have important functions during embryonic vessel assembly and maturation. These crucial roles have been demonstrated in vascular disorders such as hereditary hemorrhagic telangiectasia (HHT). However, the identity of the responsible ligands and mechanism of action are still not clear. Growth Differentiation factor 6 (GDF6=BMP13), is a highly conserved BMP ligand. A previous report has suggested a role for gdf6a (one of the two zebrafish GDF6 homologues) in vascular integrity, however, the mechanism of gdf6a action was not clear. We find that the zebrafish gdf6a mutants demonstrate massive trunk hemorrhage in 20% of 48hpf mutants, with increased vascular permeability in non-hemorrhaging mutants. We also find that GDF6 is a negative regulator of VEGFA/VEGFR2 signaling. Loss of GDF6 in zebrafish leads to increased VEGFA, causing destabilization of VE-Cadherin and weakening of endothelial cell adherence junctions. The role of GDF6 is conserved in human endothelial cells; GDF6 siRNA mediated knockdown in human umbilical vein endothelial cells (HUVEC) resulted in increased monolayer permeability, VEGFA/VEGFR2 increase accompanied by an increased phosphorylation of VE-Cadherin and decrease in total levels of VE-Cad as seen in gdf6a^{s327} mutants. GDF6 activity is mediated preferentially through the BMPR1B-BMPR2 complex upstream of Smad2/3. Understanding how GDF6 affects vascular integrity will help provide insights into hemorrhage and associated pathologies in humans.

Z645 Embryonic hematopoiesis in vertebrate somites gives rise to definitive hematopoietic stem cells. *A. Meng*[1], J. Qiu[1], X. Fan[2], Y. Wang[1], H. Jin[1], Y. Song[1], Y. Han[3], S. Huang[1], Y. Meng[1], F. Tang[3]. 1) School of Life Sciences, Tsinghua University, Beijing, CN; 2) College of Life Sciences, Peking University, Beijing, CN; 3) College of Biological Sciences, China Agricultural University, Beijing, CN.

Hematopoietic stem cells (HSCs) replenish all types of blood cells. It is debating whether HSCs in adults solely originate from the aorta-gonad-mesonephros (AGM) region, more specifically, the dorsal aorta, during embryogenesis. Here we report that somite hematopoiesis, a previously unwitnessed hematopoiesis, can generate definitive HSCs (dHSCs) in zebrafish. We noticed that in several transgenic lines, in which GFP is expressed in somites during embryonic development, embryos and adults carry hematopoietic cells in the circulation. We established Tg(foxc1b:EOS) transgenic line, which expresses the photoconvertible fluorescence reporter EOS in somites. By photoactivating EOS in specific somite areas, we found that a subset of cells within the forming somites emigrate ventrally and mix with lateral plate mesoderm-derived primitive hematopoietic cells before the blood circulation starts. These somite-derived hematopoietic precursors and stem cells (sHPSCs) subsequently enter the circulation and colonize the kidney of larvae and adults. RNA seq analysis reveals that sHPSCs express hematopoietic genes with sustained expression of many muscle/skeletal genes, which is in contrast to absent or low expression of muscle/skeletal genes in gata1a-positive primitive hematopoietic precursors. Embryonic sHPSCs transplanted into wild-type embryos expand during growth and survive for life time with differentiation into various hematopoietic lineages, indicating self-renewal and multipotency features. In contrast, transplanted gata1a-positive primitive hematopoietic precursors cannot survive over 9 days in the recipients. Therefore, we propose that dHSCs can also originate from embryonic somites.

Z646 RUNX1-independent development of HSC and definitive hematopoiesis in zebrafish. *P. Liu*, Blake Carrington, B. Carrington, M. Jones, S. Wincovitch, R. Sood. NHGRI/NIH, Bethesda, MD.

The transcription factor RUNX1 is required for the emergence of definitive hematopoietic stem cells (HSCs) from the hemogenic endothelium during mouse embryonic development. Consequently, *Runx1* knockout mouse embryos lack all definitive blood lineages and cannot survive past embryonic day 13. Previously we found that mutating the only *runx1* homologue in zebrafish also resulted in deficiency of definitive blood cells during embryogenesis. However, the zebrafish *runx1* mutants, which carried an ENU-induced nonsense mutation in *runx1* (*runx1*$^{W84X/W84X}$),

were able to recover from a larval "bloodless" phase and develop to fertile adults with multi-lineage hematopoiesis (Sood et al., Blood 2010), suggesting that definitive hematopoiesis can develop without RUNX1. To confirm this finding and to further study the underlying mechanism, we generated three new *runx1* mutants: two mutations in exon 4 of *runx1* (a deletion of 8 bp, *runx1*$^{del8/del8}$, and a deletion of 25 bp, *runx1*$^{del25/del25}$) that truncate the runt-homologous domain; and a large deletion of exons 3 through 8 (*runx1*$^{del(e3-8)/del(e3-8)}$), which removes most coding region of *runx1,* using the TALEN and CRISPR-Cas9 technologies. All three new *runx1* mutants failed to develop definitive hematopoiesis during early embryonic development. Time-lapse recordings with confocal microscopy revealed no emergence of *c-myb*$^{+}$ HSCs from the ventral wall of dorsal aorta in the runx1 mutant embryos at 48 hours post fertilization. However, a second wave of HSCs emerged that led to circulating blood cells between 15 and 20 days post fertilization. Eventually, about 40% of the *runx1* mutants developed to fertile adults with circulating blood cells of multi-lineages. Taken together, our data strongly suggests for a RUNX1-independent mechanism for HSC formation and definitive hematopoiesis.

Z647 TopBP1 Governs Hematopoietic Stem/Progenitor Cells Survival in Zebrafish Definitive Hematopoiesis. *Weijun Pan*[1*], Lei Gao[1], Yi Zhou[2], Leonard I. Zon[2]. 1) Key Laboratory of Stem Cell Biology, Institute of Health Sciences, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences & Shanghai Jiao Tong University School of Medicine, Shanghai, China; 2) Stem Cell Program, Hematology/Oncology Program at Children's Hospital Boston and Dana Farber Cancer Institute, Harvard Medical School, Boston, Massachusetts, United States of America.

In vertebrate definitive hematopoiesis, nascent hematopoietic stem/progenitor cells (HSPCs) migrate to and reside in proliferative hematopoietic microenvironment for transitory expansion. In this process, well-established DNA damage response pathways are vital to resolve the replication stress, which is deleterious for genome stability and cell survival. However, the detailed mechanism on the response and repair of the replication stress-induced DNA damage during hematopoietic progenitor expansion remains elusive. Here we report that a novel zebrafish mutantcas003 with nonsense mutation in **topbp1** gene encoding topoisomerase II β binding protein 1 (**TopBP1**) exhibits severe definitive hematopoiesis failure. Homozygous topbp1cas003 mutants manifest reduced number of HSPCs during definitive hematopoietic cell expansion, without affecting the formation and migration of HSPCs. Moreover, HSPCs in the caudal hematopoietic tissue (an equivalent of the fetal liver in mammals) in topbp1cas003 mutant embryos are more sensitive to hydroxyurea (HU) treatment. Mechanistically, subcellular mislocalization of TopBP1cas003 protein results in ATR/Chk1 activation failure and DNA damage accumulation in HSPCs, and eventually induces the p53-dependent apoptosis of HSPCs. Collectively, this study demonstrates a novel and vital role of **TopBP1** in the maintenance of HSPCs genome integrity and survival during hematopoietic progenitor expansion.

Z648 Structural basis of endothelial Adgra2/Reck complex activity during Wnt7-dependent brain angiogenesis and blood-brain barrier formation in zebrafish. *N. Bostaille*, B. Vanhollebeke. Neurovascular Signaling Laboratory, ULB Neuroscience Institute, Université Libre de Bruxelles, Brussels, Belgium.

Distinct Wnt/β-catenin signaling cascades operate within endothelial cells (ECs) to control central nervous system vascular invasion and blood-brain barrier formation. In the mouse forebrain and zebrafish brain, Wnt7 ligands prime perineural ECs for invasion. In order to recognize these ligands, and hence to be competent for brain invasion, endothelial cells assemble unique receptor complexes at the plasma membrane that, in addition to classical receptor components like Fzd/Lrp, contain Adgra2 (previously known as Gpr124), an orphan member of the adhesion class of G protein-coupled receptors and Reck, a GPI-anchored glycoprotein. Adgra2 and Reck physically interact to assemble a potent synergistic Wnt7-specific co-activator complex that controls tip cell function during brain vascularization. How the partners interact and whether Adgra2 transmits a signal inside the receiving EC remains to be determined. In light of their function as key brain angiogenic regulators, determining the molecular modalities of Adgra2/Reck activity is of both clinical and fundamental importance. Adhesion class G protein-coupled receptors (aGPCRs) form the second largest class of GPCRs that context-dependently function as adhesion molecules, signal transducing GPCRs, or both concurrently. Adgra2 is a typical aGPCR characterized by a long extracellular domain containing multiple protein adhesion motifs, followed by a membrane-proximal GPCR-autoproteolysis autoinduced (GAIN) domain, seven membrane-spanning domains and a C-terminal intracellular domain. Through a combination of mutagenesis and *in vivo* brain angiogenic assays, we have molecularly dissected the Adgra2 protein motifs and determined their contribution to protein trafficking, interaction with Reck and angiogenic function. These analyses reveal key determinants of Adgra2/Reck function, uncover a novel mode of action for adhesion GPCRs and provide insights into the pharmacological potential of the Adgra2/Reck complex in cerebrovascular disorders.

Z649 Microtubule-actin crosslinking factor (Macf1) Function in Oocyte Polarity and Nuclear Positioning. *M. Escobar-Aguirre*, H. Zhang, R. Fuentes, A. Jamieson-Lucy, M. C. Mullins. University of Pennsylvania, Cell and Developmental Biology, Philadelphia, PA.

Cell polarity allows cells to regionalize their intracellular environment to perform a variety of specialized functions. In most vertebrates, polarity of the egg defines the anterior-posterior and dorsal-ventral axes of the embryo. Egg animal-vegetal (AV) polarity is derived from oocyte polarity, which is established early in oogenesis . AV polarity is established through the formation, translocation and disassembly of the Balbiani Body (Bb) at the vegetal pole. The Bb is conserved from insects to humans and is composed of organelles, RNAs and proteins. The Bb components, which include germ cell determinants, anchor to the vegetal cortex upon Bb disassembly in late stage I oocytes. Our lab discovered in zebrafish the only genes known to function in AV polarity formation in vertebrates: *bucky ball* and *macf1*. While Bucky ball is required for Bb formation, Macf1 is crucial for its disassembly. Macf1 is a conserved multi-domain cytoskeletal linker protein that can interact with microtubules (MTs), actin filaments (AF) and intermediate filaments (IF). Zebrafish *macf1* mutant oocytes display an: 1) enlarged Bb, 2)

acentric nucleus, and 3) a failure of Bb disassembly. Our aim is to elucidate the Macf1 dependent cytoskeletal linking mechanism that regulates AV polarity. First, we determined that Macf1 protein localizes perinuclearly, to the Bb, and upon Bb disassembly it distributes to the vegetal cortex. Second, we examined cytoskeleton function. Interestingly, disruption of AF phenocopies the *macf1* mutant phenotype. We found that cytokeratins (CK)- a type of intermediate filament- localize around the nucleus, are enriched in the Bb and exhibit a peripheral distribution in the cytoplasm in late stage I oocytes. These findings suggest that Macf1 Actin binding domain (ABD) and Plectin repeat domain (PRD) integrate cortical actin and CK to mediate Bb disassembly. To specifically test if the Macf1 actin binding domain (ABD) and Plectin repeat domain (PRD) function in Bb disassembly and nuclear positioning, we deleted the exons encoding these domains from the *macf1* endogenous locus by using Crispr/Cas9 technology. We found that Macf1Del-ABD mutant oocytes display the *macf1* null mutant phenotype whereby the nucleus is acentric and the Bb fails to disassemble. Importantly, Macf1Del-ABD protein is localized to the Bb like in wt. Surprisingly, deleting the PRD domain (Macf1Del-PRD) does not affect Bb disassembly or nuclear positioning. In summary, we determined that Macf1 functions via its ABD and actin filaments to mediate Bb disassembly and nuclear positioning, while the PRD is dispensable. To our knowledge, this is the first study to use genome editing to unravel the module-dependent function of a cytoskeletal linker in the context of cell polarity establishment.

Z650 Actr10, a component of the dynactin complex, regulates retrograde mitochondrial transport in axons. *C. Drerup*, A. Nechiporuk. Oregon Health & Science University, Portland, OR.

Mitochondrial transport in axons is imperative to mitochondrial health as well as the formation, stability and function of neural circuits. How mitochondria attach uniquely to the motor protein complexes necessary for their unidirectional movement is largely unknown. Using forward genetics, *in vivo* transport analyses, and biochemistry, we identified Actr10, a member of the dynactin complex, as a critical regulator of mitochondrial retrograde transport. Loss of Actr10 leads to mitochondrial accumulation in axon terminals due to failed attachment of this organelle to the dynein-dynactin complex. Anterograde mitochondrial transport and the localization and transport of dynein and other cargos in *actr10* mutants is unaffected. Biochemical and genetic interaction studies revealed the dynamin-like protein Drp1 as a partner for Actr10 in the retrograde transport of mitochondria in axons. Together, this work identifies Actr10 as the first specific regulator of mitochondrial attachment to the retrograde motor complex and enhances our understanding of the intricate cellular mechanisms required for the proper localization of this organelle in axons.

Z651 Apoptotic cartilage remodelng requires Kinesin I. *A. Santos*, P. D. Campbell, M. Gronska, F. L. Marlow. Albert Einstein College of Medicine, Bronx, NY.

Intramembranous ossification (bone formation within connective tissue), endochondral ossification (bone formation via mineralization and reabsorption of cartilage anlagen) and apoptotic remodeling of unmineralized cartilage (chondroptosis) are mechanisms underlying skeletal tissue morphogenesis. Chondroptosis, a chondrocyte specific form of apoptosis, is important for cartilage morphogenesis and is altered in some diseases, such as osteoarthritis. Nevertheless, the molecular basis remains elusive because chondrocytes undergo classical apoptosis in culture and *in vivo* models are lacking.

Here we describe a conserved role for the motor protein Kinesin I, *kif5B*, in maintaining muscle fiber integrity, and a novel role in apoptosis-mediated remodeling of cartilage. In addition to the hallmark features of chondroptosis (expansion of rER and Golgi, increased autophagocytic vacuoles, and patchy chromatin), extrusion and engulfment of mutant chondrocytes by neighboring cells occurs in *kif5B* loss of function (*kif5Blof*) mutants and chimeric contexts. Genetic interactions with Wnt planar cell polarity (PCP) mutants indicate distinct roles for PCP and *kif5B* in cartilage morphogenesis. Initial establishment of the cartilage is unaffected as early chondrocytic markers (*sox9* and *col2α1*) are properly expressed. Later, between 60 and 72hpf, when cartilage remodeling occurs, *kif5Blof* mutants undergo prolonged chondroptosis. Chimeric analyses, using cell transplantation, indicate a cell-autonomous requirement for Kif5B in regulating secretion, nuclear position, cell elongation and survival. Surprisingly, in these assays large groups of wild-type cells could support elongation of neighboring mutant cells. Mosaic expression of *kif5Ba* but not *kif5Aa,* in cartilage using Gal4/UAS similarly rescues the chondroptosis phenotype.

Metalloproteinases are crucial for cartilage remodeling before mineralization, and the cartilage phenotypes of MT1-MMP mutant mice resemble those of *kif5Blof* zebrafish. Moreover, Kif5B mediates membrane localization of MT1-MMP in other contexts; therfore, Kif5B may promote MT1-MMP functions in cartilage remodeling. To circumvent the earlier phenotypes reported for MT1-MMPa knockdown in zebrafish we utilized a pharmacological approach. However, general inhibition of metalloproteinase activity (EDTA) or more specific inhibition of MMP activity (GM6001) has failed to phenocopy *kif5Blof* mutants, and thus MT1-MMP contribution remains ambiguous. Cumulatively, our study reveals an essential role for Kif5B in cell polarization, secretion, and chondroptosis. *kif5Blof* mutants provide a new *in vivo* model to study a poorly understood form of programmed cell death that contributes to cartilage remodeling and osteochondrodysplasia in humans.

Z652 Protocadherin18a organizes notochord formation by regulating E-cadherin-mediated cell migration. *B. Bösze*[1], K. Stricker[1], S. Weber[1], V. Gourain[1], T. Thumberger[2], J. Wittbrodt[2], U. Strähle[1], S. Scholpp[1]. 1) Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, DE; 2) Centre for Organismal Studies, Heidelberg, DE.

Collective cell migration is a fundamental process required for tissue development, wound repair and cancer invasion. Gastrulation, the formation of the three germ layers is characterized by collectively migrating cells that anteriorly form the prechordal plate and posteriorly shape the notochord, the major skeletal element of the developing embryo. The cellular process leading to the formation of the rod-shaped notochord during collective cell migration of the mesodermal plate is unknown.

We found Protocadherin18a (Pcdh18a), a member of the cadherin superfamily as a novel regulator of cohesive cell migration during zebrafish

gastrulation. We show that Pcdh18a is expressed in the notochord tip cells (NTCs) and controls the adhesive and migratory behavior of this cell group. Enhanced adhesiveness and fast migration of the NTCs are required for formation of the 3D structure of the posteriorly-located notochord. Migrating cells rapidly adhere and de-adhere in order to translocate over their substrate. We indeed find that Pcdh18a regulates endocytosis of the E-cad/Fzd7 adhesion complexes in E-cad positive mouse fibroblasts, in human cervical cancer cells and during zebrafish gastrulation. Consistently, endocytic blockade in Pcdh18a positive cells reduces cell migration *in vitro* and *in vivo*. In summary, we conclude that during gastrulation, Pcdh18a positive NTCs organize the shape of the notochord, independently of cell migration events in the lateral plate mesoderm.

Z653 RGMa/Neogenin signaling promotes neural convergence by enhancing cell polarity and organizing microtubules. *Sharlene P. Brown*, Pradeepa Jayachandran, Valerie Olmo, Rebecca MacFarland, Rachel Brewster. UMBC, Baltimore, MD.

Neural convergence (NC) is the evolutionary conserved mechanism that narrows the neural plate (NP) enabling neural tube (NT) closure. Failure of this critical developmental process contributes to neural tube defects (NTDs), which occur in 1/1000 live births. Among the many candidate genes identified in model organisms that mediate NC, only those implicated in the planar cell polarity (PCP) pathway have so far been implicated in the etiology of human NTDs.

This study investigates the role of the Repulsive Guidance Molecule A (RGMa) and Neogenin signaling as regulators of NC in the zebrafish NP. RGMa is chemorepulsive to emerging retinal ganglion cell axons and prohibitive to the regeneration of damaged nerves. However, evidence from mouse, frog, and zebrafish suggest that RGMa/Neogenin signaling is required for NT formation. Although this latter function is poorly understood, the Cooper lab determined that RGMa signaling directly affected NT closure, the latest stage of tube formation. Absent from the literature is an understanding of the role of RGMa/Neogenin signaling in the earliest, most conserved stage of anterior NT development, NC, without which adequate NT closure is improbable due increased NP tissue width. We found that insufficient ligand or receptor similarly disrupted NC. While control embryos underwent adequate NP narrowing, RGMa and Neogenin-deficient embryos had widened NPs at the same somitic stage. To determine the cellular behaviors contributing to this NC defect, we examined movies of hindbrain NP cells in vivo from control and loss-of-function (LOF) embryos. Our quantitative data show that control embryos extend membranous protrusions toward the midline and lateral surface of the tissue. However, both RGMa and Neogenin LOF randomized the protrusiveness of NP cell membranes. Cells deficient in this pathway were also rounded instead of polarized perpendicular to the midline. The lack of polarization in these embryos is reminiscent of defects observed when microtubule (MT) stability/organization is disrupted. Therefore, we investigated the requirement of RGMa and Neogenin for effective MT organization. As we have reported previously, NC in the zebrafish involves rearrangement of the MT cytoskeleton into a progressively linear array perpendicular or oblique to the midline. In this study, control NP cells were found to have archetypical MT organization. However, RGMa and Neogenin LOF severely shortened the length of MT arrays. These observations suggest that MTs may be downstream targets of RGMa/Neogenin signaling to promote convergence of the NP and thus proper NT formation. Ongoing work investigates the connection between RGMa/Neogenin and cadherin-based cell adhesion to mediate cell behavior essential to NC. .

Z654 Hippo signaling regulates ventricle morphogenesis via Taz-dependent activation of Wnt and Notch signaling. *L. G. Selland*, A. J. Waskiewicz. University of Alberta, Edmonton, Alberta, CA.

Specialized boundaries form between the rhombomeres in the hindbrain and provide signaling cues to the surrounding tissues. We are investigating the role of rhombomere boundaries in the morphogenesis of the hindbrain ventricle in zebrafish. The ventricular system forms a specialized neural circulatory system and aberrant ventricle development correlates with hydrocephalus and neurodevelopmental disorders such as schizophrenia and autism. Initial patterning of the neural tube enables the correct positioning of the ventricles. Characteristic morphogenesis and cell proliferation then shapes the ventricles, while the initial secretion of embryonic cerebrospinal fluid inflates the ventricles. The Grinblat and Wilkinson laboratories have provided evidence that Zic1 and Zic4 from the roof plate activate Notch signaling via *rfng,* which subsequently drives Wnt signaling at rhombomere boundaries. Our research goal is to identify novel signaling pathways that regulate hindbrain ventricle formation. By screening for pathway components with the correct spatio-temporal expression, we determined that the Hippo signaling pathway transcriptional co-activator *taz,* is expressed in the hindbrain roof plate. Using TALEN mutagenesis, we created mutants with a 29 bp deletion, resulting in a loss of all functional domains of the Taz protein. *Taz*$^{-/-}$ mutants display midline separation defects in the hindbrain ventricle. This phenotype is apparent by 22hpf and persists through 36hpf indicating defects in the initial shaping of the brain and ventricle inflation. Examination of genes identified by the Sive lab to be required for ventricle morphogenesis (*ppp1r12a, mpp5a* and *crb2a*) showed no alterations in expression. Therefore, we hypothesized that *taz* may regulate rhombomere boundary signals independent of other known roof plate derived cues in order to drive ventricle morphogenesis. Examination of roof plate signals, including the *zic* family of genes, revealed no alterations in expression, however *taz*$^{-/-}$ mutants fail to express both *wnt1* and *rfng* at rhombomere boundaries. Treatment with a pharmacological inhibitor of Wnt signaling (XAV939) results in defective ventricle morphogenesis. To determine if *rfng* is responsible for the expression of *wnt1* at rhombomere boundaries, we used a pharmacological inhibitor of Notch signaling (DAPT) and assayed for *wnt1* expression. DAPT treatment did not affect *wnt1* expression at rhombomere boundaries, although it did perturb ventricle morphogenesis. This is the first evidence of Hippo signaling involvement in ventricle development, and supports a model in which Taz-dependent activation of Wnt and Notch signaling pathways at rhombomere boundaries regulates hindbrain ventricle formation.

Z655 The Joubert syndrome protein INPP5E controls ciliogenesis by regulating phosphoinositides at the apical memebrane. *Y. Cao*, W. Xu, M. Jin, R. Hu, F. Zhang, H. Wang. Tongji University, Shanghai, Shanghai, CN.

Phosphoinositides, a family of phosphorylated derivatives of phosphatidylinositol (PtdIns), are tightly regulated both temporally and spatially by PtdIns phosphatases and kinases. Mutations in *Inositol polyphosphate 5-phosphatase E* (*INPP5E*) cause Joubert syndrome, a human disorder associated with numerous ciliopathic defects including renal cyst formation, linking phosphoinositides to ciliopathies. However, the molecular mechanism by which INPP5E-mediated phosphatidylinositol signaling regulates ciliogenesis and cystogenesis is unclear. Here, we utilize an *in vivo* vertebrate model of renal cystogenesis to show that Inpp5e functions in both by hydrolyzing PtdIns(3,4,5)P3 and stabilizing PtdIns(4,5)P2 at the apical membrane, which in turn directs apical docking of basal bodies in renal epithelia. Knockdown or knockout of *inpp5e* leads to ciliogenesis defects and cystic kidney in zebrafish. Furthermore, knockdown of *inpp5e* in embryos leads to defects in cell polarity, cortical organization of F-actin, apical docking of basal bodies, and apical segregation of PtdIns(4,5)P2 and PtdIns(3,4,5)P3. Knockdown of *ezrin*, which encodes an ERM (Ezrin, Radixin and Moesin) protein that crosslinks PtdIns(4,5)P2 and F-actin, phenocopied *inpp5e* knockdowns. Strikingly, overexpression of *ezrin* rescued *inpp5e* morphants, suggesting that *ezrin* functions downstream of *inpp5e*. Finally, treatment with the PtdIns(3,4,5)P3 inhibitor, LY294002, rescues the cellular, phenotypic and renal function defects in *inpp5e* knockdown embryos. Together our data indicate that Inpp5e is a key regulator of cell polarity in the renal epithelia by inhibiting PtdIns(3,4,5)P3 and subsequently recruiting PtdIns(4,5)P2, Ezrin, F-actin and basal bodies to the apical membrane, and suggest a possible novel approach for treating human ciliopathies.

Z656 An unexpected influence of the extracellular matrix on cilia function in zebrafish. *E. K. LeMosy*, H. Neiswender, S. Navarre, D. J. Kozlowski. Augusta Univ., Augusta, GA.

Tinagl1 is a basement membrane protein conserved across animal species having three germ layers; mammals have an additional family member, Tinag. Genetic studies by others in fly and mouse models have not yielded a clear *in vivo* requirement for Tinagl1. Principally using MO knockdown in zebrafish, we observed defects consistent with a 'ciliopathy' spectrum, including small eye, body curvature, L/R randomization of heart looping, hydrocephalus, renal cysts, and craniofacial defects. New results with transient Crispr/Cas9 mosaic knockout and an ENU truncation mutant support heart looping, renal, and craniofacial defects, and mutant analysis is our current focus. With the MOs, we documented shorter and fewer cilia in Kupffer's vesicle and pronephric duct. Tinagl1 morphant pronephros and craniofacial defects were enhanced by co-injection with a Wnt MO but not control MO, and partially rescued by *tinagl1* mRNA; *ctnnb2* but not *egfp* mRNA was also demonstrated to partially rescue the pronephric cilia defect. These results are consistent with a Nusse lab demonstration that fruitfly Tinagl1 binds to Wg and is required for its function at a distance from secreting cells *in vitro*. Overall, our results support a hypothesis that, in zebrafish, Tinagl1 is broadly required for cilia function and may act via Wnt/beta-catenin signaling shown by others to function upstream of the motile cilia regulator *foxj1a* in pronephros and KV. We plan to test whether Tinagl1 can be linked to cilia regulation in mammalian cells, and whether it physically interacts with zebrafish Wnt(s) and activates downstream target genes or regulates PCP components in either model. Zebrafish may be a particularly favorable model for studying Tinagl1: it has only the *tinagl1* gene, so compensatory expression of Tinag is removed as an issue, yet it has good conservation of the organ systems in which Tinagl1 is highly expressed in mammals. In contrast, flies express modified cilia only in sperm and sensory neurons, and have more divergent organs, offering less scope for comparative studies and detection of context-specific effects. Interestingly, a zebrafish laminin mutant is reported to show short KV cilia able to initially establish L/R pattern, but later signal diffusion across the midline results in L/R randomization of abdominal organs. Mechanisms for basement membrane Tinagl1 and laminin roles in cilia regulation may involve signaling at focal adhesions in addition to promoting signaling of growth factors such as Wnts.

Z657 A High-Throughput workflow for CRISPR/Cas9 mediated targeted mutagenesis to model human disease genes in zebrafish . *Gaurav Varshney*[1], Wuhong Pei[1], Blake Carrington[1], Kevin Bishop[1], Erin Jimenez[1], Johan Ledin[2], Raman Sood[1], Shawn Burgess[1]. 1) National Human Genome Research Institute, NIH, Bethesda, MD; 2) Uppsala University, Uppsala, Sweden.

Advances in sequencing technologies have enabled the rapid identification of human disease genes by GWAS or whole exome sequencing techniques. There is a large-gap between identification of human disease genes and their functional validation. Numerous publications have demonstrated the efficacy of gene targeting in zebrafish using CRISPR/Cas9 including a variety of tools and methods for guide RNA synthesis and mutant identification. While all the published techniques work, not all approaches are readily scalable to increase throughput. In addition, zebrafish have been shown to effectively recapitulate disease phenotypes, however models that fail to generate relevant phenotypes are rarely reported. We recently described a CRISPR/Cas9 based high-throughput mutagenesis and phenotyping pipeline in zebrafish. Here we present a complete workflow including target selection, cloning-free single guide RNA (sgRNA) synthesis, microinjection, validation of the target-specific activity of the sgRNAs, founder screening to identify germline transmitting mutations, determination of the exact lesion by PCR and next generation sequencing (including software for analysis), and genotyping in the F_1 or subsequent generations. We used this high throughput pipeline to target all published human genes linked to non-syndromic deafness in zebrafish. We will present phenotyping data from homozygous mutants, and determine a rate of successful modeling in zebrafish.

Z658 Resource Construction at the China Zebrafish Resource Center. *Y. Sun*, L. Pan, K. Li, F. Xiong, X. Xie, Y. Zhang. China Zebrafish Resource Center, Institute of Hydrobiology, CAS, Wuhan, China.

In China, zebrafish was adopted in lab research in early 1990s, and the zebrafish research community has been rapidly growing since 2000. To meet the growing needs of zebrafish strains and technical support, in October 2012, the China Zebrafish Resource Center (CZRC, website: http://zfish.cn) was established at the Institute of Hydrobiology (IHB), Chinese Academy of Sciences (CAS) in Wuhan. After three years'

development, CZRC has maintained more than 1000 mutant and transgenic zebrafish lines, and a number of DNA plasmids and cell lines tillnow. All the fish lines provided by CZRC are tightly linked to the web information of Zebrafish Information Network (ZFIN). In addition to providing the regular fish resources, CZRC also provides transgenic service, knock-out service and technical training. In 2013, 40 labs in China started the Zebrafish All Gene Knock-out Project (ZKO Project) for Chromosome 1. The final goal of ZKO project is to knock-out all the 1333 genes on zebrafish chromosome 1 using CRISPR/Cas9 technology. Up to now, more than 900 genes have been successfully knocked out. CZRC is the project coordinator, and all mutant lines built in the project will be verified and preserved by CZRC and published as open resources to the whole research field. With the progress of ZKO project, CZRC will expand its fish stocks to 2000 lines by the end of 2016, and it is becoming one of the major resource centers in the global zebrafish community.

Z659 Phenome-scale screen defines post-embryonic gene function during the zebrafish larval-to-adult transition. *R. Fuentes*[1], A. Kugath[1], C. Nwaezeapu[1], G. Hu[1], T. Cooper[2], J. Fried[2], C. Scahill[4], J. Copper[2], K. Helde[3], C. Moens[3], K. Cheng[2], E. Busch-Nentwich[4], D. Stemple[4], S. Fisher[1], M. Mullins[1]. 1) University of Pennsylvania, Philadelphia, PA; 2) Penn State College of Medicine, Hershey, PA USA; 3) Fred Hutchinson Cancer Research Center, WA, USA; 4) Wellcome Trust Sanger Institute, Cambridge, UK.

With the dawn of the post-genomic era and the impact of the genomic revolution, knowledge of most of the encoded genes and their molecular nature has been revealed. However, knowledge of the *in vivo* functions for most of the genes remains incomplete. Thus, the study of phenotypes, or phenomics, has emerged as a genome-wide discipline to link gene sequence and function. Zebrafish has become an attractive and accessible vertebrate model system for phenomics, providing new insights into genotype-phenotype relationships and for modeling human disease. The Sanger Center has developed a high-throughput mutation identification approach to generate a large set of molecularly-defined mutant genes in the zebrafish. It has focused its phenotypic analysis on the embryonic to early larval period and has found that most null mutant alleles do not exhibit an apparent function during these early developmental stages. We have established a new phenotyping screen strategy to identify genes regulating later developmental periods and that act in the adult, as well as to identify human disease genes that typically manifest in the adult. We have analyzed more than 500 molecularly-defined gene knockouts in the zebrafish during late larval to adult stages. We have isolated numerous factors regulating post-embryonic stages, including male sterile, maternal-effect, late larval lethal and adult morphology genes, corresponding to several human disease genes. Our screen serves as the first step towards gaining mechanistic insights into the general structure of complex traits during post-embryonic developmental stages in vertebrates. Importantly, it will contribute to determining the zebrafish phenome during late larval, juvenile, and adult stages, including a collection of traits dispensable for reproduction, survival and body formation. Our studies provide a resource of phenomics data for future in-depth analysis of gene function by the scientific community.

Z660 Precise editing of the zebrafish genome by homologous recombination made simple and efficient. *K. Hoshijima*, M. Jurynec, D. Grunwald. University of Utah, Salt Lake City, UT.

Studies in zebrafish have made substantial contributions to our understanding of gene function in vertebrates. Large-scale genetic screens have led to discoveries of components and pathways underlying essential biological processes. More recently the imprecise repair of targeted DSBs induced by programmable nucleases has expanded use of the zebrafish further by providing a means for creating loss of function mutations affecting selected genes of interest. Importantly, the DSB lesions induced by the programmable nucleases stimulate both repair and recombination pathways, dramatically increasing the chance of integrating donor DNA sequences at the targeted locus. Indeed, a handful of reports have described successful integration of donor sequences at the targeted locus in zebrafish using different molecular configurations, *i.e.*, single-stranded oligodeoxynucleotides or double-stranded DNA (dsDNA), with or without homologous arms.

We have focused on sequence replacement or integration via homologous recombination between the host genome and exogenously supplied dsDNA as donor molecules. We found that digestion of donor ends with I-SceI enzyme in defined orientation enhances homologous recombination efficiency in zebrafish embryos. Under these conditions, several kilobase long stretches of sequence can be replaced efficiently. We used this approach to accomplish a variety of precise editing events, including: a single base substitution, in-frame integration of sequences encoding an epitope tag, and in-frame integration of reporter sequences accompanied by disruption of the targeted host gene. Taking advantage of the ability to integrate long donor dsDNA molecules, we also developed a method for efficiently isolating silent genome modifications, by incorporating a linked reporter within the donor sequences. Presence of the linked reporter, which can be excised subsequently by FLP/FRT-mediated recombination, makes it easy to recover and identify edited alleles. With these improvements, we created a conditional mutant in zebrafish in which a pair of loxP sequences flanked a target exon. The floxed allele maintains wild-type function but can be converted to a null mutation in the presence of Cre protein. Thus, genome editing mediated by programmable nucleases continues to advance our ability to perform genetic analysis in zebrafish.

C. elegans DEVELOPMENT, CELL BIOLOGY AND GENE EXPRESSION MEETING

Poster Session Abstracts

W4001A Unearthing Aneuploidy: A Study of the Influence of Double Strand Breaks on Oocytes in *Caenorhabditis elegans*. *F. Balmir*, J. Yanowitz. Magee Womens Research Institute, Pittsburgh, PA.

Chromosomal abnormalities in oocytes are a leading cause of miscarriage and genetic disorders of the fetus. A major underlying cause of these abnormalities is defects in meiotic crossover (CO) formation. To achieve COs, the topoisomerase-like enzyme, SPO-11, creates DNA double strand breaks (DSBs), allowing for repair of those breaks by homologous recombination. COs can be seen as chiasmata that help to correctly orient chromosomes on the spindle during metaphase I for proper segregation. Therefore, without DSBs and subsequent CO events, chromosomes risk missegregation. By understanding the components of DSB formation, we gain insight into events in recombination and the creation of COs with their associated chiasmata. Nevertheless, our understanding of the protein complexes that regulate DSB formation is lacking. *Caenorhabditis elegans* is ideal for the study of meiosis, DSBs, and aneuploidy given its ease of genetic manipulation and shared meiotic characteristics with women. By analyzing double mutants of genes involved in DSBs, we can build networks of the genetic interactions required for DSB formation. We have analyzed a matrix of interactions between partial loss-of-function alleles of genes involved in DSB formation in C. elegans. These include mutations in *lin-35, cep-1, dsb-2, rec-1, him-17, him-5, parg-1,* and *mre-11.* We then analyzed diakinesis oocytes by whole mount staining followed by confocal microscopy and 3D visualization. Assessment of achiasmate chromosomes has allowed us to determine synthetic interactions for CO formation in these sets of mutants. We also analyzed the effects of the mutations on brood size and frequency of males. Preliminary analysis suggests that the DSB genes fall into multiple groups that interact synergistically to impact break formation.

W4002B New complexities in ATM/ATR regulation in meiosis. *W. Li*[1,2], J. Yanowitz[2]. 1) School of Medicine of Tsinghua University, Beijing, China; 2) Magee-Womens Research Institute, University of Pittsburgh School of Medicine, Pittsburgh, PA.

Ataxia-telangiectasia mutated (ATM) and RAD3-related (ATR) are key players in the mitotic DNA damage response (DDR) functioning to both recognize double-strand breaks (DSBs) and signal their presence to the cell. ATM and ATR have also more recently been shown to have a role in meiosis where they can influence the number of programmed DSBs that are made by the topoisomerase-like enzyme Spo11. In yeast and mammals, ATM acts as a negative regulator of Spo11-dependent DSB formation. By contrast, yeast ATR appears to function in a positive feedback loop for the formation of DSBs. We are interested in understanding how ATM and ATR work antagonistically to achieve a balance of meiotic DSBs. Efforts to further elucidate the *in vivo* roles of ATM and ATR in meiosis in mammals have been hampered by the fact that *atm-1* mutant mice are infertile, deficient in making mature gametes. Therefore we exploit the facile genetics and superb cytological of the nematode, *C. elegans* to probe the function of these genes in meiotic.

I have been investigating the roles of *C. elegans* ATM and ATR orthologs, ATM-1 and ATL-1, respectively, by analyzing the phenotypic consequences of *atm-1* and *atl-1* mutations and double mutants with components of the DSB machinery. I have been analyzing the effects of these mutations on COs formation through analysis of diakinesis-stage oocytes when chromosomes with COs condense into bivalent, cruciform structures. I also monitor how many DSBs are channeled into homologous recombination by assaying recruitment of RAD-51 to the chromatin by immunolocalization.

In my studies to date, we have found the surprising result that while *atm-1* mutants produce more DSBs during meiosis, as in other systems, fewer crossovers (COs) are formed. This finding suggests that ATM-1 not only regulates DSB formation but also influences downstream processing of these breaks. Two exciting possibilities are being explored: *atm-1* could modulate repair pathway choice, directing DSBs to CO outcomes; alternatively *atm-1* may function in a crossover checkpoint, preventing apoptosis if the correct level of DSBs is achieved. Further study will focus on determining the functions of *atm-1* and *atl-1* in formation of DSBs and their downstream processing.

W4003C NuRD Chromatin Remodelers Block Checkpoint Activation in the *C. elegans* Germ Line. *Sol Sloat*, Julia Rigothi, Carolyn Turcotte, Nicolas Andrews, Paula Checchi. Marist College, Poughkeepsie, MY.

In order to form viable gametes, double stranded breaks (DSBs) must be induced and correctly repaired during meiotic prophase I. Failure to correctly repair DSBs can result in defective gametes, which in humans, results in infertility, miscarriage, or chromosome disorders. We have found that in *C. elegans*, timely DSB repair is mediated by the Nucleosome Remodeling Deacetylase (NuRD) complex. Mutations in the genes encoding Chromodomain helicase DNA binding protein CHD-3 and its paralog LET-418 result in persisting DSBs and chromosome fragmentation that are coincident with increased germline apoptosis. Here, we investigate the genetic, cellular and molecular role of the NuRD chromatin remodeling complex and its relationship with meiotic checkpoint signaling in the *C. elegans* germ line. As in other organisms, checkpoint kinase 1 (CHK-1) is responsible for coordination of the DNA damage response (DDR) that leads to either cell cycle arrest, DNA repair, or apoptosis. We found that *let-418* mutants had higher levels of phosphorylated CHK-1 protein (pCHK-1) than wild type controls. These data are corroborated by cellular evidence in which pCHK-1 foci are detected in *let-418* germ cells using antibody staining, as well as genetic evidence demonstrating that knockdown of *chk-1* as well as its downstream effector *cep-1*(p53) suppress apoptosis in *let-418* mutants. Taken together, these results support a model wherein the NuRD complex machinery ensures error-free gamete formation by inhibiting meiotic checkpoints.

W4004A NuRD paralogs CHD-3/LET-418 promote meiotic double-stranded break repair In *C. elegans* . *Carolyn Turcotte*, Julia Rigothi, Erika Rosenkranse, Paula Checchi. Marist College, Poughkeepsie, NY.

Normal meiotic progression requires that programmed double stranded breaks (DSBs) are induced on all chromosomes. This is significant, as unrepaired DSBs lead to defective gametes, which manifest in severe problems such as miscarriages and chromosomal disorders such as Down syndrome. Accordingly, DSBs must be faithfully repaired. This is accomplished by a series of conserved mechanisms which include ATP-dependent chromatin modifiers, proteins that epigenetically alter DNA. We have demonstrated a role for the nucleosome remodeling (NuRD) complex in DSB repair, wherein the Chromodomain helicase DNA binding protein CHD-3 and its paralog LET-418 promote normal meiotic

progression and DSB repair in *C. elegans*. Loss of *chd-3* alone results in a significantly decreased brood size, and these defects are exacerbated when combined with a loss-of-function *let-418* allele. We discovered that the disruption of both paralogs also leads to chromosome fragmentation, which is indicative of faulty repair mechanisms. Using an antibody against the DSB marker RAD-51, we also found that DSBs abnormally persist in meiotic nuclei of *let-418* mutant germ lines. We are currently generating several strains which will help us to further understand the molecular nature of these defects. Taken together, these experiments will enable us to determine the role of the NuRD complex in the systematic repair of DSBs, which can be applied to other organisms such as humans.

W4005B SMRC-1, a putative annealing helicase, links chromatin regulation and DNA repair in the *C. elegans* germ line. *Bing Yang*, Xia Xu, Eleanor Maine. Syracuse University, Syracuse, NY.

Histones can receive many different modifications, and the presence/absence of certain modifications is implicated in transcriptional control and chromosomal events. One modification, histone H3 lysine 9 dimethylation (H3K9me2), is associated with unsynapsed chromatin during meiosis in many organisms, including *C. elegans* [1-3]. For example, in the male *C. elegans* germ line, the single X chromosome does not synapse and, during pachytene, is detected as a strong focus of H3K9me2 by immuno-labeling. In contrast, a much lower level of H3K9me2 staining is detected on synapsed autosomes. This interesting phenomenon led to the question of how H3K9me2 marks are specifically targeted to their genomic sites.

In order to address this question, we are identifying H3K9me2 methyltransferase (MET-2) interactors. To do so, we generated epitope-tagged *met-2* transgenes and antibody against MET-2. Using these reagents, we performed immunoprecipitation and tandem mass spec analysis to recover potential interactors. One candidate protein that we recovered is the *smrc-1* (C16A3.1) gene product. SMRC-1 is the *C. elegans* ortholog of mammalian SMARCAL1 (SWI/SNF-related matrix-associated actin-dependent regulator of chromatin subfamily A-like protein). Mammalian and *Drosophila* SMARCAL1 family members are annealing helicases that provide protection from DNA replication stress. Little is known about SMARCAL1 function in the germ line.

Using CRISPR-Cas9 methods, we generated *smrc-1* nonsense mutations and *flag*-tagged the endogenous *smrc-1* gene. We immunoprecipitated 3xFLAG::SMRC-1 and confirmed the interaction with MET-2. We evaluated 3xFLAG::SMRC-1 expression and observed that it localizes to mitotic and meiotic nuclei in both male and hermaphrodite germ lines. *smrc-1* nonsense mutations cause germline defects, including meiotic defects consistent with impaired recombination. Meiotic H3K9me2 is elevated and abnormally distributed in *smrc-1* males. *smrc-1* hermaphrodites exhibit maternal-effect embryonic lethality and, under conditions of temperature stress, exhibit a progressive reduction in brood size leading to complete infertility within several generations. We are investigating the relationships among SMRC-1 function, MET-2 function, and DNA repair.

W4006C Sex pheromones of *C. elegans* males potentiate the female reproductive system. *E. Zucker Aprison*, I. Ruvinsky. University of Chicago, Chicago, IL.

The *Caenorhabditis elegans* metabolome contains over a hundred ascaroside molecules. Most of them have no known function, or no function at all, but some act as pheromones. Two of these molecules, ascr#10 and ascr#3, are produced in different proportions by males and hermaphrodites. We report that when a hermaphrodite senses a male-specific mixture of these molecules, it changes several aspects of its reproductive physiology, including signaling that guides sperm toward oocytes. During evolution from an ancestor that had both males and females, *C. elegans* hermaphrodites lost several female-specific traits, but their reproductive system retained the ability to respond to male pheromones. This greatly aids them during recovery from heat stress. We suggest that serendipitous side benefits of female-specific traits could be a general cause of their retention during evolution.

W4007A Identifying a role for ETR-1 in *C. elegans* reproduction and germ line apoptosis. *Ruby Boateng*[1], Andy Golden[2], David Hall[3], Anna Allen[4]. 1) Howard University, Washington, DC; 2) NIDDK/NIH, Bethesda, MD; 3) Albert Einstein College of Medicine, Bronx, NY; 4) Howard University, Washington, DC.

In the *C. elegans* hermaphrodite germline, over half of the developing germ cells are eliminated through "physiological" germ cell apoptosis. This elimination is hypothesized to provide the surviving germ cells both the cytoplasmic nutrients and space required to undergo the growth necessitated to form a healthy, fertilization-competent oocyte. While this elimination involves the core apoptotic machinery of CED-9, CED-4 and CED-3, how this machinery is activated in "physiological" germ cell apoptosis remains unknown. Recently, we identified an unknown role for the ELAV-type RNA binding protein ETR-1 in germline apoptosis. This study aims to investigate the role of ETR-1 in both reproduction and "physiological" germ cell apoptosis.

ETR-1 is known to play a role in muscle development, as *etr-1(RNAi)* animals arrest at the two-fold stage of embryogenesis. Our fertility assays conducted in wild-type, a somatic defective RNAi mutant *(rrf-1(pk1417))* and a germline defective RNAi mutants *(ppw-1(pk1425))* implicate a reproductive role of ETR-1. *etr-1(RNAi)* animals have a reduced brood size compared to control animals in all three mutant lines tested. Additionally, the ability of ETR-1 depletion to suppress the published WEE-1.3-depletion infertility phenotype is dependent on ETR-1 being depleted in the soma. While investigating the cause of the reduced brood size of *etr-1(RNAi)* animals, we observed an increase in the number of germ cells undergoing apoptosis.

We utilized Transmission Electron Microscopy (TEM) to investigate the germlines of ETR-1-depleted animals. TEM confirms the increase in apoptotic germ cells and reveals significant defects in the structure of the somatic gonadal sheath cells encasing the germline compared to controls. Since the gonadal sheath cells are involved in the engulfment of apoptotic germ cells, and we had previously localized ETR-1 to the

sheath, this implies a defect in the engulfment of dying germ cells. We will demonstrate that ETR-1 depletion in *ced-1(e1735)* engulfment mutants rescues the *etr-1(RNAi)* reduced brood size, and co-depletion of *ced-1(RNAi)* and *etr-1(RNAi)* suppresses the increase in the number of apoptotic bodies observed in *etr-1(RNAi)* animals.

Combined this data reveals a novel role for ETR-1 in reproduction and "physiological" germ cell apoptosis, potentially in the process of engulfment. These studies will increase our understanding of the apoptotic pathway and how ETR-1, a highly conserved CELF/BRUNOL protein, influences an organism's reproductive capability.

W4008B Developmental consequences of the inappropriate transgenerational inheritance of histone methylation in *spr-5;met-2* mutant worms. *B. Carpenter*, D. Katz. Emory University, Atlanta, GA.

Reestablishing the epigenetic ground state of the *Caenorhabditis elegans* (*C. elegans*) zygote is required for normal development and ensures that information is transferred properly from one generation to the next. Two epigenetic enzymes, the H3K4me2 demethylase, SPR-5, and the H3K9 methyltransferase, MET-2, are maternally deposited into the oocyte and cooperate to reestablish the epigenetic ground state by modifying histone methylation. Progeny of worms lacking *spr-5* and *met-2* rapidly accumulate H3K4me2 resulting in somatic expression of spermatogenesis genes and sterility, while worms that lack both SPR-5 and MET-2 exhibit a maternal effect sterile phenotype. Compared to Wildtype, these double mutants display multiple developmental defects including, developmental delay, perturbed vulva formation, and defects in oogenesis. Despite this, the mechanisms by which SPR-5 and MET-2 transgenerationally regulate development is unclear. Here, we show that *spr-5;met-2* mutant worm progeny exhibit a severe L2 developmental delay in both the germline and soma. This phenotype hints that there could be feedback between germline and soma. In addition, we discuss experimental approaches to examine the mechanisms by which SPR-5 and MET-2 regulate cell fate decisions during *C. elegans* development.

W4009C SAMP-1 Regulates Chromosome Segregation in *C. elegans* Spermatogenesis. *A. J. Deshong*, A. Kuzmanov, J. Engebrecht. University of California Davis, Davis, CA.

Meiosis is the specialized form of cell division in which a single DNA replication event is followed by two successive rounds of chromosome segregation to produce haploid gametes. Errors in meiosis can cause aneuploidy, a major cause of both miscarriage and genetic developmental disorders in humans. The meiotic program must be differentially regulated between males and females to generate sperm and eggs. The highly conserved protein, SAMP-1, is required for regulating chromosome segregation during *C. elegans* spermatogenesis, but not oogenesis. *samp-1(tm2710)* mutant hermaphrodites show complete sterility. However, sterility of the *samp-1(tm2710)* mutants was rescued by providing wild-type sperm, suggesting the sterility phenotype is largely sperm-dependent. SAMP-1 is a 588 amino acid predicted transmembrane protein embedded in the inner nuclear membrane. By immunofluorescence, SAMP-1 is detected at the nuclear periphery in the germ lines of both males and hermaphrodites using an antibody generated against amino acids 338-555. Interestingly, SAMP-1 undergoes a dynamic shift in localization during male meiosis. At the end of prophase I in the male germ line, SAMP-1 begins to localize in the nucleoplasm and by metaphase I becomes concentrated on bivalent chromosomes at the interface between homologs. Preliminary evidence suggests that this change in localization is regulated by proteolytic cleavage. We are using CRISPR gene editing techniques to fluorescently tag SAMP-1 at the N-terminus, C-terminus, and an internal site to determine the mechanisms underlying dynamic localization in the male germ line. Lastly *samp-1(tm2710)* mutant males exhibit defects in meiotic spindle formation. To monitor these highly dynamic processes, we are using live-cell imaging to capture meiotic cell division in real time to characterize the dynamics of the defects that are observed in *samp-1(tm2710)* mutant males. *samp-1(tm2710)* mutant males show a hypomorphic phenotype during anaphase I of meiosis in which severe segregation defects are present in 66% of observed divisions. Defects include shortened metaphase spindles, multiple lagging chromosomes, delayed anaphase, and inappropriate centrosome separation. Interestingly, in the observed "normal" divisions in *samp-1(tm2710)* mutant males which lack the above defects, anaphase I occurred faster than in wild type. Severe anaphase defects suggest that SAMP-1 is playing a role in regulating cohesion release and/or kinetochore attachments.

W4010A Sex specific differences in *C. elegans* meiosis. *S. Fielder*, W. G. Kelly. Emory University, Atlanta, GA.

Meiotic synapsis is a conserved process that is required for proper segregation of homologous chromosomes in both oogenesis and spermatogenesis. In early prophase I, homolog sets are connected together by a bridge-like complex of synapsis proteins that keep them in close proximity to facilitate crossing over. If a chromosome is unable to pair and synapse, such as the lone X in *C. elegans* males, it is targeted for heterochromatin assembly in a process called meiotic silencing. This process has been observed in numerous organisms, including in mammals. I have observed in *C. elegans*, meiotic silencing, measured by histone H3 lysine 9 dimethylation accumulation (H3K9me2), occurs in both male and hermaphrodite mutants that are unable to pair and synapse one or two sets of homologs (e.g., *zim-2* mutants, which are unable to pair chromosome V). Consistent with this trend, male mutants that completely lack synapsis show accumulation of H3K9me2 on all chromosomes. However, this pattern is strikingly different in hermaphrodites that lack synapsis: they do not show any increased accumulation of H3K9me2. This indicates that there may be a previously undescribed checkpoint that recognizes a failure to initiate synapsis and bypasses meiotic silencing in hermaphrodites. The global H3K9me2 enrichment in males indicates that this proposed checkpoint is sex specific or regulated differently in males. Analysis of this sex specific difference will be presented.

W4011B Identification of Genes that Regulate the Activation of *C. elegans* Sperm. *A. Greer*, D. Chavez, T. Shimko, B. Philpot, A. Duffy, K. Mylroie, G. Stanfield. University of Utah, Salt Lake City, UT.

Nematode sperm become competent for motility and fertilization during a process termed sperm activation, which is regulated by specific extracellular signals in males and hermaphrodites. While hermaphrodites create their own sperm during their last larval stage and store it for

future use, adult males continually create sperm, which activate when the sperm is transferred to a hermaphrodite. Furthermore, hermaphrodites and male sperm activation pathways differ from each other. Hermaphrodite sperm activation requires the activity of a set of sperm genes termed the *spe-8* group, which mediate the response to extracellular zinc. The pathway by which male sperm become active involves a signaling pathway including *swm-1*, *try-5*, and *snf-10*. SWM-1 is a serine protease inhibitor. When it is absent, sperm is prematurely activated within the male gonad and is rarely transferred to hermaphrodites. TRY-5 is the next protein in the sperm activation cascade and is a seminal fluid serine protease. When TRY-5 is absent, males do not transfer activator, though they are still fertile due to activation by hermaphrodite signals. The protein SNF-10, an SLC6 transporter, is found in the plasma membrane of sperm and is required for activation of male sperm by TRY-5. To identify additional genes within the sperm activation cascade, the Swm-1 activated-sperm phenotype was used as the basis of a genetic suppressor screen.

Analysis of mutants from the *swm-1* suppressor screen suggests that many genes are involved in sperm activation. One goal of this project is to characterize the phenotype of suppressor mutants. First, we are using hermaphrodite brood counts to measure the fertility of each mutant. We find that multiple male pathway mutants have decreased fertility, unlike the previous characterized mutants in this class. We are also performing experiments to distinguish between potential roles in sperm vs. upstream of the TRY-5 protease. We are using in vitro activation assays to test if any of these genes functions in sperm or is needed for response to the protease signaling pathway. We are also examining the effect of these mutations on localization or transfer of TRY-5::GFP. A second current goal of this project is to identify two of these genes, which we have shown to represent two novel regulators in the male (*jn19*) and hermaphrodite (*jn15*) pathways. We mapped and sequenced these mutants. Prioritizing candidate genes according to preexisting data for sperm-enriched gene expression, we are using CRISPR to generate candidate gene deletions that may mimic the *jn19* and *jn15* phenotypes. These experiments will provide insight into protease signaling, which is important for cell motility as well as other processes.

W4012C Maternal diet influences intergenerational phenotypic plasticity affecting progeny size and starvation resistance. *Jonathan Hibshman*, Anthony Hung, Ryan Baugh. Duke University, Durham, NC.

Dietary restriction (DR) delays aging but reduces fertility. We demonstrate maternal effects of DR in the roundworm *C. elegans*, suggesting physiological regulation of maternal provisioning. Compared to being fed *ad libitum* (AL), worms cultured under DR are smaller, delay reproduction, and produce fewer but larger progeny. Furthermore, progeny of DR worms are buffered from advearse consequences of early-larval starvation: They grow faster and are more fertile than control progeny following extended starvation, suggesting a fitness advantage. Nutrient availability is assessed during oogenesis, in late larvae and young adults, rather than affecting a set point in young larvae. Insulin-like signaling mediates effects of nutrient availability on progeny size. Reduced signaling through the insulin-like receptor *daf-2*/InsR in the soma causes constitutively large progeny, and its effector *daf-16/*FoxO is required for this effect. Additional regulators of energy homeostasis including the nuclear hormone receptor *nhr-49/*Hnf4*, pha-4/*FoxA, and *skn-1/*Nrf are also required for progeny size plasticity in response to diet. Disruption of *daf-2*/InsR does not require *nhr-49*/Hnf4, *pha-4*/FoxA, or *skn-1*/Nrf for increased embryo size, suggesting they act upstream or in parallel to insulin-like signaling. This work presents an invertebrate model for maternal effects of DR, demonstrates potentially adaptive intergenerational phenotypic plasticity, and identifies conserved pathways mediating these effects.

W4013A TGFβ and prostaglandin synthesis in *C. elegans*: linking environmental cues to sperm motility function. *Muhan Hu*, Michael Miller. University of Alabama at Birmingham, Birmingham, AL.

Sexual reproduction is critical for maintaining population diversity and species survival. Environmental exposures are thought to influence animal fertility, but the underlying mechanisms are not well understood. Fertilization depends on sperm guidance mechanisms for locating maturing oocytes within the oviduct. The signaling pathways that mediate sperm guidance have been well studied in marine species, but less is known in internally fertilizing animals, such as *C. elegans*. We have shown that *C. elegans* oocytes synthesize specific classes of F-series prostaglandins (PGFs) that guide migrating sperm toward them. These PGFs are synthesized via an unknown and possibly evolutionarily conserved metabolic pathway. The DAF-7 TGFβ homologue acts in ASI sensory neurons, downstream of ascaroside pheromones, to modulate oocyte PGF synthesis, linking environmental perception to sperm performance. Loss of the DAF-1 type I TGFβ receptor causes sperm guidance defects and decreased PGF synthesis. Here we show that the PGF synthesis phenotype can be suppressed by *daf-3* co-SMAD loss. DAF-3 activity is required in part within the germ line, suggesting DAF-3 transcriptional targets in oocyte precursors modulate PGF metabolism. To identify these TGFβ targets, we conducted RNA sequencing analyses of wild type, *daf-1* mutant, and *daf-1;daf-3* mutant hermaphrodites. Currently, RNAi screens are being used to test whether the TGFβ target (direct or indirect) genes play roles in PGF metabolism. Genome-editing strategies are ongoing to investigate how TGFβ signals are transduced to the germ line. Mass spectrometry approaches are being developed to help identify biochemical steps mediated by TGFβ. These efforts are providing insight into the molecular mechanisms of fertilization and the link between environmental factors and sperm function.

W4014B Characterization and identification of new genes required for sperm activation in *C. elegans*. *A. R. Krauchunas*[1], E. Mendez[1], D. Chen[1], J. Parry[1], J. Ni[1], S. Gu[1], G. Stanfield[2], A. Singson[1]. 1) Rutgers, The State University of New Jersey, Piscataway, NJ; 2) University of Utah, Salt Lake City, UT.

Successful fertilization requires that sperm are activated prior to contacting an egg. In *C. elegans*, this activation process, called spermiogenesis, transforms round immobile spermatids into motile, fertilization-competent spermatozoa. Spermiogenesis in males uses the TRY-5 protease pathway, whereas in hermaphrodites it is controlled by the SPE-8 pathway. Here we describe the characterization of two new spermiogenesis-defective mutants. We show that *spe-43* is a new component of the SPE-8 pathway; *spe-43* hermaphrodites are self-sterile, while *spe-43* males show wild-type fertility. Consistent with other members of the *spe-8* class, *spe-43* hermaphrodite sperm can be trans-

activated by male seminal fluid.When *spe-43* spermatids are exposed to Pronaseto activate the sperm *in vitro*, they form long rigid spikes radiating outward from the cell periphery instead of forming a motile pseudopod confirming a defect in spermiogenesis.Using a combination of recombinant and deletion mapping and whole genome sequencing we identified a C>T mutation in F09E8.1 as the molecular lesion in *spe-43(eb63)*. A second allele *spe-43(jn5)* allows us to conclude that although the *spe-43* transcript exists in two isoforms, only the isoform predicted to encode a transmembrane domain and a large extracellular domain is necessary for its function in spermiogenesis.Unlike *spe-43*, our second mutant, *as41,* affects spermiogenesis in both sexes, suggesting that the mutated gene may be downstream of both the TRY-5 and SPE-8 pathways. Spermatids from *as41*mutants show no signs of *in vitro* activation in the presence of Pronase, failing to even form spikes. We are currently in the process of using a similar whole genome sequencing strategy to identify the molecular nature of *as41.*

W4015C A calcineurin-interacting protein regulates ovulation and male mating in C.elegans. *Sun-Kyung Lee*, Hana Jung, Joohong Ahnn. Hanyang University, Seoul, KR.

Substrate candidates for calcineurin, a serine/threonine phosphatase, have been screened by yeast two-hybrid assays. We found that a 85 kDa basic protein interacted with the catalytic domain of TAX-6. The calcineurin interacting protein, cnp-2, is expressed in head neurons, posterior intestine, spermatheca-uterus valve in hermaphrodites, and in spicule retractor neurons, rays and at the end of fan, which are mating behavior-mediated organs, in males. cnp-2 is required in the ovulation, arrangement of eggs, ray structure and mating behaviors, and is critical in the mating efficiency and sperm activation. Expression of IP3 signaling molecules was significantly decreased in hermaphrodite reproductory organs of *cnp-2* mutants, which suggest that IP3 signaling is suppressed when cnp-2 was absent. We are currently further investigating functions of cnp-2 on reproductive process.

W4016A Identification and Characterization of Genes Essential for *C. Elegans* Sperm Guidance. *S. B. Legg*, M. A. Miller. University of Alabama at Birmingham, Birmingham, Alabama.

Fertilization is the fusion of sperm and oocyte to initiate embryonic development. It can occur internally or externally, depending on the animal species. In internally fertilizing animals, sperm must locate freshly ovulated oocytes within the convoluted architecture of the female reproductive tract. These sperm guidance mechanisms are not well understood. Our lab has shown that *C. elegans* oocytes secrete F-series prostaglandins (PGFs) to guide sperm to the spermatheca. These PGFs are synthesized independent of the canonical cyclooxygenase cascade, which catalyzes PGF synthesis in mammals. We have recently shown that cyclooxygenase null mice and worms produce similar PGF isomers, suggesting that a second PGF enzymatic pathway exists. Moreover, we have identified these PGF isomers in human ovarian follicular fluid. The goal of my project is to identify genes critical for *C. elegans* sperm guidance and in particular, PGF metabolism.

In order to identify genes essential for sperm guidance in *C. elegans*, we have devised an *in vivo* screening method using RNAi and a one hour sperm guidance assay. *C. elegans* oocytes synthesize sperm-guiding PGFs from PUFA precursors provided in yolk, so the screen will focus on genes expressed in the adult germ line (Reinke et al., 2004). N2 hermaphrodites are administered RNAi by the feeding method. L4 stage worms are added to the plates and kept at 25ºC for 36-48 hours. RNAi hermaphrodites are anesthetized and incubated with wild-type males stained with MitoTracker Red CMXRos. Mated hermaphrodites are removed from males and allowed to rest for an hour. Fluorescent sperm distribution within the uterus is viewed on plates using a stereomicroscope. In controls, sperm are observed in two foci roughly equidistant to the vulva, corresponding to the two spermathecae. Deficiency in PGF synthesis causes more uniform sperm distribution throughout the uterus. This strategy permits screening of about 50-100 RNAi clones per month. My project focuses on screening 266 germline genes on Chromosome II. Out of 75 RNAi clones screened to date, I have identified 10 clones that caused strong sperm guidance defects, and 11 clones that caused moderate defects. These RNAi clones correspond to genes implicated in diverse functions, including receptor-mediated endocytosis, protein secretion, calcium ion binding, and lipid storage. For selected positive clones, null mutations will be generated using CRISPR/Cas9. Transgenic and genetic mosaic experiments will be used to determine where these genes are expressed and function. Liquid chromatography tandem mass spectrometry methods will be used to determine if the genes modulate PGF metabolism.

W4017B PP1α phosphatase GSP-2 regulates meiotic chromosome segregation during spermatogenesis in *C. elegans*. *Yi-Hsiu Lin*[1], Jui-Ching Wu[1,2]. 1) Department of Clinical Laboratory Sciences and Medical Biotechnology, National Taiwan University, Taipei, Taiwan; 2) Department of Laboratory Medicine, National Taiwan University Hospital, Taipei, Taiwan.

During spermatogenesis, it is crucial to properly partition duplicated chromosomes into four haploid cells with two consecutive divisions. It is unclear if the two chromosome segregation events are regulated by the same mechanism. Previously it is shown that two male-specific PP1 phosphatases are specifically required for chromosome segregation in meiosis II, suggesting the two chromosome segregation events, which separate homologs and sisters respectively, are regulated by different mechanisms. Here we investigate the roles of GSP-1 and GSP-2, the *C. elegans* homologs of the ubiquitously expressed PP1β and PP1α, in male meiotic divisions. Interestingly, despite high sequence identity, *gsp-1* and *gsp-2* mutant male worms show very different effects in spermatogenesis. Although *gsp-1* mutant hermaphrodites are sterile, males lacking *gsp-1* are completely fertile and show normal progression of sperm meiotic divisions in our analyses, indicating GSP-1 primarily functions in oocyte production. Contrarily, male worms lacking *gsp-2* show high penetrance of male infertility. Examination of mature sperm revealed high percentage of sperm with abnormal nuclei and variable sizes produced by *gsp-2* mutant males. By immunofluorescence staining, *gsp-2* mutant male gonads exhibited a variety of abnormal chromosome morphology at division zones, indicating chromosome segregation defects during male meiosis. To further investigate the defects, we examined the progression of male meiotic chromosome segregation in live *gsp-2* mutant males. In the absence of GSP-2, the chromosomes fail to be organized at the center of the cell, causing a delay of anaphase I onset. Furthermore, during anaphase I, the chromosomes are either separated rapidly without typical dumbbell-shape arrangement, or at a reduced speed with lagging chromosomes. During the second division, onset of anaphase II is also delayed and chromosome bridges were

detected during separation. These results suggest GSP-2 is required for proper orientation of chromosomes during both meiotic divisions. In addition to defects in chromosome separation, we found paired chromosomes are often disengaged into multiple chromosomal bodies in *gsp-2* mutant spermatocytes during meiosis I, indicating premature cohesion removal during first meiotic division. We reasoned GSP-2 might be required for protecting sister chromatid cohesin by restricting the localization of Aurora B kinase AIR-2 as described in oocytes. Consistent with this, we found AIR-2 is spread to the sister chromatids in the absence of GSP-2. These results suggest GSP-2 antagonizes AIR-2 function to regulate timely cohesin removal during male meiosis as in female meiosis. Taken together, we conclude that GSP-2 PP1 phosphatase is required for both chromosome orientation as well as stepwise chromosomal cohesion removal during male meiotic divisions.

W4018C PAM-1, the C. elegans ortholog of the puromycin sensitive aminopeptidase, and autophagy pathways genetically collaborate to regulate gametogenesis. *A. Munie*, A. Cude, C. Trzepacz. Murray State University, Murray, KY.

Autophagy, the cell's recycling system, is a highly conserved and regulated biological process. Autophagy normally functions as a housekeeping role and is utilized to remove any damaged, malfunctioning, or unnecessary organelles, but can be stimulated in times of cellular stress. Starvation, hypoxia, and the accumulation of cytotoxic aggregates, such as those linked to neurodegenerative disorders such as Huntington's and Alzheimer's disease, are all remediated by autophagic mechanisms. Studies in a number of model organisms, including mice, fruit flies, and nematodes have identified numerous genes involved in mediating autophagy, including the Puromycin-sensitive aminopeptidase (*Psa*). The *Caenorhabditis elegans* orthologue of *Psa, pam-1*, governs fertility in the nematode. The gonads of adult worms harboring mutant *pam-1* alleles display several pheotypes indicating compromised worm gametogenesis, including a decreased brood size, increased embryonic lethality, and an expansion of the population of immature pachytene stage germinal nuclei toward the proximal end of the gonad. Because PAM-1 also functions in autophagic pathways, we examined the reciprocal involvement of autophagy in gametogenesis.

RNAi was employed to independently inhibit the expression of five conserved *C. elegans* autophagy genes: *ATG5/bec-1, ATG8/lgg-1. ATG7/atg-7, ATG18/atg-18,* and *VPS-34/vps-34*, in both wild-type N2 and *pam-1* strains, and adult animals were examined for changes in *pam-1*-influenced phenotype metrics. Inhibition of *vps-34* in N2 animals had a statistically significant effect on pachytene expansion; RNAi of the remaining autophagy genes had no discernible impact on the N2 aniamls. However, the independent inhibition of each of the autophagy genes in mutant *pam-1* animals results in a synergistic exacerbation of multiple fertility metrics, most consistently an expansion of the pachytene population. We are currently employing fluorescently-labelled transgenes to examine the colocalization of PAM-1 and the autophagy machinery in the gonad. Our data suggests a novel collaboration of PAM-1. and autophagy functions in mediating meiotic transitions and fertility in *C. elegans*.

W4019A Screening of compounds that can dissect the *C. elegans* spermiogenesis pathway. *H. Nishimura*[1], S. Nakamura[1], T. Tajima[1], K. Nakanishi[1], F. Ogawa[2], M. Omote[2]. 1) Department of Life Science, Setsunan University, Neyagawa, Osaka, JP; 2) Department of Pharmaceutical Sciences, Setsunan University, Hirakata, Osaka, JP.

For sexual reproduction in most animal species, spermiogenesis is an essential, post-meiotic event in which spermatids transform into spermatozoa. During *C. elegans* spermiogenesis, pseudopods extend from spermatids, and membranous organelles (MOs) are fused with the spermatid plasma membrane. *C. elegans* is so useful for studying spermiogenesis; in addition to easy availability of various genetic tools, we can use *in vitro* spermiogenesis system in a simple, chemically defined medium. This advantage allows us to use compounds that can directly control spermatid activation into spermatozoa to dissect the *C. elegans* spermiogenesis pathway.

Based on microscopic observation of Pronase-induced *in vitro* spermiogenesis, we screened a library of compounds with diverse structures. One compound, named DDI-1, blocked pseudopod extension, but not MO fusion with the spermatid plasma membrane (IC_{50} = ~30 µM). Since DDI-1 did not affect the proteolytic activity of Pronase towards FITC-casein, the compound seemed to target a spermatid protein(s) that is involved in pseudopod extension.

Moreover, we examined brood sizes after incubation of L4 hermaphrodites with DDI-1 at 20ºC for 48 h in liquid culture. The compound-treated worms, unexpectedly, produced F1 progeny ~50% more than control worms. As spermatids were released from DDI-1-treated males and then activated with Pronase, spermiogenesis normally occurred. These data suggest that, in liquid culture, DDI-1 probably does not reach spermatids present within the male gonads and that this compound has an additional effect(s) on reproduction besides blocking spermiogenesis.

Currently we are producing a series of DDI-1 derivatives to identify its target(s) and keeping to screen the same library to obtain more compounds that affect spermiogenesis.

W4020B A role for sperm-gonad signaling in competition for reproductive success. *G. M. Stanfield*, J. M. Hansen. University of Utah, Salt Lake City, UT.

In *C. elegans*, fertilization occurs only within the spermathecae, specialized regions of the hermaphrodite gonad in which newly ovulated oocytes interact with stored sperm. Thus, a key determinant of male reproductive success is the ability of sperm cells to be present within the spermathecae at the time of ovulation. We have found that the divergent kinase COMP-1 functions in sperm to promote their residence within the spermathecae. Surprisingly, we detect only subtle defects in the directional migration of mutant sperm. Instead, *comp-1* sperm accumulate just outside the spermathecae, and largely fail to gain entry until self sperm are depleted. Both sperm usage and localization defects in *comp-1* mutants are limited to competitive contexts, raising the question of how sperm signal to other sperm to influence their function. Our data suggest that rather than interacting directly, sperm resident within the sperm storage organ may signal through the female gonad. Bidirectional communication between sperm and the female gonad is known to be used to recruit sperm to migrate toward oocytes and to couple ovulation to the presence of sperm. We find that a subset of these signaling pathways also influence sperm competition, and that wild-type and *comp-1*

sperm respond differentially to perturbations of the signaling environment. For example, wild-type sperm, unlike those of *comp-1*, show defects within older hermaphrodites that have depleted their sperm. While oocyte-derived prostaglandins promote migration of wild-type sperm, prostaglandins appear to inhibit *comp-1* mutant sperm. Mutants for *spe-9* generate sperm that localize correctly but fail to fertilize oocytes; when *spe-9* sperm is present in the spermathecae, *comp-1* sperm migration is rescued, but wild-type sperm migration is perturbed. Thus, it seems that sperm signal their presence using a mechanism distinct from release of MSP, but potentially involving *spe-9*. In addition to analyzing known signaling pathways, we are testing whether different substrates for migration, such as fertilized eggs vs. unfertilized oocytes, are differentially permissive for sperm migration or affect the outcome of competition.

W4021C Are all hermaphroditic nematodes like *C. elegans*? Lessons from *Rhabditis* hermaphroditic nematodes that produce sperm and oocytes simultaneously. *XIAOXUE LIN*, Caitlin McCaig. College of William and Mary, Williamsburg, VA.

On multiple separate occasions, ancestral male/female nematode species have convergently evolved self-fertile hermaphroditism. In *C. elegans,* hermaphrodites achieve self-fertility by producing sperm as larval L4s, storing their sperm, and then making a one-time switch to oogenesis. Here we report that hermaphrodites of the same family but in the *Rhabditis* clade, specifically *Rhabditis* sp. SB347, JU1782, and JU1783, achieve self-fertility by continuously producing both sperm and oocytes from L4 and throughout the adult lifespan.

In the hermaphrodite germlines of these male/female/hermaphrodite *Rhabditis* species, we find distinct clusters of cells alongside the developing oocytes. In contrast, these cell clusters are not present in females, which implies their sperm-related function. The number of cells per cluster increases in a distal to proximal fashion most often in a pattern of 1, 2, 4, or 8 cells. In addition, many clusters contain dividing cells with tubulin spindles, suggesting that they proliferate along the germline. Immunocytochemistry shows that the expression of major sperm protein (MSP) is found only in the late clusters (often in the vicinity of the -1 to -3 oocyte). Our analysis suggests that the early cell clusters are mitotic progenitors of meiotic spermatocytes in the late clusters. The mitotic, undifferentiated character of the progenitor cells leads us to conclude that they are analogous to the recently clarified transit amplifying (TA) cells in the *C. elegans* mitotic region. However, unlike in *C. elegans*, the presumed TA cells in *Rhabditis* hermaphrodites exist in isolated clusters, physically distant from both the stem cell niche and other cell clusters. Such mitotic cluster formation presents a unique opportunity to study TA cell development. Ongoing studies of this divergent mechanism of spermatogenesis are characterizing both protein and RNA expression of conserved regulators of the cell cycle and the germ cell differentiation. By understanding the cellular and genetic pathways in non-*C. elegans* nematode species, we hope to elucidate germ cell development and differentiation in a novel evolutionary context.

W4022A Characterization of the germline stem cell niche in *C. elegans* males. *S. L. Crittenden*[1,2], C. H. Lee[1,2], I. Mohanty[1], J. Kimble[1,2]. 1) University of Wisconsin-Madison, Madison, WI; 2) HHMI.

In *C. elegans*, the distal tip cell (DTC) niche maintains germline stem cells (GSCs) in both sexes. In addition, the same GSC regulators are used in both sexes (GLP-1/Notch signaling, the LST-1and SYGL-1 downstream effectors and FBF RNA-binding proteins). Yet, there are differences between the sexes. Hermaphrodites have a single DTC while males have two, and DTC expression of GLP-1/Notch ligands differs (1). Male germ cells have a faster cell cycle than hermaphrodites, and the male progenitor zone is longer (2).

We used a GFP marker to examine adult male DTC architecture. We find that each DTC has a cap region extending over 3-4 cell rows, similar to the extent of the cap in the single hermaphrodite DTC (3). The male DTCs also form a plexus of processes that intercalate between germ cells. Yet the male plexus is longer than the hermaphrodite plexus.

We examined the transcriptional response to GLP-1/Notch signaling in male germ cells with single molecule FISH to *sygl-1* (4). As in hermaphrodites (4,5), *sygl-1* transcripts are spatially restricted to the distal progenitor zone. Preliminary results indicate that *sygl-1* transcripts extend further proximally in males than in hermaphrodites. Using the *emb-30* assay that revealed a distal pool of undifferentiated germ cells in hermaphrodites (6), we find that males have an expanded distal pool, which correlates with the expanded *sygl-1* transcriptional response.

W4023B Molecular and genetic analysis of the *ego-3* gene reveals a critical role for HSP90 in GLP-1/Notch signaling in the *C. elegans* germline. *J. Lissemore*[1], M. Edgley[2], S. Flibotte[2], J. Taylor[2], V. Au[2], E. Connors[3], Y. Liu[3], L. Qiao[3], B. Yang[3], O. Zucaro[1], J. Krach[1], M. Lee[1], D. Moerman[2], E. Maine[3]. 1) John Carroll University, University Heights, OH; 2) Dept. of Zoology, University of British Columbia; 3) Biology Dept., Syracuse University.

glp-1 encodes a Notch family transmembrane receptor required for mitotic proliferation of the *C. elegans* germline. Mutations in *glp-1* lead to reduced germline proliferation, with strong loss-of-function mutations rendering hermaphrodites sterile. *ego-3* was identified in a screen for genetic enhancers of the mild proliferation defect in *glp-1(bn18ts)* mutants raised at 20°C. The screen was designed to identify mutations that decrease GLP-1/NOTCH signaling in the germline. The best studied allele of *ego-3, ego-3(om40)*, has a complex recessive phenotype that includes reduced and delayed larval germline proliferation, slow development characterized by extended larval period, proximal germline proliferation in adults, delayed and abnormal gamete formation, and a severe mobility defect that improves to nearly wildtype mobility in adults. Another allele obtained by non-complementation, *ego-3(om118)*, has a recessive embryonic lethal phenotype. To identify *ego-3(om40)*, we first carried out three-factor and SNP mapping, which placed *ego-3* on chromosome VR, to the left of *unc-61* and close to *daf-21*, in a region

containing 14 known protein-coding genes. We next conducted whole genome sequencing (WGS) on homozygous *ego-3(om40)* mutants. WGS identified one sequence variant within the protein coding region of one gene in the mapped region, *daf-21*, which encodes the *C. elegans* ortholog of the molecular chaperone HSP90. The sequence variant is a T>A transition causing an I>N non-conservative missense mutation. Sanger sequencing confirmed this mutation; subsequently, we identified the *ego-3(om118)* mutation, a 20 bp non-tandem duplication within the same exon containing the *ego-3(om40)* mutation. *ego-3(om118)* is predicted to cause a frameshift and introduce a premature termination codon. *ego-3(om40)* fails to complement *daf-21(ok1333)*, a putative null allele carrying a large deletion. *daf-21* RNAi partially phenocopies *ego-3* in a wildtype background, causing sterility, embryonic lethality, reduced germline proliferation in the larva, and, in some adults, proximal germline proliferation. Thus, by various genetic and molecular criteria, we have confirmed the identity of *ego-3* as *daf-21*. While HSP90 has long been known to participate in a variety of oncogenic, proliferative signaling pathways in metazoans, our results provide the first evidence that HSP90 plays a role in GLP-1/NOTCH signaling and in mitotic proliferation in the *C. elegans* germline.

W4024C Investigating the remodeling of *C. elegans* primordial germ cells into germline stem cells. *C. Maniscalco*, J. Nance. NYU School of Medicine, New York, NY.

Germ cells allow us to transmit our genome to future generations. The embryonic precursors of germ cells, called primordial germ cells (PGCs), are set aside early during development and are subjected to unique regulation, such as transcriptional repression, so that differentiation does not occur. In order to produce gametes, quiescent PGCs must activate and transition into dividing germline stem cells (GSCs). The mechanism of this transition, however, is poorly understood. The two embryonic PGCs in *C. elegans* extend large cytoplasm-filled lobes into the surrounding endoderm; lobes and their contents are subsequently removed and digested by endodermal cells (our unpublished observations), suggesting that they may function as a means for PGCs to discard unwanted components before they transition to GSCs. In support of this hypothesis, live imaging results show that PGC lobes concentrate certain cellular components, such as most of the mitochondria, before the lobes and their contents are pinched off and eaten by adjacent endodermal cells. In search of a mechanism for lobe formation, I observed that non-muscle myosin (NMY-2), a component of the contractile ring in dividing cells, forms a ring at the neck between PGCs and their lobes. This led us to hypothesize that lobes form when a contractile ring-like structure constricts the cell body into two halves. I am currently testing this hypothesis using temperature-sensitive mutations in components required for contractile ring function. By blocking formation of PGC lobes, I hope to determine if they function in the transition of PGCs to GSCs in the developing embryo.

W4025A Regulation of germline stem cell maintenance by S6-Kinase in *C. elegans*. *D. Roy*, E. Jane Hubbard. New York University School of Medicine, New York, NY.

Accumulation and maintenance of stem cells is key to proper organogenesis during development and to tissue homeostasis in adulthood. However, our understanding of signals regulating these cells remains incomplete. The *C. elegans* germ line provides a simple model for studying cellular and molecular regulation of the accumulation and maintenance of germline stem/progenitor cells. Previously, our lab established that the Target of Rapamycin (TOR) pathway: *let*-363/TOR, *daf*-15/RAPTOR, *rsks*-1/p-70-S6-Kinase (S6K) and *ife*-1/eukaryotic initiation factor-4E (eIF4E), and ample food, promote the accumulation of proliferative germ cells during larval development.

Additionally, and unexpectedly, we found that S6K acts in concert with GLP-1/Notch to maintain undifferentiated germ cells. GLP-1/Notch signaling prevents differentiation and/or maintains proliferative germ cells. We found that loss of S6K enhances and suppresses specific phenotypes associated with reduced and elevated *glp-1* activity, respectively. More recently we found that, similar to its role in promoting germ cell accumulation, S6K acts germline-autonomously and requires a conserved TOR phosphorylation site to prevent germ cell differentiation. However, neither TOR nor eIF4E shared the same genetic interaction with *glp-1*. These results suggest that the role of S6K in preventing differentiation may be a special feature of the S6K branch of the TOR pathway.

S6K is highly conserved. While its role as translational regulator is well characterized, examples of S6K-mediated cell fate regulation are limited. Therefore, we are using our genetics-based functional assays to undertake both candidate and unbiased approaches to determine the molecular mechanism by which S6K prevents differentiation. Others have shown that, like loss of S6K, reduced *cye-1*/Cyclin-E or MAPK activity can enhance *glp-1*. However, we found that neither acts in a simple linear fashion with S6K to regulate cell fate. We are currently testing additional candidates, including translational regulators, for their roles in germ cell fate maintenance and functional interaction with S6K. In parallel, we are conducting genome-wide genetic and proteomic screens to identify candidates that will be tested for their role in cell fate regulation.

W4026B GLD-1, FOG-2, and the Emergence of Self-fertility in *C. elegans*. *E. Haag*[1], S. Hu[1], L. Ryan[2], T. W. Lo[2]. 1) Univ. of Maryland, College Park, MD; 2) Ithaca College, Ithaca NY.

Germ cell sex determination in *Caenorhabditis* nematodes is regulated by a network of translational repressors [1]. In species where the XX female has evolved self-fertility, this network is reconfigured to allow limited spermatogenesis. This is achieved by changes to both properties of repressor proteins and in the *cis*-regulatory sites of their client mRNAs [e.g. 2]. Here, we focus on a highly conserved mRNA-binding protein, GLD-1, and its *C. elegans*-specific cofactor, FOG-2. Previous work has implicated both proteins in the translational regulation of *C. elegans tra*-2, a key promoter of female fate [3-5]. The STAR family protein GLD-1 targets hundreds of mRNAs in addition to *tra-2* [6]. Consistent with this, GLD-1 is not only required for XX spermatogenesis, but for other aspects of meiosis and oocyte differentiation. These oocyte-related roles are conserved across the *Caenorhabditis* genus. In contrast to this pleiotropy, the function of FOG-2 is restricted to specification of XX spermatogenesis [7]. *fog-2* is the product of a recent gene duplication, and is found only in *C. elegans*, consistent with it representing an essential player in the emergence of the novel self-fertile phenotype [8,9]. We seek to understand the molecular mechanism of how FOG-2 affects sex determination, and in particular how it modifies the activity of GLD-1 and/or its target mRNAs. We used CRISPR/Cas9 to introduce

small epitope tags into the endogenous TRA-2 and FOG-2 proteins, and are currently using these to examine expression in wild-type and mutant contexts. We are also working to identify proteins that bind to FOG-2, and to compare mRNAs associated with FOG-2 to those already known for GLD-1.

W4027C Novel regulation of *C. briggsae* spermatogenesis. *Katharine Pelletier*[1], Keith Reidy[1], Jill Dewar[1], Carlos Carvalho[2], Dave Pilgrim[1]. 1) University of Alberta, Edmonton, Alberta, CA; 2) University of Saskatchewan Saskatoon, Saskatchewan, CA.

The evolution of novel traits relies on heritable changes in gene content or gene expression, but the processes by which these occur is not always clear. Sex determination is a particularly interesting trait with which to model these processes because its regulation seems to be subject to rapid evolution. Androdioecy, or a species ability to make an ovotestis in an otherwise female animal, has independently evolved three times in the *Caenorhabditis* nematode clade from a dioecious ancestor. By comparing the genetic regulatory network allowing for androdioecy in two species, *C. elegans* and *C. briggsae*, to their dioecious close relatives, we hope to understand how the novelty arose. Sex determination is well understood in *C. elegans*, and we have been using similar molecular and genetic tools to understand hermaphroditism in *C. briggsae*.

Forward genetic screens allowed genetic identification of the *C. briggsae* orthologs of *C. elegans* genes (*tra, fem*) required for somatic and gonadal sex determination, but unlike in *C. elegans*, none of the feminizing mutants blocked spermatogenesis in the female ovotestis. A second screen, looking for suppressors of masculinizing mutants identified several phenotypes not seen in *C. elegans*. Many of these suppressors permit the development of XX hermaphrodites and XO males in a masculinized *tra-2* background, in contrast to *C. elegans* feminizing mutants where XO animals are feminized. Mutant alleles with this phenotype have been identified both within know sex determination genes, such as *fem-3*, and in novel regulatory loci. Through examination of these alleles, we will gain key insights into differences in *C. briggsae* sex determination in both the soma and the germ line. We will present our current understanding of somatic and germ line sex determination in *C. briggsae* and compare that to what is known in *C. elegans.* This illustrates how we can use comparative genomics within the *Caenorhabditis* clade to better understand the evolution of genetic regulatory network.

W4028A TGFß and insulin-like signaling mediate the feeding state-dependent expression of the food chemoreceptor ODR-10 in *C. elegans* males. *Emily R. Wexler*, Deborah A. Ryan, Douglas S. Portman. University of Rochester, Rochester, NY.

The biological mechanisms by which neural circuits are modulated by an animal's sex ("gender") is poorly understood. We have previously found that *C. elegans* males and hermaphrodites differ in their response to several odorants detected by shared circuitry. In particular, hermaphrodites are more attracted than males to the odorant diacetyl, a food cue sensed by the chemoreceptor *odr-10*, expressed in the AWA sensory neuron. Recently, we have shown that regulated *odr-10* expression underlies sex differences in diacetyl attraction. In adult males, *odr-10* expression is significantly reduced compared to hermaphrodites, promoting the prioritization of exploratory behavior over feeding. Moreover, transient starvation upregulates *odr-10* in males to promote feeding. We have identified the TGFβ and the insulin-like signaling pathways as regulators of *odr-10* expression in males. Males with mutations in the TGFβ ligand *daf-7* or the downstream SMAD *daf-8* have increased expression of *odr-10.* In contrast, these mutations have no apparent effect on *odr-10* expression in hermaphrodites. Animals with mutations in *daf-5*, a transcription factor inhibited by DAF-7 signaling, show decreased expression of *odr-10*; moreover, *daf-5* males show no increase in *odr-10* expression in response to starvation. Likewise, loss of the insulin receptor *daf-2* results in increased *odr-10* expression in males and *daf-16* mutant males do not upregulate *odr-10* upon starvation. These findings suggest the TGFβ and insulin-like signaling pathways regulate feeding-state-mediated changes in *odr-10* expression in a sex-dependent manner. The apparent sensitivity of males to these signals suggests that the sex determination pathway intersects with TGFβ and insulin-like signaling to bring about state-dependent changes in odr-10 expression and behavior.

W4029B PUP-1/CDE-1 and PUP-2 poly(U) polymerases function redundantly in germline development in *C. elegans*. *Y. Li*, M. Snyder, E. Maine. Syracuse University, Syracuse, NY.

Poly(U) polymerases (PUPs) add uridine to the 3'end of RNAs, a modification that correlates with reduced RNA stability in many organisms. Targets of uridylation include mRNAs and small RNAs, including small-interfering (si) RNAs and unmethylated micro (mi) RNAs. Despite the prevalence of uridylation, our knowledge of its developmental importance is limited. Three members of the PUP family have been identified in *Caenorhabditis elegans* [1]. Two have been studied in some detail. PUP-1/CDE-1 (co-suppression defective) targets a subset of siRNAs and is expressed in the germ line [2]; PUP-2 activity regulates a subset of miRNAs that act in the soma [3, 4]. Despite these distinct functions, we find that PUP-1/CDE-1 and PUP-2 are required redundantly in meiotic germ cells. We used the CRISPR-Cas9 system to generate a double knockout of *pup-1/cde-1* and *pup-2* [*pup-1(0) pup-2(0)*] and then compared its phenotype to those of *pup-1(0)* and *pup-2(0)* single mutants. The single mutants have numerous defects that are present additively in the double mutant. In addition, we observe unique

phenotypes in the double mutant. Under conditions of temperature stress, *pup-1(0) pup-2(0)* hermaphrodites produce progressively smaller numbers of progeny and become sterile within three generations. The majority (~93%) of those sterile adults contain no germ cells. In addition, meiotic chromatin regulation is abnormal: in *pup-1(0) pup-2(0)* males, the histone H3 lysine 9 dimethylation (H3K9me2) modification is elevated from pachytene stage of first meiotic prophase until late spermiogenesis compared with controls. In keeping with delayed H3K9me2 removal, developing *pup-1(0) pup-2(0)* sperm progress through spermiogenesis relatively slowly compared with controls. Small RNAs are known to impact both germline survival and H3K9me2 regulation. We observe PUP-2 protein expression in germ line cytoplasm, particularly in developing oocytes. Taken together, our findings suggest that PUP-1 and PUP-2 function redundantly to ensure germline survival and chromatin regulation, perhaps by modulating small RNA levels. We are working to distinguish between alternative hypotheses for how PUP-1 and PUP-2 activities promote germline survival and chromatin regulation.

W4030C Analysis of germ cell proliferation and germline histone dynamics in *C.elegans*. *Simona Rosu*, Orna Cohen-Fix. NIH-NIDDK, Bethesda, MD.

The *C.elegans* adult contains a renewable pool of germ cells that make up the proliferative zone (PZ), which contains mitotically dividing cells. From this pool, cells enter meiosis and differentiate, ensuring continued production of oocytes. To date, studies on the PZ have utilized mainly fixed samples. Consequently, many questions remain about the operation of the PZ: where and how large is the stem cell pool? Is there a transit-amplifying population of germ cells? How is the number and rate of cell divisions regulated during germline proliferation? To investigate these questions, I have constructed a strain containing germline-expressed histone H2B::Dendra. Dendra is a green-fluorescing protein, which, when stimulated by laser light at 405 nm, photo-converts to red fluorescence. I have worked out a protocol to individually immobilize live worms and photo-convert selected germ cell nuclei, recover the worms to plates, and image the same worms many hours later. This allows me to determine the fate of the converted cells and their daughters arising from cell division. In the worm strain used, the entire PZ contains ~200 cells. Preliminary results indicate that a pool of 40-70 cells at the distal tip of the PZ expands an average of 2.6 times in about 8 hours, filling the majority of the PZ in this timeframe. A pool of cells in the middle of the PZ expands an average of 1.6 times in the same timeframe, indicating a subset of cells in this region divide, and some do not. This entire labeled pool originally in the mid-PZ moves proximally, with ~60% of the cells already entering meiosis. Thus the mid-PZ is unlikely to contain stem cells. Finally, a pool in the proximal zone of the PZ has little to no expansion (1.1 times average), and the entire pool moves proximally and enters meiosis. This is consistent with a model in which stem cells reside in the distal pool, and divide once in about 8 hours, giving rise to both daughters that self renew to remain in the stem cell pool, and daughters that will divide one more time as they move to the middle of the PZ, after which they cease divisions and enter meiosis. I am currently refining the analysis by converting smaller pools of cells. This work establishes the parameters that govern germ cell proliferation, which in future studies can be investigated under altered conditions or in mutant situations to determine regulatory mechanisms.

In addition, I am also using this tool to analyze histone dynamics during oogenesis.

W4031A Epigenetic Contributions to Homolog Recognition in Meiosis. *C. Doronio*, W. Kelly. Emory University , Atlanta, GA.

During meiosis, homologous chromosomes must correctly identify one another in order for proper alignment, synapsis, and recombination to occur. Improper pairing between chromosomes can lead to aneuploidies causing defective gamete formation and embryonic lethality. Currently, very little is known about homologous chromosome recognition and discrimination. There has been evidence supporting the role of DNA Double Strand Breaks (DSB) and homologous recombination in homolog pairing. However, mutants lacking the ability to form DSBs in *Drosophila* and *C. elegans* can still properly align homologous chromosomes, showing that DNA DSB independent mechanisms exist. *C. elegans* chromosomes have pairing centers composed of DNA sequences at ends of chromosomes that are required for efficient pairing, but the sequences are not all unique to single chromsomes. Furthermore, many organisms have highly repetitive genome content, making DNA sequence risky for homology searching. What forms the basis of homolog recognition?

The specific patterns of active transcription are distinct for each chromosome during meiosis. Peter Cook has previously proposed that aspects of such transcription patterns may provide a “bar-code” for homolog recognition, possibly through shared “transcription factories”(Xu and Cook, 2008). This hypothesis, while intriguing, is fundamentally difficult to test. However, transcription through a gene also “marks” that gene with specific epigenetic modifications, such as the methylation of Lysines 4, 36, and 79 on Histone H3 (H3K4me, H3K36me, and H3K79me, respectively). Thus regions of transcription and repression create alternating patterns of chromatin modifications, unique to each chromosome, that could be recognized by specific proteins and contribute to homology recognition. Indeed, the Nabeshima lab recently showed that pairing center-independent pairing defects were observed in the germline of *C.elegans mrg-1* mutants (Dombecki et al., 2011). *mrg-1* encodes a chromodomain protein whose mammalian homolog, MRG15 recognizes and binds to H3K36me. We are currently examining the role of histone modifications, and their cognate binding proteins such as MRG-1, in homology recognition and discrimination during meiosis.

W4032B Cortical microtubule dynamics in C. elegans oocytes. *C.-H. Chuang*, B. Bowerman. University of Oregon, Eugene, OR.

In many animal oocytes, meiotic spindles assemble in the absence of centrosomes to segregate chromosomes; yet, little is known about the origin of the spindle microtubules and the proteins that regulate spindle microtubule dynamics. We recently showed that in the absence of the microtubule depolymerizing kinesin KLP-7, extra microtubules accumulated around the oocyte chromosomes[1]. As others have reported[2], we also have observed a dramatic increase in microtubule levels throughout the oocyte cortex during meiosis I in *klp-7(-)* mutant oocytes. To further investigate microtubule dynamics, we are using spinning disc confocal microscopy in live oocytes to image GFP::β-tubulin during meiosis I in both wild-type and *klp-7(-)* mutants. In *klp-7(-)* oocytes, we found that microtubule foci were formed at the cortex during

prometaphase; some foci moved towards each other and then merged as larger microtubule organizing centers, while other foci moved into the assembling meiotic spindles. In wild-type oocytes, we observed that smaller and less dense of microtubule foci assembled in the cortex area; some foci still merged together, but fewer foci were recruited to the spindles relative to *klp-7(-)* mutants. We then used a GFP fusion to a spindle pole protein ASPM-1 to further investigate the dynamics of cortical microtubules in wild-type oocytes, and found that GFP::ASPM-1 also was present as multiple foci at the cortex. We are currently making an mKate2 fusion to ASPM-1 to further investigate the interplay of cortical microtubules and ASPM-1. In addition, we have found that the microtubule motor protein complex dynein influences oocyte cortical microtubule dynamics and is essential for proper organization of the oocyte meiotic spindle. In *dhc-1(-)* oocytes, cortical microtubules were present but did not appear to aggregate as microtubule foci. Moreover, in contrast to the barrel-shaped wild-type spindle, *dhc-1(-)* spindles collapsed soon after they started to assemble. After collapsing, the spindle microtubules spread around the cortex. Similarly, chromosomes distributed around the cortex, rather than aligning at the equator of the spindle barrel, based on analysis of an mCherry::Histone 2B fusion. We are currently further investigating how cortical microtubules and dynein contribute to oocyte meiotic spindle assembly.

W4033C Investigating Oocyte Meiotic Spindle Assembly and Bipolarity in *C. elegans*. *A. Schlientz*, B. Bowerman. University of Oregon, Eugene, OR.

Unlike mitotic spindles, oocyte meiotic spindles assemble in the absence of centrosomes. This phenomena sparks two interesting questions: 1) how do these acentrosomal spindles arise and 2) what dictates their bipolarity? To better understand acentrosomal oocyte meiotic spindle assembly in *C. elegans*, we are investigating the requirements for *cls-2*, a member of the CLASP family of microtubule binding proteins, and the kinesin-14 family members *klp-15/16*.

Using feeding RNAi mediated knockdown of *cls-2* and spinning disk confocal microscopy, we have observed a requirement for CLS-2 during oocyte meiotic spindle assembly, consistent with a previous study[1]. Interestingly, when using a GFP fusion to the spindle pole marker ASPM-1, we often see only a single focus of GFP::ASPM-1 signal, implying that CLS-2 may play an important role in either establishing or maintaining spindle bipolarity.

The *Drosophila* orthologue of *klp-15/16*, *non-claret disjunctional* (*ncd*), has been shown to play a role in oocyte meiotic spindle pole assembly, with split or extra poles forming in *ncd(-)* mutants. However, a role for this kinesin family in *C. elegans* has not been reported. Using feeding RNAi mediated knockdown of *klp-15/16* and spinning disk confocal microscopy, with our GFP::ASPM-1 pole marker, we observed what appears to be diffuse early spindle poles and a late establishment of spindle bipolarity, indicating that a role for this kinesin family in oocyte meiotic spindle pole assembly may be conserved across species.

W4034A Analysis of DLC-1 mediated regulation of the tumor suppressor protein GLD-1. *M. Ellenbecker*, E. Voronina. University of Montana, Missoula, MT.

Dynein light chain (DLC-1) was originally characterized as a cargo-binding component of the dynein motor complex that is involved in retrograde transport of mRNA and protein particles. More recent studies have revealed that DLC-1 interacts with a diversity of cellular proteins and likely also functions as an allosteric regulator in ribonucleoprotein complexes (mRNPs). Data from the Voronina lab suggests that DLC-1 regulates developmentally important mRNA expression by functioning as a cofactor to RNA binding proteins such as FBF-2 and GLD-1. GLD-1 is an RNA-binding protein that promotes germ cell differentiation during animal development by binding to and repressing translation of target mRNAs. This RNA regulatory function is essential for preventing ectopic proliferation in germ cells and *gld-1* mutant worms form germline tumors. Mammalian Quaking proteins are GLD-1 orthologs and function as potent glioblastoma multiforme tumor suppressors regulating the TGFβ signaling network that controls cell growth, proliferation and differentiation. RNA immunoprecipitation and microarrays or transcriptome wide sequencing experiments have identified hundreds of mRNAs as potential GLD-1 targets, however, the mechanism(s) of GLD-1 regulation of this diverse set of mRNAs is not well understood. We discovered that mutation in *dlc-1* gene predisposes nematode to tumor formation, GLD-1 target mRNAs are enriched in DLC-1 ribonucleoprotein complexes and that DLC-1 regulates translation of the GLD-1 target mRNA *mex-3*. Depletion of *dlc-1* using RNA interference disrupts the GLD-1-dependent control of germ cell proliferation and differentiation and biochemical assays show a direct DLC-1/GLD-1 binding interaction. Together, these data support the hypothesis that DLC-1 mediates the RNA regulatory and tumor suppressor functions of GLD-1 through a direct protein interaction. Some mechanistic possibilities for DLC-1 promoting the function(s) of GLD-1 are: regulating GLD-1 levels in germ cells, enhancing formation of GLD-1 mRNP complexes, cooperating in translational repression of GLD-1 mRNA targets and/or by mediating GLD-1 sub-cellular localization. We are currently using genetic and molecular biology techniques to determine how DLC-1 contributes to GLD-1 function *in vivo* and biochemical studies to elucidate the molecular details of the DLC-1/GLD-1 binding interaction. Since GLD-1 and mammalian Quaking proteins are closely related and their mutation causes cancer, molecular insights into germline tumor formation identified in this study using *C. elegans* as a model organism will be broadly relevant and significantly advance our understanding of human cancers.

W4035B Ubiquitin Conjugating Enzymes required for Ubiquitination of Paternal Organelles during post fertilization events. *Paola Molina*, Lynn Boyd. Middle Tennessee State University, Murfreesboro, TN.

The elimination of paternal organelles following fertilization is well conserved amongst metazoans, but the mechanism of organelle selection and process execution is not well understood. Previous studies conducted on *Caenorhabditis elegans* reported that the ubiquitin and autophagy pathways are involved in the elimination of paternal organelles. The current working model for the removal of paternal organelles in *C. elegans* is that membranous organelles (MOs) are ubiquitinated and cluster together with paternal mitochondria and together they are discarded through autophagy. Two different types of ubiquitin chains are found on the MOs in newly fertilized embryos. Lysine 48 chains are

found only during meiosis I and lysine 63 chains persist through all stages of meiosis and mitosis. These findings indicate that two different ubiquitination events are taking place during the tagging of paternal organelles. We have used transgenic nematodes with a GFP::Ub tag in the germline and RNAi to individually knockdown ubiquitin conjugating enzymes (UBC) to establish which UBC(s) is responsible for ubiquitinating the paternal organelles. The two different types of ubiquitin chains present on MOs suggest multiple ubiquitin events. Therefore, UBC combination knockdowns were also screened. The screen revealed *ubc-18/ubc-16* and *ubc-18/ubc-13/ubc-2* as the combinations that reduced the presence of GFP:Ub on MOs. Interestingly, *ubc-18* appears in both of our hits. Therefore, we took a closer look at WY34 (ku354) *ubc-18* mutants and stained for K48 and K63 ubiquitin chains. K63 chains were not affected by the absence of *ubc-18*. However, K48 chains were absent in the WY34 embryos. These results indicate that *ubc-18* is a key player in initial ubiquitination of paternal organelles.

W4036C Elucidating the Role of Securin in Regulating Separase during Cortical Granule Exocytosis. *C. Turpin*, M. LaForest, L. Uehlein-Klebanow, Q. Caylor, D. Mitchell, J. Bembenek. University of Tennessee, Knoxville, TN.

Meiosis is a tightly regulated series of events leading to the production of genetically distinct haploid gametes. A key player in this process is the cysteine protease separase (SEP-1). Known for its canonical role in chromosome segregation, recent studies suggest that SEP-1 has an additional function in vesicular trafficking during cell division. We hypothesize that cell cycle machinery known to control SEP-1 protease activity for chromosome segregation also controls its localization to the cortex and subsequent exocytic activity. Following spindle attachment and chromosome alignment during the meiotic M phase, the anaphase promoting complex/cyclosome (APC/C) is activated resulting in the degradation of SEP-1 inhibitory chaperone securin (IFY-1) and entry into anaphase I. In recent studies, we have observed that SEP-1 localizes to specialized vesicles called cortical granules and regulates their exocytosis during anaphase I. Cortical granule exocytosis is necessary for the process of eggshell formation. Before it appears on cortical granules, SEP-1 localizes to cytosolic filaments near the plasma membrane. We have shown that SEP-1 colocalizes with its inhibitor, IFY-1, on filaments during prometaphase, and both disassociate from these structures after the onset of anaphase I. Inhibition of APC/C activity prevents SEP-1 and IFY-1 from leaving the filaments, These data suggest the hypothesis that degradation of IFY-1 may regulate SEP-1 localization to vesicles. IFY-1 depletion does not prevent SEP-1 localization to cortical granules although exocytosis is impaired. To address whether IFY-1 degradation is required to allow SEP-1 translocation onto vesicles, we generated a non-degradeable IFY-1 (IFY-1^{DM}::GFP). Consistent with enhanced IFY-1 stability, IFY-1^{DM}::GFP is not completely degraded following anaphase I onset, remaining on chromosomes and in the cytoplasm into anaphase II. As expected, expression of IFY-1^{DM}::GFP causes embryonic lethality. Additionally, IFY-1^{DM}::GFP localizes to filaments normally and persists longer on these structures and chromosomes than wild type IFY-1 following the resumption of meiosis I. Interestingly, IFY-1^{DM}::GFP causes polar body extrusion failure, which could be related to defects in cortical granule exocytosis. In the future we will investigate how IFY-1^{DM}::GFP affects SEP-1 localization to cortical granules. This will provide insight into how key regulatory components of the cell cycle control SEP-1 localization to promote timely cortical granule exocytosis during anaphase I.

W4037A The Protease Activity of Separase Is Required for Both Chromosome Segregation and Membrane Trafficking During Anaphase. *Xiaofei Bai*, Diana Mitchell, Lindsey Klebanow, Joshua Bembenek. University of Tennessee, Knoxville, TN.

Chromosomal segregation and cytokinesis are tightly regulated processes involved in cell division. The cysteine protease separase is required for proper chromosomal segregation. Separase cleaves a subunit of the protein complex called cohesin, which keeps the sister chromatids together until the end of metaphase. In addition, separase is a key player in meiotic cortical granule exocytosis and vesicle trafficking during mitotic cytokinesis. RAB-11 is known to regulate both cortical granule exocytosis and exocytosis during cytokinesis. RNAi knockdown of separase impairs RAB-11 vesicular trafficking during both events. This raises the question of whether or not separase's protease activity regulates RAB-11 vesicle exocytosis. To address this question, we generated a catalytically inactive separase, SEP-1^{PD}::GFP. We found that the expression of SEP-1^{PD}::GFP causes chromosomal nondisjunction. Depletion of cohesin rescues this defect, indicating that cohesin cleavage is prevented by the inactive protease, possibly by a substrate trapping mechanism. To test whether SEP-1^{PD}::GFP also impairs RAB-11 vesicular trafficking during cytokinesis, we imaged the embryos that express RAB-11::mCherry and SEP-1^{PD}::GFP. Interestingly, expression of SEP-1^{PD}::GFP causes an abnormal accumulation of RAB-11 vesicles at the cleavage furrow site, similar to depletion of separase by RNAi. Moreover, we found that RAB-11 co-localized with both wild type separase and our protease dead mutant on cortical granules during meiotic anaphase I. We filmed SEP-1^{PD}::GFP expressing embryos during meiosis I to observe cortical granule exocytosis. Our results indicated that SEP-1^{PD}::GFP expression delayed the completion of cortical granule exocytosis. We tested possible genetic interactions between SEP-1^{PD}::GFP and core exocytic proteins. Our results indicate that the depletion of the t-SNARE syntaxin-4 (*syx-4*) further enhanced RAB-11::mCherry and SEP-1^{PD}::GFP accumulation on the cleavage furrow and the midbody. Moreover, we found an additive increase in embryonic cytokinesis failure relative to *syx-4* depletion or SEP-1^{PD}::GFP expression alone. These findings suggest that the protease activity of separase is required for the exocytosis of RAB-11 vesicles during mitotic cytokinesis and cortical granule exocytosis during meiosis I.

W4038B A Potential Role for Midbodies in Developing Tissues of *C. elegans*. *J. N. Bembenek*[1], X. Bai[1], B. C. Chen[2], R. Simmons[1], C. Turpin[1], L. Uehlein[1], D. Mitchell[1], E. Betzig[2]. 1) University of Tennessee, Knoxville, Knoxville, TN; 2) Janelia Research Campus, HHMI, Ashburn, VA.

The midbody forms at the end of cytokinesis and facilitates abscission, the final separation of the daughter cells. Midbodies have been implicated in several cellular processes in addition to abscission including cell fate, dorsoventral axis formation, neurite growth, and apical polarity during epithelial lumen formation. To investigate midbody function we examined midbody fate in the invariant lineage of the *C. elegans* embryo. Live-cell imaging has revealed unique and tissue-specific patterns of the fate of the midbody and different midbody components. In early embryo cell divisions, midbody flank proteins are lost from the midbody soon after cytokinesis while proteins associated with the midbody ring persists for much longer. A dramatic shift in midbody behavior is observed in several tissues at around the 300-cell stage

when the embryo undergoes global morphogenetic changes. In two lumen-forming tissues, the gut and pharynx, midbodies form and migrate to the apical midline. This midbody migration event coincides with previously characterized polarization events in gut epethelia. Upon reaching the intestinal midline the midbody ring is internalized and disappears; however, the Aurora B kinase, AIR-2, remains on the apical surface for over an hour after polarization. A similar apical localization pattern is observed for AIR-2 in the pharyngeal primordium. AIR-2 also localizes to midbodies in the sensilla primordium, which aggregate in foci over multiple successive divisions. AIR-2 persists along the leading edge of developing dendrites as they migrate towards the anterior end of the embryo and extend as dendritic processes. Other midbody markers are either internalized and degraded or maintained with AIR-2 in a tissue-specific manner. Inactivation of the central spindle organizer, *spd-1*, disrupted Aurora B kinase localization to the midbody as expected. However, Aurora B kinase was still capable of accumulating on the apical surface possibly by localizing to centrosomes. Inactivating several fast-inactivating temperature sensitive cytokinesis mutants late in embryogenesis causes severe morphogenesis defects. We hypothesize that the midbody and specific cytokinesis regulators such as AIR-2 may regulate the final interphase architecture of a terminally dividing cell.

W4039C TPXL-1 mediates aster-based clearing of contractile ring proteins from the cell poles during cytokinesis. *E. Zanin*[1], K. Oegema[2]. 1) Biozentrum der LMU München, München, DE; 2) Ludwig Cancer Research and Department of Cellular and Molecular Medicine, University of California, San Diego, La Jolla, CA 92037.

In the last step of cell division, a process called cytokinesis, the mother cell splits into two daughter cells. During cytokinesis a contractile actin-myosin ring forms beneath the plasma membrane around the cell equator. To coordinate cytokinesis with chromosome segregation, the contractile ring assembles in response to signals from the mitotic spindle. A stimulatory signal promotes cortical contractility by activating RhoA at the cell equator. At the same time, an inhibitory signal emanating from the centrosomal microtubule asters suppresses contractility at the cell poles. Attempts to identify the molecular basis of the inhibitory signal have been hindered by the absence of a robust assay. To address this problem, we established an assay for aster-based suppression of contractility in the *C. elegans* embryo. Using this assay, we identified TPXL-1, the homologue of TPX2, to be essential for aster-based clearing of contractile ring proteins from the cell poles. TPXL-1 is an aurora A kinase activator that localizes to the centrosomal microtubule asters. In *tpxl-1* mutant embryos the kinetochore microtubules are extremely short, which results in a short mitotic spindle at anaphase onset. To determine whether the short mitotic spindle or *tpxl-1* depletion itself causes defects in aster-based suppression, we increased spindle length in *tpxl-1* mutants by depleting the kinetochore component *hcp-4*. Rescuing spindle length in *tpxl-1* mutants did not rescue the defects in aster-based suppression, suggesting that TPXL-1 has a direct role in this process. We are currently testing whether aster-based clearing of contractile ring proteins depends on the ability of TPXL-1 to activate aurora A kinase. In summary, we identified the first molecular component of the aster-based mechanism that supports contractile ring assembly by inhibiting the accumulation of contractile ring proteins at the cell poles.

W4040A *t3421,* a novel mutation required for bipolar spindle assembly in the one-cell stage *C. elegans* embryo. *T. Mikeladze-Dvali*[1], A. C. Erpf[1], N. Memar[1], R. Schnabel[2]. 1) Biocenter, Ludwig-Maximilians-University, Munich, Germany; 2) Technical University Braunschweig, Braunschweig, Germany.

Centrosomes, the primary microtubule organizing centers (MTOC) of animal cells, consist of a pair of centrioles surrounded by pericentriolar-material (PCM). As in many metazoans, in the nematode *C. elegans*, the sperm contributes the sole centriole pair to the zygote at fertilization, whereas the centrioles of the oocyte are eliminated during oogenesis. Upon fertilization, paternally derived centrioles disengage, duplicate and mature to centrosomes. During the process of maturation centrioles recruit maternal PCM proteins and assemble the centrosomes, which in turn are required for the formation of a bipolar spindle and faithful chromosome segregation. Our overall objective is to uncover molecular mechanisms that regulate maternal centrioles during oogenesis and to understand how paternally derived centrioles orchestrate bipolar spindle formation.

Among a set of temperature-sensitive embryonic lethal mutations, we identified the mutant allele *t3421,* which causes defective spindle assembly in early embryos. Live imaging of embryos at a restrictive temperature, revealed the formation of monopolar spindles during the first cell cycle, followed by an abnormal cytokinesis, as well as tri- or tetrapolar divisions in the second cell cycle. Our preliminary results suggest that one of the two paternally contributed centrioles is defective in the process of PCM assembly during the first mitosis, indicating a failure in centrosome maturation. Since only one of the centrioles fails to assemble a functional aster, we speculate that the affected centriole is the younger one of two paternally contributed centrioles.

Currently we are conducting experiments to further explore the molecular nature of the mutation and to gain a better understanding of the phenotype. So far the mutation has been mapped to a region on Chromosome I that among others includes a nonsense mutation in an unknown coiled-coiled domain protein.

We expect that the detailed analysis of *t3421*will provide key insights into the mechanisms of maturation of the paternally contributed centrioles.

W4041B Polo-like kinase 1 is required for nuclear envelope breakdown and parental chromosome mixing during Caenorhabditis elegans early embryonic divisions. *M. M. Rahman*, O. Cohen-Fix. NIDDK at the National Institutes of Health, Bethesda, MD.

Mitosis is a highly regulated process that facilitates faithful segregation of genetic material into daughter cells. During mitosis in animal cells, nuclear envelope breakdown (NEBD) allows microtubules emanating from cytoplasmic centrosomes to connect to the duplicated chromosomes. The nuclear envelope (NE) reforms at the end of mitosis, generating a single nucleus in each daughter cell. NEBD following fertilization in a 1-cell embryo is poorly understood, especially in mammals where visualizing this process is challenging. It is assumed that once the maternal and paternal nuclei are in close apposition NEBD is initiated. The signals that promote timely NEBD are unknown. To visualize

mitotic events following fertilization we utilized early-stage embryos from *Caenorhabditis elegans.* Polo-like kinase 1 (Plk1) is a conserved kinase involved in multiple steps of mitosis. While Plk1 function is studied extensively in somatic cells, little is known about its function during embryonic development. We observed that in *C. elegans* embryo, growth of a temperature sensitive *plk-1* mutant (*plk-1*^{ts}) at the semi-permissive temperature led to the formation of two nuclei per cell, containing either the maternal or paternal DNA. This paired-nuclei phenotype was caused by a defect in NEBD, and specifically the formation of a gap in the NE at the interface between the maternal and paternal pronuclei during the first mitosis. In the *plk-1*^{ts} mutant we also observed a defect in chromosome alignment of the maternal and paternal metaphase plates relative to each other. Since PLK-1 is known to associate with chromosomes, the NEBD defect in a *plk-1*^{ts} mutant could be due to a direct requirement for PLK-1 at the NE region where the membrane gap is formed. We hypothesize that chromosome alignment may be necessary to achieve a critical concentration of chromosome-bound PLK-1 at the site of the future membrane gap. Alternatively, the NEBD in the *plk-1*^{ts} mutant could be due to an indirect requirement for PLK-1 in chromosome alignment, which in turn leads to a signal of an unknown nature that is necessary for gap formation in NE. Either way, PLK-1- dependent gap formation in the NE is essential for parental chromosome mixing. To further understand this process, we utilized data from a RNAi screen where we down regulated ~2000 genes critical for embryogenesis, and recorded changes in nuclear morphology in embryonic cells. To date, we have identified 17 candidates that, when down regulated result in paired nuclei formation. We are now investigating how inactivation of these gene functions leads to paired nuclei formation, and whether there's any functional relationship between these genes and the PLK-1 mediated NEBD regulation pathway.

W4042C Microtubule glutamylation is dispensable for *C. elegans* viability. *Katherine Badecker*, Jessica Lee, Ruchi Shah, Daniel Chawla, Megan Brewster, Zachary Barth, Nina Peel. The College of New Jersey, Ewing, NJ.

Glutamylation, the covalent attachment of glutamic acid to tubulin in the polymerized microtubule, is enriched on long-lived microtubules, and is proposed to contribute to centriole stability, cilia motility and axon function. Glutamylation of the microtubules is catalysed by a family of tubulin tyrosine ligase like (TTLL) enzymes. Comprehensive in vivo analyses of the function of tubulin glutamylation have proved challenging because of the existence of a large family of TTLL enzymes in many species. To investigate the function of tubulin glutamylation we have generated a *ttll-4(tm3310)*; *ttll-11(tm4059); ttll-15(tm3871) ttll-5(tm3360) ttll-9(tm3889)* quint mutant that lacks all five *C. elegans* glutamylating TTLL enzymes. The quint mutant shows normal embryonic viability and brood size indicating that the centrioles are functional and the microtubules of the spindle are competent for cell division. Recent evidence suggests that in human cells glutamylation modulates microtubule severing by spastin and katanin. To investigating whether a similar regulatory mechanism also exists in worms we have combined our quint mutant with mei-1(GOF) and mei-1(LOF) alleles of katanin. We do not however observe any suppression of the mei-1-associated lethality when microtubule glutamylation is lost. Our data therefore suggest that, contrary to expectations, microtubule glutamylation is not essential for *C. elegans* viability, although we do observe a male mating defect indicative of ciliary dysfunction. We are currently undertaking a detailed analysis of microtubule dynamics to determine whether minor perturbations of microtubule function occur in the absence of glutamylation.

W4043A The Power of One: A single wild type chromosome pair promotes chromosome partition in the first spermatocyte division of meiotic mutants. *Katherine A. Rivera Gomez*[1], Gunar Fabig[2], Thomas Muller-Reichert[2], Anne Villeneuve[3], Mara Schvarzstein[1]. 1) Brooklyn College, Brooklyn, NY; 2) Dresden University of Technology, Dresden, Germany; 3) Stanford University, Stanford, CA.

Errors in chromosome partitioning during meiosis result in aneuploid gametes that form embryos that die, arrest in development or have developmental abnormalities. Most of meiosis is devoted to temporarily connecting each maternally-derived homologous chromosome to its paternally-derived counterpart. These connections are generated by crossover recombination and are key in enabling the ordered partitioning the genome in the two meiotic divisions. In the first division, the connected homologous chromosomes are partitioned while keeping sister chromatids together in each homolog until the second nuclear division. The REC-8 cohesin is required for sister chromatids to segregate together to the same spindle pole in this division. Mutants that fail to form crossovers result in separate maternally- and paternally-derived homologous chromosomes. Observations by Severson *et al.* (2009) suggest that meiotic mutants that do not undergo crossover recombination segregate the homologous chromosomes in one of two ways in the first meiotic division of oocytes. In meiotic mutants that have REC-8, sister chromatids co-orient and each homologous chromosome segregates randomly. In meiotic mutants that lack REC-8, sister chromatids bi-orient and segregate away from each other in the first meiotic division. We will report our observations of chromosome partitioning defects in spermatocytes of meiotic mutants. Unlike mutants lacking REC-8, meiotic mutants defective in different steps leading to crossover recombination including; *him-3, syp-1, syp-2* and *spo-11*, fail to partition their chromosomes in the first division. These mutants still progress into the second meiotic division and form multipolar or connected spindles with bi-oriented sister chromatids that segregate to form four mostly aneuploid spermatids. Interestingly, analysis of *spo-11* mutant spermatocytes suggests that a single bi-oriented homologous chromosome pair is sufficient to suppress the formation of abnormal spindle organization in these mutants. The SPO-11 protein makes the double strand DNA breaks required for the initiation of crossover recombination. *spo-11* mutants can be rescued by inducing exogenously the formation of double strand DNA breaks. Induction of a single double strand break per nucleus generates one homologous chromosome pair. The formation of a single homologous chromosomes pair is sufficient to suppress the abnormal spindle organization seen in these mutant spermatocytes. We are currently investigating the cellular mechanism by which a single homologous chromosome pair might promote normal bi-polar spindle organization and segregation of meiotic mutant chromosomes that otherwise would not be partitioned in the first division.

W4044B Asymmetric positioning of organelles during epithelial cell polarization. *James Brandt*, Greg Hermann. Lewis & Clark College, Portland, OR.

The intestinal cells of C. *elegans* display asymmetrical positioning of multiple organelles soon after they become polarized at the E16 stage. At

this point in intestinal development, early and late endosomes, nuclei, and lysosomes are positioned near the nascent apical membrane while yolk granules are positioned basally. Our group studies the formation and behavior of an intestinal cell-specific lysosome related organelle (LRO) called the gut granule. The asymmetric positioning of LROs can be essential for their function, for example in movement of lytic granules to the immunological synapse in cytotoxic T-cells. In wild-type embryos, gut granules are positioned basally and excluded from the apical domain, which is where the nucleus is located. In *unc-83(-)* mutants, which lack polarized nuclei, gut granules are located both apically and basally, indicating that the positioning of the nucleus excludes gut granules from the apical domain. We have found that defects in two genes encoding ATP binding cassette (ABC) transporters lead to the accumulation of gut granules near the apical membrane. In these mutants, nuclei are still positioned apically. It is possible that gut granules are mispolarized in the mutants due to taking on the identity of an apical organelle. Our colocalization analyses between gut granule markers and markers for apically polarized organelles, including early endosomes (RAB-5, FYVE::GFP), late endosomes (RAB-7), and lysosomes (LMP-1), suggest the identity of gut granules are unaltered in the mutants. The positioning of endolysosomes, nuclei, and yolk were not altered in the mutants indicating that the overall cytoplasmic polarity of intestinal cells is not reversed. Interestingly, mutations in *mrp-4*, another ABC transporter, suppress the asymmetrical polarization of gut granules in the mutants. We will present models for the function of these ABC transporters in gut granule positioning.

W4045C SLO BK K^+ channels couple gap junctions to inhibition of Ca^{2+} signaling in olfactory neuron diversification. *A. Alqadah*[1,4], Y. W. Hsieh[1,4], J. Schumacher[2], X. Wang[2], S. Merrill[3], G. Millington[2], B. Bayne[2], E. Jorgensen[3], C. F. Chuang[1]. 1) Department of Biological Sciences, University of Illinois at Chicago, Chicago, IL; 2) Cincinnati Children's Hospital Research Foundation, Cincinnati, OH; 3) HHMI, University of Utah, Salt Lake City, UT; 4) Equal Contribution.

The *C. elegans* AWC olfactory neuron pair communicates to specify asymmetric subtypes, AWC^{OFF} and AWC^{ON} across the left-right axis. Intercellular communication between AWC and other neurons in a transient NSY-5 gap junction network antagonizes voltage-activated Ca^{2+} channels, UNC-2 (CaV2) and EGL-19 (CaV1), in the AWC^{ON} cell, but how Ca^{2+} signaling is downregulated by NSY-5 is only partly understood. We show that voltage- and Ca^{2+} -activated SLO BK potassium channels mediate gap junction signaling to inhibit Ca^{2+} pathways for asymmetric AWC differentiation. Activation of vertebrate SLO-1 channels causes transient membrane hyperpolarization, making it an important negative feedback system for Ca^{2+} entry through voltage-activated Ca^{2+} channels. Consistent with the physiological roles of SLO-1, our genetic results suggest that *slo-1* acts downstream of *nsy-5* to inhibit Ca^{2+} channel-mediated signaling to specify AWC^{ON}. We also show for the first time that SLO-2 BK channels are important for AWC asymmetry and act redundantly with SLO-1 to inhibit Ca^{2+} signaling. *nsy-5*-dependent asymmetric expression of *slo-1* and *slo-2* in the AWC^{ON} neuron is necessary and sufficient for AWC asymmetry. SLO-1 and SLO-2 localize close to UNC-2 and EGL-19 in AWC, consistent with functional coupling between these channels in AWC asymmetry. Furthermore, *slo-1* and *slo-2* regulate the localization of synaptic markers in AWC neurons to control AWC asymmetry. We also identify the requirement of *bkip-1*, which encodes a previously identified auxiliary subunit of SLO-1, for *slo-1* and *slo-2* function in AWC asymmetry. Together, these results provide an unprecedented molecular link between gap junctions and Ca^{2+} pathways for terminal differentiation of olfactory neurons. To identify the genes required for *slo-1* function in inhibiting Ca^{2+} signaling for promoting AWC^{ON}, we performed a non-biased forward genetic screen to isolate *mok* (modifier of K^+ channel) mutants that suppress the *slo-1(gf)* $2AWC^{ON}$ phenotype. From about 6000 genomes screened, we identified 16 new *mok* mutants that define genes required for *slo-1* function in promoting AWC^{ON}. We have identified the mutations responsible for these *mok* phenotypes using whole genome sequencing (kindly performed by Oliver Hobert's group). Molecular characterization of these *mok* genes will provide insight into how K^+ channels and Ca^{2+} channels may interact to coordinate stochastic AWC asymmetry.

W4046A Identifying factors that interact with PAX-3, a Paired-box protein involved in hypodermal cell fate specification in C. elegans. *M. CORREA-MENDEZ*[1], K. W. Thompson[1], P. Joshi[1], C. Y. Kang[1], J. Dymond[1], H. Smith[2], M. Krause[2], D. M. Eisenmann[1]. 1) University of Maryland Baltimore County, Baltimore, MD; 2) National Institutes of Health, Bethesda, MD.

The development of the *C. elegans* hypodermis is an excellent model for understanding cell fate specification and differentiation. Early events in *C.elegans* embryogenesis induce hypodermal precursor cells to adopt one of several fates among them, becoming dorsal, lateral or ventral hypodermal cells. The regulatory network that drives hypodermal cell fate specification is an intriguing process that still has much to be understood. While several transcription factors that function in specifying the major hypodermal cell fates have been identified, little is known about how the ventral and the lateral hypodermal cells are specified to adopt different fates and undergo distinct morphogenetic processes. Our findings begin to address how the ventral hypodermis is prevented from adopting a seam cell fate. Previously, we showed by mapping experiments and whole genome sequencing that *pvl-4* is the Paired-box gene *pax-3*, which encodes the sole PAX-3 transcription factor homolog in *C. elegans*. We (and others) report that *pax-3* is expressed in the ventral P cells during embryogenesis and early larval stages. Mutants for *pax-3*show embryonic and larval lethality as well as several body morphology defects that indicate abnormal cell fate specification in the hypodermis. Using several reporter genes we observed that in *pax-3* reduction-of-function animals the ventral P cells appear to undergo a cell fate transformation and adopt a lateral seam cell-like fate. Furthermore, forced expression of *pax-3* in the seam cells caused them to lose expression of seam cell markers. Based on these findings, we propose that *pax-3* functions in the embryonic ventral hypodermal cells to repress the lateral seam cell fate. *pax-3* promoter deletion analysis identified a *cis*-regulatory element that is necessary for *pax-3*expression in the embryonic P cells. Our current aim is to identify factors that regulate *pax-3* expression and that may function with *pax-3* in ventral cell fate specification. To do so, we used the Yeast One-Hybrid (Y1H) method to screen for factors that bind the *pax-3 cis*-regulatory element. Potential candidates are currently being analyzed.

W4047B Forward genetic screens for TLD mutants with defective localization of the TIR-1 Ca^{2+} signaling scaffold protein in left-right neuronal asymmetry. *Y.-W. Hsieh*, C.-F. Chuang. Department of Biological Sciences, University of Illinois Chicago, Chicago, IL.

The *C. elegans* left and right AWC olfactory neurons display stochastic asymmetry: one AWC subtype adopts the default AWC^{OFF} identity and the contralateral neuron is specified as the induced AWC^{ON} subtype. We previously showed that the TIR-1 (Sarm1) scaffold protein assembles a Ca^{2+}-regulated signaling complex at synaptic regions in the AWC axons, in a microtubule-dependent mechanism, to specify AWC^{OFF}. We also showed that proper localization of the TIR-1 Ca^{2+} signaling complex at the AWC synapses is important for precise AWC asymmetry.

To identify additional molecules required for the localization of TIR-1 in AWC subtype choice, we performed unbiased forward genetic screens to identify mutants with defective TIR-1 localization and AWC diversity. We screened through 8,560 genomes and identified six TIR-1 localization defective (*tld*) mutants with reduced localization of TIR-1 at synapses in the AWC axons, and/or accumulation of TIR-1 in the AWC cell body. Most of the *tld* mutants alone do not show a defect in AWC asymmetry. However, some *tld* mutants enhance the *tir-1(ky388)* reduction of function $2AWC^{ON}$ phenotype, supporting an important role of these *tld* genes in regulating TIR-1 trafficking and /or stability to specify AWC^{OFF}. We have identified the mutations responsible for the *tld* mutant phenotypes using whole genome sequencing (kindly performed by Alexander Boyanov in Oliver Hober's lab). Our study of the *tld* genes will provide insights into how cell-specific Ca^{2+} signaling proteins such as TIR-1 are linked to the conserved synaptic assembly in neuronal diversification. In addition to neuronal diversification, TIR-1 (Sarm1) is also implicated in innate immunity and axon degeneration. Identification and characterization of the genes, such as *tld*, that interact with *tir-1* in AWC asymmetry may advance our understanding of how TIR-1 (Sarm1) functions in other biological contexts including innate immunity and axon degeneration.

W4048C Investigation into the Regulatory Dynamics of LIN-1 and LIN-31, Transcription Factors Involved in *C. elegans* Cell Fate Specification. *R. Kousnetsov*, A. Dewey, L. Miller. Santa Clara University, Santa Clara, CA.

The Hox gene *lin-39* may play a role in initiating the 1° cell fate during vulval development in *C. elegans*. This cell fate specification process is triggered by a Ras/MAPK signal transduction cascade, wherein the transcription factors LIN-1 and LIN-31 are activated in order to upregulate expression of *lin-39*. However, the mechanistic details behind LIN-1 and LIN-31 regulation are not fully understood. Prior to activation, LIN-1 is SUMOlyated and serves as a transcriptional repressor, while the post-translational and transcriptional states of LIN-31 are unknown. Phosphorylation appears to convert LIN-1 and LIN-31 into transcriptional activators. Preliminary evidence from an electrophoretic mobility shift assay (EMSA) may indicate that SUMOlyation represses LIN-31 DNA-binding activity. Moreover, structural analysis of LIN-31 may suggest that SUMO serves as a linker that mediates the formation of a heterodimer between LIN-1 and LIN-31. Altogether, these findings may imply that LIN-1 and LIN-31 are concurrently regulated in similar manners, such that SUMOlyation acts as an OFF switch and phosphorylation acts as an ON switch for transcriptional activity. A variety of molecular techniques will be used to elucidate the regulatory dynamics of LIN-1 and LIN-31. EMSA and ChIP-seq will be used to determine the precise binding site of LIN-1 and LIN-31 on the *lin-39* promoter as well as to test the heterodimerization between LIN-1 and LIN-31. Further experiments with the CRISPR/Cas9 genome editing system will query whether particular structural elements on each transcription factor are necessary for proper regulation of vulval development.

W4049A The histone chaperone RBA-1 is critical for *C. elegans* postembryonic mesoderm development. *Jun Liu*, Stephen Sammons, Kevin Sun, Herong Shi, Vikas Ghai, Alice Hamilton, (Jun Liu is presenting the work primarily carried out by Stephen Sammons, who has left the lab). Cornell University, Ithaca, NY.

We use the *C. elegans* postembryonic mesodermal lineage, the M lineage, as a model system to study mesodermal patterning and cell fate specification. The M lineage arises from a single pluripotent cell, the M mesoblast, during embryogenesis. During postembryonic development of a hermaphrodite animal, the M cell undergoes a series of cell divisions to first produce 18 cells: 14 striated bodywall muscles (BWMs), 2 non-muscle coelomocytes (CCs), and 2 sex myoblasts (SMs), which further divide to produce the egg-laying vulval and uterine muscles (VMs and UMs). We and others have previously identified a number of transcription factors important for the proper patterning and fate specification in this lineage. In order to identify additional transcription factors that play a role in the M lineage, we used RNAi feeding and screened through over 500 putative chromatin-associated factors for their role in the M lineage using cell-type specific GFP reporters. One of the factors identified from the screen is the histone chaperone RBA-1. Both *rba-1(RNAi)* and *rba-1(0)* null mutants exhibit an extra VM phenotype. These extra VMs appear to arise from the fate transformation of M-derived CCs and BWMs to the VM precursors, the SMs. We have found that this M lineage defect is specific to *rba-1* loss-of-function, because a null mutation in the *rba-1* paralog *lin-53* did not cause any M lineage defects, and forced expression of *lin-53* failed to rescue the M lineage phenotype of *rba-1(0)* mutants. We are currently determining whether RBA-1 exerts its function by working with specific transcription factors important in CC and BWM fate specification in the M lineage.

W4050B SWI/SNF chromatin remodeling complexes interact with *hnd-1* and *let-381* to regulate the SGP/hmc cell fate decision. *L. D. Mathies*[1,2], D. M. Klompstra[2,3], E. E. Large[2,4]. 1) Virginia Commonwealth University, Richmond, VA; 2) North Carolina State University, Raleigh, NC; 3) NYU School of Medicine, New York, NY; 4) University of Missouri, Columbia, MO.

The two somatic gonadal progenitors (SGPs) of *Caenorhabditis elegans* are multipotent progenitor cells that give rise to all somatic tissues of the reproductive system, including uterus, sheath, spermatheca, distal tip cells and the anchor cell. Their sister cells are head mesodermal cells (hmcs), one undergoes programmed cell death and the other terminally differentiates shortly after it is born. We use this cell fate decision – SGP versus hmc – as a simple and genetically tractable model to understand the determinants of multipotency. Forward and reverse genetic approaches have identified *hnd-1/*dHand, *let-381/*FoxF and three different subunits of the SWI/SNF chromatin remodeling complex (*swsn-1, swsn-4,* and *pbrm-1*) as regulators of the SGP/hmc cell fate decision. Loss-of-function mutants in any of these genes have fewer than the normal number of SGPs and when the SGPs are present, they often express a marker that is characteristic of the hmc, suggesting that mutant

SGPs are partially transformed into hmcs. We examined *hnd-1; pbrm-1* double mutants and found that they have a synergistic phenotype, indicating that *hnd-1* and SWI/SNF act in parallel. We also found that *let-381* is co-expressed with *hnd-1* in the SGPs and *hnd-1* promoter deletions that remove three predicted LET-381 binding sites abolish expression of a rescuing *hnd-1::GFP* reporter in SGPs. Taken together, our data support a model in which *let-381* acts upstream of *hnd-1* and the SWI/SNF complex acts in parallel to *hnd-1* to regulate gene expression in SGPs. HND-1 is a transcription factor and SWI/SNF chromatin remodeling complexes influence gene expression by altering chromatin structure. Therefore, a simple model is that SWI/SNF acts by facilitating the binding of HND-1 to its target genes to regulate gene expression in SGPs. SWI/SNF chromatin remodeling complexes are important for the proliferation of mammalian multipotent progenitors. The identification of downstream targets of SWI/SNF in the SGP/hmc cell fate decision may therefore uncover conserved molecular mechanisms regulating multipotency in diverse species.

W4051C Genetic Control of the Maintenance of the AIA Cell Fate. *Josh Saul*, Takashi Hirose, Bob Horvitz. HHMI, MIT, Cambridge, MA.

Cell fate can be considered to involve two steps: establishment, in which an undifferentiated cell commits to a final, differentiated fate; and maintenance, in which a differentiated cell preserves the expression of its fate while precluding others. Cell-fate establishment has been well studied and is characterized by changes in cell morphology, gene expression and cellular function. Cell-fate maintenance has received comparatively little attention, and the mechanisms by which cell fate is maintained are poorly understood.

From a screen for *C. elegans* genes that specify cells for programmed cell death, we identified a gene, *ctbp-1*, that instead appears to be involved in maintaining one or more cell fates. *ctbp-1* encodes the worm homolog of the CtBP family of proteins, which in mice have been shown to act as transcriptional co-repressors that regulate gene expression during embryonic development. *ctbp-1* loss-of-function adult animals show ectopic gene expression in the AIA neurons, whereas L1 *ctbp-1* animals do not display this abnormality. Furthermore, adult but not L1 *ctbp-1* animals are defective in a turning behavior mediated by the AIAs. These observations indicate that AIA is normal in L1 but abnormal in adult animals, consistent with the hypothesis that *ctbp-1* mutants properly establish the AIA cell-fate establishment but fail to maintain this fate later.

We are currently attempting to test this hypothesis and to determine the mechanism by which *ctbp-1* might regulate cell-fate maintenance. We have performed a mutagenesis screen for suppressors of the misexpression phenotype of *ctbp-1* mutants to identify genetic interacting partners of *ctbp-1* and have identified 21 independent isolates that we are currently mapping. We have also performed RNA-seq to identify other genes misexpressed in *ctbp-1* mutants.

We hope to develop an understanding of the genetic control of cell-fate maintenance by specifically investigating how CTBP-1 promotes the maintenance of the AIA fate. This work might provide insight into diseases, such as cancer, in which perturbation of the maintenance of tumor cell fate might intervene with the oncogenic process.

W4052A Dissecting the roles of the zinc finger transcription factor SEM-4/SALL in distinct cell fate specification programs in the *C. elegans* postembryonic mesoderm. *Qinfang Shen*, Vikas Ghai, Chenxi Tian, Herong Shi, Jun Liu. Cornell University, Ithaca, NY.

We are interested in dissecting the regulatory network underlying the generation of multiple distinct cell types from a single pluripotent precursor cell. We are using the *C. elegans* postembryonic mesodermal lineage, the M lineage, as a model system. The M lineage is derived from a single pluripotent cell, the M mesoblast. During hermaphrodite postembryonic development, the M cell divides to produce fourteen striated body wall muscles (BWMs), two non-muscle coelomocytes (CCs), and two sex myoblasts (SMs) that are precursors of the sixteen non-striated egg-laying muscles. Mutations in the zinc finger transcription factor SEM-4/SALL lead to the transformation of M-derived CCs and SMs to BWMs (Basson and Hortitz, 1996). We have found that *sem-4* is expressed throughout the M lineage, and that overexpression of *sem-4* in the M lineage can lead to the fate transformation of CCs to SMs. These results indicate that SEM-4 is both necessary and sufficient to specify the SM fate, while the level of SEM-4 is critical for proper specification of M-derived CCs. The role of SEM-4 in SM specification appears to be mediated by the SoxC protein SEM-2, which is required and sufficient for SM fate specification (Tian et al., 2011): SEM-4 is required for *sem-2* expression in the SM mother and SM cells, and SEM-2 is required for *sem-4*-induced SM formation.

The SEM-4 protein contains seven zinc finger motifs of the C2H2 class. We have found that different *sem-4* alleles that affect different zinc finger motifs exhibit different effect on CC vs. SM fate specification. These observations suggest that the distinct zinc finger motifs in SEM-4 mediate distinct functions, either having different DNA binding activities or via interacting with different co-factors, or both. Current research aims at distinguishing between these different possibilities.

W4053B Identification of a novel Ral signal transduction cascade in *C. elegans* 2˚ vulval fate patterning. *Hanna Shin*[1], Rebecca E. W. Kaplan[2], Channing J. Der[2], David J. Reiner[1,2]. 1) Institute of Biosciences and Technology, Texas A&M Health Science Center, Houston, TX, USA; 2) Department of Pharmacology and Lineberger Cancer Center, University of North Carolina, Chapel Hill, NC, USA.

Vulval precursor cells (VPCs) are patterned through graded action of EGF from the anchor cell (AC) in conjunction with LIN-12/Notch-mediated lateral signaling. Together these signals control the highly reproducible 3˚-3˚-2˚-1˚-2˚-3˚ pattern that develops to form the vulva. A key protein in this process is LET-60/Ras, which in mammals is the most mutated oncoprotein. EGFR promotes LET-60/Ras activation to induce 1˚ fate via the canonical Raf-MEK-ERK MAP kinase cascade. We previously demonstrated that LET-60/Ras also switches effectors to activate its

effector RalGEF-Ral to induce 2˚ fate in support of Notch. In general, 1˚- and 2˚-promoting signals are strongly antagonistic. Thus, in equipotent cells Ras switches effectors between Raf and RalGEF-Ral to promote mutually antagonistic 1˚ and 2˚ cell fates, respectively. However, the Ral signaling cascade is poorly understood in all systems. We therefore screened candidate Ral binding partners from the literature. Two subunits of the Exocyst complex have been previously shown to bind Ral in other systems. We found that loss of Exo84 but not Sec5 caused the same phenotype as loss of Ral, suggesting that Ral binds to Exo84 to promote 2˚ fate. To move further downstream we analyzed a little known family of MAP4 kinases. In *Drosophila* Sec5 and Msn/MAP4K, the ortholog of *C. elegans* MIG-15, physically interact and promote JNK signaling, but function in opposition to Ral signaling. Consistent with the *Drosophila* genetics, our preliminary data in vulval development do not support the model that Sec5 and Msn function as a Ral effector. We hypothesize that the paralogous MAP4K subfamily, *C. elegans* GCK-2 and *Drosophila* Hppy, constitutes the real Ral effector. We found loss of GCK-2 phenocopies loss of Exo84, and GCK-2 functions cell autonomously downstream of Ral in vulva. Activated small GTPases often recruit effectors to membranes. Using CRISPR/Cas9, we tagged the N-terminus of endogenous GCK-2 with mNeonGreen. mNG::GCK-2 is localized in the cytoplasm of 1˚ and 2˚ cells, with perinuclear concentration. Thus, the mechanism by which Ral and Exo84 activate GCK-2 remains unclear. We will tag endogenous Ral with TagRFP to assess co-localization of mNG::GCK-2 and TagRFP::Ral in 1˚ vs. 2˚ before and after EGF induction. We also found that Ral-Exo84-GCK-2 signals through a conserved MAP3K/MLK-1-MAP2K/MEK-1-p38/PMK-1 cascade. This cascade may further activate MAPKAP kinase, MAK-2. We will generate p38::mNeonGreen to measure the activity of Ral signaling cascade through activation-dependent cytoplasmic-to-nuclear translocation of p38.

W4054C BAR-1 and CCAR-1 cooperate to properly position a subset of motor neurons along the AP axis. *Jeffrey Hung*[1,2], Matt Tanner[1,2], Antonio Colavita[2]. 1) University of Ottawa, Ottawa, Ontario, Canada; 2) OHRI, Ottawa, Ontario, Canada.

There are three classes of embryonically derived motor neurons (DD, DA and DB) that are organized into a very stereotypical pattern along the ventral nerve cord (VNC). For example, the six DD neurons (DD1-6) are evenly spaced along the AP axis and each are invariably situated between the same DA or DB neighbour. The planar cell polarity pathway (PCP) is a non-canonical Wnt pathway involved in establishing cell and tissue polarity. Recently we discovered that disruption of a PCP like pathway that includes highly conserved genes such as vang-1/Van Gogh and prkl-1/Prickle result in DD, DA and DB spacing defects. Imaging of comma to 1.5 fold stage embryos revealed that these defects are caused by delays in the cell intercalations that ultimately generates the linear profile of motor neurons along the ventral nerve cord. To identify new genes involved in motor neuron positioning or tiling we examined other conserved components of canonical and non-canonical Wnt pathways for DD position defects. We found that mutations in bar-1/beta-catenin displayed a highly penetrant phenotype in which DD1 and DD2 are clustered together at all larval stages instead of being properly spaced/tiled in the VNC. We found the same phenotype, although somewhat milder, in ccar-1/cell division cycle and apoptosis regulator-like-1 mutants. CCAR1 is a transcriptional regulator that in vertebrates has been shown to physically interact with beta-catenin to control the expression of Wnt regulated genes. In bar-1 and ccar-1 mutants DD2 is displaced anteriorly closer to DD1. PRY-1/Axin is a negative regulator of the Wnt signalling pathway as a part of a destruction complex involved in degrading BAR-1/β-catenin. Interestingly, pry-1 mutants also have a DD1-DD2 spacing defect but one in which DD1 is displaced posteriorly closer to DD2. In all three mutants, the spacing of the other DD neurons (DD3-6) are not strongly affected. These findings suggest that a non-canonical Wnt pathway may be involved in properly separating DD1 and DD2 during VNC formation or elongation of the embryo.

W4055A Centrosome-cortical contact duration affects anterior-posterior polarity in the one-cell *C. elegans* embryo. *D. M. Saturno*, D. Stephens, D. Parikh, E. Jaeger, R. Lyczak. Ursinus College, Collegeville, PA.

Anterior-posterior axis establishment occurs in the one-cell *C. elegans* embryo, triggered by the sperm-donated centrosome. While it is believed that the centrosome can cue polarity from a distance, centrosomes are pushed to contact the cortex during the polarization process. The role for this sustained cortical contact remains an open question. Centrosomes are mislocalized in one-cell *pam-1* embryos and polarity establishment fails. This phenotype is rescued however, when centrosomes are made to contact the cortex by inactivating dynein heavy chain. To examine in detail the requirement for centrosome-cortical contact, we used time-lapse confocal imaging of wild-type and *pam-1* mutant strains with GFP-tagged centrosome and PAR polarity proteins. We measured timing and duration of contact, as well as centrosome distance from the cortex and correlated these centrosome dynamics with the timing of symmetry breaking and PAR protein localization. We discovered that *pam-1* embryos had comparable centrosome-cortical distances from wild-type, but exhibited shorter centrosome-cortex durations. Very short durations in *pam-1* correlated with a delay in or lack of symmetry breaking in embryos. In addition, while centrosome distance from the cortex did not affect the extent of PAR localization, we found that duration of centrosome contact made a difference in *pam-1* mutants. Shorter duration times correlated with smaller PAR-1 posterior domains. Taken together, these results suggest that centrosome contact is required for robust polarization when *pam-1* is absent.

W4056B Suppressor screening to identify new regulators of anterior-posterior axis establishment in *Caenorhabditis elegans*. *E.Mae. Schleicher*[1], R. Alsher[1], T. Litz[1], A. Kilner[1], A. Kimble[1], K. Power[1], E. Jaeger[1], J. Lowry[2], B. Bowerman[2], R. Lyczak[1]. 1) Ursinus College, Collegeville, PA; 2) University of Oregon, Eugene, OR.

Polarity is established in the one-cell *C. elegans* embryo shortly after fertilization and determines the anterior-posterior body axis. This polarization is cued by the sperm-donated centrosome, which triggers changes in the posterior cortex. It is not well understood how the centrosome is positioned in the early embryo to trigger this polarization. Our previous work uncovered a role for the PAM-1 aminopeptidase in positioning the centrosome at the cortex to allow for proper axis polarization. PAM-1 is a highly conserved aminopeptidase that targets unknown proteins for degradation. In the absence of functional PAM-1, centrosomes are mispositioned and the anterior-posterior axis fails to establish correctly. In order to identify novel regulators of centrosome positioning and targets of the PAM-1 aminopeptidase, we took advantage of the maternal-effect embryonic-lethal phenotype of *pam-1* mutants to conduct a suppressor screen. We have identified six

suppressors, which significantly increase the *pam-1* hatch rates from 2% to between 25-96%. Two of these suppressors are dominant while the others are recessive. Using DIC microscopy we have found that each suppressor significantly rescues the polarity defects, such as the lack of pseudocleavage and the symmetric cleavage, found in *pam-1* mutants. We have also discovered that some, but not all, of our suppressors can rescue more than *pam-1* allele, pointing to different mechanisms of action. We are currently mapping the suppressor mutations to identify the molecular identity. Toward this end, we have used whole genome sequencing on two of our suppressors and are currently verifying the lesions to identify the suppressors in these strains. Future characterization of these suppressors is likely to uncover new insights into the role of this aminopeptidase in centrosome positioning and polarity establishment.

W4057C Development of Quantitative Imaging Toolkit to Monitor the Process of Symmetry Breaking. *P. ZHAO*[1,2], Z. ZHANG[2,3], H. T. ONG[2,3], T. KANCHANAWONG[2,3], F. MOTEGI[1,2,3]. 1) Temasek Life Sciences Laboratory, Singapore; 2) National University of Singapore, Singapore; 3) Mechanobiology Institute, Singapore.

Caenorhabditis elegans early zygote undergoes de novo polarization upon fertilization. Previous studies have shown that maturing centrosomes could break symmetry by destabilizing contractile network of actomyosin, leading to segregate PAR-type polarity regulators along the anterior-posterior axis. Centrosome maturation-defective mutants, however, can break symmetry during the later stage of first mitosis, and occasionally formed two posterior domains. To assess how singularity can be established and/or violated under the compromised centrosomes, we developed quantitative image-analysis tools to monitor subtle changes of cortical actomyosin and PAR proteins in response to centrosome movement with high temporal and spatial resolution. We observed in different mutant embryos that early zygote retains the competency to break symmetry throughout the first cycle, during meiotic to mitotic transition, upon mitotic entry, and even during cytokinesis. The quantitative imaging also observed roles of several mitotic kinases in global control of cortical actomyosin dynamics. We will discuss a progress of our quantitative screening to identify genes essential for cortical symmetry breaking in early zygotes.

W4058A Developmental and cancer cell invasion share regulatory pathway components. *Evelyn Lattmann*[1,2], Ting Deng[1], Charlotte Lambert[1], Michael Daube[1], Valerie Amann[2], Ines Kleiber-Schaaf[2], Mitch Levesque[2], Reinhard Dummer[2], Alex Hajnal[1]. 1) University of Zurich, Zurich, CH; 2) University of Zurich Hospital, Zurich, CH.

A critical step in metastasis formation by invasive tumor cells is the breaching of the basement membrane (BM), which is a natural barrier that separates sheets of cells. Besides its involvement in disease, BM breaching is essential for proper organ formation during normal development. Recent studies provide evidence that there are parallels between developmental and tumor cell invasion. One well-studied developmental invasion process is anchor cell invasion in *Caenorhabditis elegans*, where a specialized cell (anchor cell) in the uterus invades into the adjacent vulval epidermis. Because anchor cell invasion can easily be manipulated and observed, we use this system as a functional assay to characterize the *C. elegans* homologues of human genes, which are upregulated in invasive melanoma cells and during neural crest cell migration. From an initial list of 112 invasion-associated human genes we identified, through our functional *C. elegans* screen, 14 genes that showed an anchor cell invasion defect. Notably, three of the candidate genes encode cell cycle regulators and four genes are involved in protein sumoylation. Currently, the validated candidates are further studied using *in vitro* invasion assays with human melanoma cells and immunohistochemistry analysis of in situ and minimally invasive melanoma biopsies. Our long-term goal is to establish molecular markers of tumor invasiveness that may also be potential drug targets.

W4059B A promoter element in the *C. elegans nhr-67 tailless* gene mediates *hlh-2/daughterless* regulation of anchor cell differentiation and uterine organogenesis. *Caroline Berman*, Akshara Kartik, Sheila Clever, Bruce Wightman. Muhlenberg College, Allentown, PA.

The *tailless* family of nuclear receptors is highly conserved among animals. In humans, it functions in regulating neuronal stem cell differentiation. The *C. elegans tailless* ortholog, *nhr-67*, is expressed in a dynamic pattern in pre-uterine cells: initially in the 4 pre-VU cells during the L2, then upregulated in the anchor cell (AC) in response to the *lin-12/lag-2* Notch reciprocal signaling system. During the L3 stage, *nhr-67* expression is maintained at high levels in the AC and at low levels in VU descendants that produce the adult ventral uterus. *nhr-67* is required for expression of the *lin-12/Notch* receptor in pre-VU and VU cells and for multiple markers of AC identity, indicating that it functions in differentiation of both uterine cell types.

Deletion of a 276bp region of the *nhr-67* promoter results in a loss of *nhr-67* expression in pre-VU, AC, and VU cells. Expression of *276bp region::gfp* shows the region is necessary and sufficient for *nhr-67* expression during ventral uterine development. The region includes two E box sequences that we propose bind the HLH-2 transcription factor, which functions in AC and pre-VU development. We have performed site-directed mutagenesis to delete the E boxes and four other conserved elements from the 276bp promoter region and tested their functions directly *in vivo*. Our data demonstrate the primary role of the E box sequences in regulating *nhr-67* in the AC, pre-VU, and VU cells. *Funded by the NIGMS.*

W4060C The *fax-1* nuclear receptor of *C. elegans* functions in gonad development. *Sydney Saltzman*[1], Emily Bayer[1,2], Sheila Clever[1], Bruce Wightman[1]. 1) Muhlenberg College, Allentown, PA; 2) Columbia University, New York, NY.

The nuclear receptors constitute a class of conserved transcription factors that function in regulating animal development. The NR2E subclass nuclear receptor *fax-1* of *C. elegans* is expressed in hermaphrodite somatic gonad cells and is required for normal brood size, in addition to roles already described in neuron differentiation.

The *C. elegans fax-1* gene is the ortholog of PNR in vertebrates. We have found that *fax-1* is expressed in the migrating distal-tip cells (DTCs) of the hermaphrodite gonad from L2 through L4 stages. Loss of *fax-1* results in a low-penetrance DTC migration defect and a high penetrance brood size defect. The reduction in offspring appears to result from a defect in sperm production rather than oogenesis.

The letter preceding the number is the community. A, B, C after the number is presentation time.
W – *C. elegans*, C – Ciliates, D – Drosophila, M – Mouse, P – PEQG, Y – Yeast, Z – Zebrafish

The *vab-3* transcription factor plays a key role in regulating the migrations of the DTCs. In *vab-3* mutants, the DTCs continue to migrate into adulthood and also fail to turn off *fax-1*, suggesting that expression of *fax-1* is a property of a migrating DTC. A mutation in *fax-1* does not suppress the *vab-3* migration defect, indicating that *fax-1* is not an essential downstream mediator of *vab-3* function. We propose that *fax-1* function in DTC migration is a robustness phenomenon, in contrast to the more demanding requirement for hermaphrodite spermatogenesis. *Supported by NIGMS.*

W4061A The role of sumoylation in cell invasion. *A. Fergin*, E. R. Lattmann, C. A. Lambert, A. Hajnal. University of Zürich, Zürich, Switzerland.

Cell invasion plays crucial roles during normal development and in in many human diseases, especially in metastatic cancer. To date, the molecular mechanisms allowing cells to traverse through natural barriers like basement membranes (BM) remain poorly understood.

C. elegans is an excellent *in vivo* model to study cell invasion during normal development. During the L3 stage of hermaphrodite development, the specialized gonadal anchor cell (AC) breaches two BMs separating the gonad from the vulva precursor cells (VPCs). The AC then invades into the vulval epithelium to initiate vulval morphogenesis. Many genes regulating AC invasion as well as the structural components of the BM are highly conserved in *C. elegans*. Therefore AC invasion is a powerful model to study the first steps of tumor cell metastasis.

In order to identify novel regulators of anchor cell invasion, we performed a targeted RNAi screen and found that the components of the sumoylation pathway are important for AC invasion. By screening the genes encoding sumoylated proteins for a possible role during AC invasion, we identified *icd*-2 (inhibitor of cell death 2) and *iff*-2 (eukaryotic translation initiation factor 5A-2) as novel regulators of AC invasion. Both genes have orthologs in humans, contain classical and non-classical SUMO motifs and are essential for proper development. We are using a CRISPR/Cas9 approach to tag and further investigate the role of both of the identified proteins and sumoylation in cell invasion. Our results so far suggest that protein sumoylation is crucial for the AC invasion.

W4062B Study of antipsychotics-induced side effects in *C. elegans*. *M. Carretero*, V. Titova, R. Gomez-Amaro, M. Petrascheck. The Scripps Research Institute, La Jolla, CA.

Atypical, or second-generation, antipsychotics are the first line of defense in the treatment of schizophrenia and psychosis. One of the main side effects of treatment with antipsychotics is weight gain. Weight gain can lead to the development of a variety of conditions such as insulin resistance, diabetes, dyslipidemia, and increased cardiovascular risk. Over the past few years many studies have demonstrated that this weight gain is not only due to changes in metabolism but that treatment with antipsychotics can also induce hyperphagia through currently unknown molecular mechanisms. We developed a powerful microtiter-plate based system to measure food intake in *C. elegans* and have found that antipsychotics also induce hyperphagia in worms. The conservation of this phenotype allows us to take full advantage of the power of *C. elegans* as a model organism to study the genetics of antipsychotics-induced hyperphagia. We have used this system to analyze the signaling pathways involved in antipsychotics-induced hyperphagia, in addition to studying the effects on food intake in mutant *C. elegans* with defects in orthologues of human genes known to be affected in response to antipsychotics treatment.

W4063C Arecoline improves age-dependent motor functional decline and extends lifespan by activating GAR-2 receptor in motor neuron in *C. elegans*. *Yen-Chieh Chen*[1], Mu-Yun Tseng[2,3], Travis Mazer[4], Tsui-Ting Ching[1], Ao-Lin Hsu[2,3,4]. 1) Institute of Biopharmaceutical Sciences, National Yang-Ming University, Taipei, Taiwan; 2) Institute of Biochemistry and Molecular Biology, National Yang-Ming University, Taipei, Taiwan; 3) Program in Molecular Medicine, National Yang-Ming University and Academia Sinica, Taipei, Taiwan; 4) Department of Internal Medicine, Division of Geriatric and Palliative Medicine, University of Michigan, Ann Arbor, MI 48109, USA.

Aging is characterized by progressive decline in physiological functions with increasing chronological ages. Among all the age-dependent declines, loss of motor function represents one of the most prominent physiological declines in aging animals and humans. Our previous work has shown that motor neurons exhibit a progressive functional decline in the early life of *C. elegans*, while skeleton muscles remain functional until mid to late life. Here, we report that arecoline, a muscarinic acetylcholine receptor agonist can improve the age-dependent functional loss of the motor nervous system and significantly increase the lifespan of the animals. There are three different muscarinic acetylcholine receptors in worms, GAR-1, -2, -3. When we applied arecoline to these three muscarinic acetylcholine receptor mutants, we found that arecoline failed to extend only the lifespan of *gar-2* mutants, but not the other two. Therefore, this suggests that GAR-2 receptor, which is participated in the Gq signaling, might mediates the effect of arecoline on lifespan extension. Furthermore, *egl-8* (PLCβ), a downstream effector of Gq signals is also required for arecoline treatment to extend lifespan, suggesting that arecoline-induced lifespan extension may mediate through GAR-2/PLCβ pathway. Finally, we found that the over-expression of *gar-2* only in motor neuron is sufficient to rescue the arecoline-induced lifespan extension in *gar-2* mutants, suggesting that arecoline-induced lifespan extension acts specifically in motor neuron. Our findings have implicated a potential way to mitigate the age-dependent decline in motor activity. Further investigating the mechanism of action may eventually lead to the development of interventions that can increase both the heath span and the lifespan of humans.

W4064A S-adenosylmethionine synthetase-5, SAMS-5, in the regulation of longevity in *C. elegans*. *T. Ching*, C. Chen. National Yang-Ming University, Taipei, TW.

Previous studies have shown that S-adenosylmethionine synthetase-1 (SAMS-1) might be involved in the lifespan extension induced by dietary restriction (DR). In *C. elegans*, there are five S-adenosylmethionine synthetases, SAMS-1, SAMS-2, SAMS-3, SAMS-4, and SAMS-5. However, little is known with regard to the roles of other SAMs in the regulation of longevity. Through RNAi knockdown assays, we found that, like *sams-1*, inhibition of *sams-5* by RNAi or genetic deletion extends the lifespan of wildtype animals. Interestingly, unlike *sams-1* mutants,

sams-5 mutants does not exhibit the intestinal vacuoles accumulation phenotypes, which is a indication of defected lipid synthesis. The expression pattern of *sams-5* is also distinct from that of *sams-1*. In larvae stages, SAMS-5 is expressed in the intestine and a subset of neurons. However, the expression of SAMS-5 in the intestine is vanished in young adults. Genetic epistasis analysis suggests that *sams-5* is not required for the lifespan regulation of DR, in which *sams-1* plays an important role. Together, our studies suggest that *sams-5* might act through a different pathway from *sams-1* to modulate longevity.

W4065B Investigating the role of intestinal cell-to-cell communication in longevity in *C. elegans*. *C. Diehl*, K. Li, M. Peters. Oberlin College, Oberlin, OH.

In *C. elegans*, the intestine integrates nutrient uptake and systemic aging signaling. Low food or other stressors lead to the activation of key transcription factors, DAF-16 and SKN-1, initiating a set of adaptations resulting in decreased fecundity and increased lifespan. Recent research suggests that another feeding-induced intestinal process, the periodic calcium wave controlling the defecation cycle, is linked to aging and death. The terminal step of aging, death, is preceded by a fluorescent anthranilate wave (death wave) in the intestine (Coburn et al., 2012). We have investigated mechanisms underlying lifespan extension in an intestinal gap junction mutant, innexin (*inx-16),* that alters both the defecation calcium wave and the death wave.

In feeding animals, a rapid posterior to anterior calcium wave occurs synchronically with defecation. In the absence of functional *inx-16*, the intestinal calcium waves are markedly slower and sometimes fail entirely, causing serious defecation defects. Just prior to death, calcium levels rise in anterior intestinal cells leading to necrosis. The calcium and necrosis spread, producing the death wave. *inx-16* mutants do not produce these waves (Coburn et al., 2012).

inx-16 mutants exhibit increased lifespan compared to N2 which could be due to failed execution of the necrotic death wave. To determine whether adding functional intestinal INX-16 to adults could restore normal lifespan we performed an adult rescue of the mutant using a vitellogenin promoter. This adult intestinal rescue eliminated defecation defects but failed to normalize lifespan. This suggests that *inx-16's* extended lifespan is not due solely to a failure to die. We hypothesize that intestinal and/or nutrient deficiencies in early life induce a longevity program that cannot be altered later. We are investigating the nutritional state and the longevity molecular program in *inx-16* mutants. Feeding as measured by pharyngeal pumping rates appears normal. Activation of DAF-16 and/or SKN-1 is being assayed via analysis of nuclear localization in translational fusion lines. No significant increase in nuclear DAF-16 has been found in the mutants' intestines. Yolk protein production and oocyte uptake is also being scored as a downstream marker of DAF-16 and SKN-1 activation. Fluorescent imaging of vitellogenin::GFP fusions indicate defective yolk protein distribution in *inx-16* mutants and likely decreased production. This work will provide valuable insight into links between intestinal cell-cell communication, nutrient uptake and longevity.

Coburn C. et al. (2013) PloS Biology Jul;11(7):e1001613.

W4066C Bacillus subtilis and Caenorhabditis elegans are good friends. *V. Donato*, S. Cogliati, R. Grau. National University of Rosario. School of Biochemistry. CONICET. Microbiology Lab. Rosario, Santa Fe, Argentina.

It is believed that beneficial gut bacteria (probiotics) might positively contribute to the modulation of aging and the nervous system in their hosts. However, the mechanisms causing the effects due to probiotics remain poorly understood. In this way, the role of *in vivo* probiotic biofilm development during gut colonization and its effects on animal health and lifespan are poorly documented. For these reasons, we have investigated the ability of *B. subtilis,* a probiotic bacteria, to form a biofilm, to produce nitric oxide (NO) and to synthesize quorum sensing molecules in the *C. elegans* gut and we evaluated its effects on gut colonization, lifespan and in the modulation of the nervous system of *Caenorhabditis elegans*. The traslucent nematode *C. elegans* has proven to be an excellent model for the study of many central biological processes, including how the gut microbiota affects host physiology.The two wild-type *B. subtilis* strains used in this study were the domesticated and laboratory-reference strain JH642 and the isogenic undomesticated and wild *B. subtilis* strain NCIB3610. We also used mutant strains of this bacterium. N2 and mutant strains of *C. elegans* containing, as the food source, OP50 *E. coli* cells or *B. subtilis* as spores or vegetative cells or *P. aeruginosa* (PA14) were used in many essays. We developed lifespan experiments, thermotolerance and other stress essays. We cultured bacteria from worms, we studied biofilm development in the *C. elegans* gut, we used pulse-chase experiments to evaluate persistance and we measured NO and CFS under planktonic and biofilm conditions. Finally, we studied the intracellular routes that are involved in this bacteria-host interaction and the beneficial effects that this relationship produced in the nervous system of the host.Our work showed that *B. subtilis* spores are able to germinate, growth, make a biofilm, re-sporulate and persist in the intestine of *C. elegans*. Moreover, the proficiency of biofilm formation and the production of the anti-aging molecule NO and the quorum sensing pentapeptide CSF act separately to extend worm longevity. Furthermore, *B. subtilis* grown under biofilm-supporting conditions synthesizes higher levels of NO and CSF than under planktonic growth. We also could discover the routes involved in these effects and the property that this probiotic has to delay neurodegeneration produces by for example *P. aeruginosa* (PA14).In sum, *B. subtilis* can improve the health and lifespan of its host and its biofilm proficiency is a crucial factor.

W4067A Elucidating drivers of proteostasis decline by targeting age-related accumulation of insoluble protein. *Kathleen J. Dumas*, Niall Adams, Birgit Schilling, Ida Klang, Pedro Reis-Rodrigues, Karla Mark, Daniel Edgar, Dipa Bhaumik, Bradford W. Gibson, Gordon J. Lithgow. Buck Institute for Research on Aging, Novato, CA.

Defective protein homeostasis (proteostasis) is a key driver of many age-related diseases in humans and is recognized as a key element in normal aging. We developed a proteome-wide assay of proteostasis based on the accumulation of SDS-insoluble proteins during normal aging in *C. elegans,* utilizing mass spectrometry to identify specific insoluble proteins. We hypothesize that this accumulation of dysfunctional protein is a result of failure or decline in capacity of specific nodes in the proteostatic network. Comparison of multiple distinct proteome-wide

insoluble protein datasets yielded several hundred proteins which reproducibly appear in the insoluble fraction of old (aged to adult day 7 or greater) *C. elegans*. Analysis of these age-related insoluble proteins revealed significant enrichment for proteins involved in metabolism, protein folding, and translation. We have created transgenic animals expressing GFP tagged proteins from this set of reproducible age-related insoluble proteins, and are using these strains to investigate the drivers of proteostasis decline with age.

W4068B Investigation of medicinal and therapeutic effects of boronic acid compounds in an Alzheimer's Disease model of *Caenorhabditis elegans*. *D. Flaherty*, W. Lawless, L. Hall, A. McKelvy, D. Makholm, J. Larkin. Eckerd College, St. Petersburg, FL.

Alzheimer's Disease (AD) is a progressive neurodegenerative disease which affects an estimated 44 million people over the age of 65 (Alzheimer's Disease International). The aggregation of amyloid-β ($A\beta_{1-42}$) into "senile plaques" is a hallmark cellular pathology of the disease. Accumulation of $A\beta_{1-42}$ is a main target of therapeutic research due to the caustic and toxic nature of these aggregates. The *C.elegans* transgenic model GMC101 expresses full length human $A\beta_{1-42}$ in its body wall muscles, which aggregates and leads to permanent and severe paralysis, allowing for robust behavioral outcome to score for plaque burden. Similarly, strain CL2006 is an abundant expresser of Ab_{3-42} and provides a useful model for aggregate analysis.

Boronic acid compounds have been utilized in a wide range of drug therapies because of their high level of specificity and ability to interact with the proteasome. To date, these compounds have not been extensively studied in AD related pathology. We have hypothesized several potential benefits of boronic acid and boronic ester compounds to AD pathology, including enzyme inhibition and proteasome interaction. Our preliminary data indicate that boronic ester compounds have a major impact on the toxicity of $A\beta_{1-42}$ by significantly delaying paralysis in the GMC101 model. This result has been further supported via fluorescence microscopy with the use of the fibrillary stain Thioflavin T (ThT), which identified a substantial decrease in $A\beta_{1-42}$ aggregation compared to the controls. To further confirm our findings, we have also begun to conduct *in vivo* staining in live animals using the lipophilic-congo red derivative X-34, a more sensitive detector of of Aβ aggregates.

W4069C Neuronal HSF-1 cell non-autonomously regulates intestinal DAF-16 functions and longevity in *C. elegans*. *Ji -Yuen Kim*[1], Ao-Lin Hsu[1,2]. 1) Institute of Biochemistry and Molecular Biology, National Yang-Ming University, Taipei, Taiwan; 2) Department of Internal Medicine, Division of Geriatric and Palliative Medicine, University of Michigan, Ann Arbor, MI 48109, USA.

The insulin/IGF-1-like signaling pathway (IIS) is known to have a conserved role in aging. IIS negatively regulates the activity of the FOXO transcription factor DAF-16 and the expression of its downstream target genes. In particular, DAF-16 activity in the intestinal cells is required for the lifespan extension of the IIS pathway mutants. The heat shock transcription factor HSF-1 appears to regulate lifespan and stress resistance as well in *C. elegans*. Previous studies have shown that hsf-1 overexpression extends lifespan, while knock down of HSF-1 by RNAi shortens lifespan. HSF-1, like DAF-16, is required for the IIS pathway mutations to extend lifespan. Moreover, HSF-1 and DAF-16 might act together to activate the expression of a specific subset of genes to promote longevity. Interestingly, previous studies indicated that neural overexpression of hsf-1 is sufficient to promote longevity and it requires the activity of intestinal daf-16. However, how might neuronal HSF-1 communicate with intestinal DAF-16 remains unknown. The aim of our studies is to further dissect the molecular mechanism underlying this inter-tissue communications between neurons and intestine. First, we confirmed that intestinal DAF-16 translocates to nuclear and is activated in response to neural HSF-1 over-expression. The release of neurotransmitters and/or neuropeptides, via synaptic (SVs) and/or dense-core vesicles (DCVs) respectively, constitutes the primary mechanisms for the communication between neighboring or distant cells and organs in response to stimuli. We found that the nuclear localization of DAF-16 is significantly suppressed when several genes involved in DCV trafficking is inhibited by RNAi. Thus, a neuropeptidergic regulation of intestinal DAF-16 may be involved in the longevity phenotypes of HSF-1 OE animals.

W4070A The Spinal Muscular Atrophy Network (SMA) Regulates Insulin Signaling in Response to High-Glucose Diet in *C. elegans*. *Maegan Neilson*[1], Lauren Riley[1], Ryan Buehler[1], Emma Sikes[1], Kevin Deehan[1], Michael Mastroianni[1], John A. Hanover[2], Michael W. Krause[2], Michelle A. Mondoux[1]. 1) College of the Holy Cross, Worcester, MA; 2) National Institute of Diabetes, Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD.

Spinal muscular atrophy (SMA) is a neurodegenerative disease that results in the loss of motor neurons, muscle atrophy, paralysis, and infant mortality. The causative gene of SMA is *SMN1*, which encodes a survival motor neuron protein and is implicated in the regulation of splicing. Our project seeks to establish and characterize a new, promising link between SMA and high-glucose diet in *Caenorhabditis elegans*. *C. elegans* is an excellent model to study SMA, as the *smn-1* gene is nearly 80% identical in worms and humans, and it is also a good model for to study the response to high-glucose diet due to the high level of conservation with the human insulin-signaling pathway.

Mutations in the *C. elegans* insulin receptor (*daf-2)* can lead to entry into an alternative larval stage called dauer. Previous studies have demonstrated that a high-glucose diet suppresses this effect due to the up-regulation of insulin signaling. We conducted a series of RNAi screens to identify regulators that are important for the insulin signaling response specifically on a high-glucose diet. We have identified 44 candidate genes. Interestingly, two of the most promising candidates are *smn-1* and *nekl-3*, the latter of which has been identified as a modifier of *smn-1*. This identifies a potential link between SMA, high-glucose diet, and insulin signaling.

We have completed dauer assays to verify and quantify the insulin specificity and glucose specificity of these 44 candidate genes. ~30 other genes have been identified as *smn-1* genetic interactors, and we have tested whether other members of this "SMA Network" are also involved in regulating insulin signaling. We find that the SMA Network genes are enriched for this response: ~25% are also required for the high-glucose diet suppression of dauer formation. SMA Network genes also seem to play a role in regulating other insulin-signaling phenotypes, including lifespan and stress resistance.

W4071B PROtein FEeding in CElegans (PROFECE) a new method to study gut-microbiota interaction during neuro/muscular development. *f. pio*[1], L. hueber[1], M. Mony[1], M. Cornell[1], A. Chang[1], B. Kong[1], V. Kooner[1], S. Shivji[1], A. Bikov[1], C. Rankin[2], A. Yu[2]. 1) simon fraser university, burnaby, bc, CA; 2) University of British Columbia, vancouver, bc,CA.

Similar to human, the intestine of C. elegans contain and process constantly E.coli bacteria since it fed on bacterial lawn. This observation led us to consider the bacterial lawn of C. elegans not only as a food source but as a microbiota environment. Subsequently, we can modify by genetic engineering this environment to study host-pathogen interaction in the gut of the nematode. Since a nodavirus in C. elegans called orsay was recently discovered we validated this method using this new viral system. In this study, we developed a novel method called PROtein FEeding in C. Elegans (PROFECE) that fed the worm with protein expressed in the E. coli bacterial lawn. We further investigated the effect of the viral proteins alpha and delta during development using survival assay, fluorescence microsocopy and behavioral assay with a multi-wormtracker. Survival assays shows that the viral proteins affect lifespan and provoke intestinal malfunctions and abnormalities. Finally, we observed using wormtrackers that worm fed with E. coli lawn expressing different viral proteins have behavior that is similar but different from the two well described mode of locomotion defined as roaming and dwelling in response to different type of food likelihood. Our results suggest that nematode growing in the presence of the orsay viral proteins have an altered muscular and/or neuronal function.

W4072C The role of Ca^{2+} permeability and Na^{+} conductance in cellular toxicity caused by hyperactive DEG/ENaC channels. *C. Matthewman*[1], T. Miller-Flemming[2], D. M. Miller 3rd[2], L. Bianchi[1]. 1) University of Miami Miller School of Medicine, Miami, FL; 2) Vanderbilt University, Nashville, TN.

Hyperactivated DEG/ENaCs cause neuronal death mediated by intracellular Ca^{2+} overload. Mammalian ASIC1a and *C. elegans* MEC-4(d) neurotoxic channels conduct both Na^{+} and Ca^{2+} raising the possibility that direct Ca^{2+} influx through these channels contributes to the intracellular Ca^{2+} overload. However, we showed that homologous *C. elegans* DEG/ENaC channel UNC-8(d) is not Ca^{2+} permeable yet it is neurotoxic, suggesting that Na^{+} cation influx is sufficient to induce toxicity. Interestingly, UNC-8(d) shows small currents due to extracellular Ca^{2+} block. Thus, MEC-4(d) and UNC-8(d) differ both in current amplitude and Ca^{2+} permeability. Given that these two channels show a striking difference in toxicity, we asked: *what is the contribution of Na^{+} conductance versus Ca^{2+} permeability to cell death in this channel family*. To test the contribution of Na^{+} influx to cell death we replaced Na^{+} with impermeant cation choline and compared current amplitudes and cell death in oocytes expressing either MEC-4(d) or UNC-8(d). We found that cell death is strongly suppressed in UNC-8(d) expressing oocytes under these conditions, but not in oocytes expressing MEC-4(d). These results suggest that main contributor to cell death is Na^{+} for UNC-8(d) and Ca^{2+} for MEC-4(d). To test this hypothesis, we sought to confer Ca^{2+} permeability to the UNC-8 channel by swapping its second transmembrane domain (TM2), which houses the selectivity properties of these channels, with MEC-4. Indeed we found that the UNC-8(d)/MEC-4(TM2) chimeric protein is Ca^{2+} permeable. In addition, the elimination of extracellular Na^{+} from oocytes expressing UNC-8(d)/MEC-4(TM2) did not prevent cell death. Similar results were obtained with oocytes expressing MEC-4(d). These data support the idea that MEC-4(d) Ca^{2+} permeability is conferred by TM2 and that Ca^{2+} contributes to cell death in oocytes expressing Ca^{2+} permeable DEG/ENaCs. To conclude, our data show that both Na^{+} and Ca^{2+} conductance can kill cells that express hyperactive DEG/ENaC channels. However, for Ca^{2+} permeable DEG/ENaCs, Ca^{2+} appears to play a larger role.

W4073A Knock-out of *C. elegans* sirtuin *sir-2.3* protects neurons from death. *R. Sangaletti*[1], M. D'Amico[2], D. Della Morte[3], J. Grant[1], L. Bianchi[1]. 1) Department of Physiology and Biophysics, Miller School of Medicine, University of Miami, Miami, FL; 2) Department for Life Quality Studies, Alma Mater Studiorum,University of Bologna, Rimini, Italy; 3) Department of Neurology, Miller School of Medicine, University of Miami, Miami, FL.

Neurodegeneration that follows a stroke, leads to a serious and devastating damages that affect people's quality of life. No therapeutic agents aimed at preventing neuronal death in stroke and at protecting patients at high risk are available or truly effective. Sirtuins are NAD^{+}-dependent deacetylase proteins found to influence the extent of neuronal death in stroke. However, different sirtuins appear to have opposite roles in neuronal protection. We used well characterized models of neuronal death such as *mec-4(d)*-induced death of touch sensory neurons and anoxic ischemia to test the role of sirtuins in neuronal death in *C. elegans*. We found that knock-out of this mitochondrial *sirtuin 2.3* confers neuroprotection in both models of neurodegeneration. Importantly rescue experiments demonstrated that the effect is mediated by *sir-2.3*. In addition we observed a maximum expression of *sir-2.3* mRNA in wild type animals 4-5 hours after exposure to hypoxic injury. These data confirm the involvement of the mitochondrial *sir-2.3* in neurodegeneration. Since caloric restriction protects against several neurodegenerative and cardiovascular diseases through the activation of sirtuins, we tested the involvement of caloric restriction in the neuroprotection provided by *sir-2.3* knock-out in *mec-4(d)*-induced excitotoxicity neuronal death. We used the well-known genetic model of caloric restriction *eat-2(ad1116)* mutation and we compared the extent of neuronal death in wild-type and *sir-2.3* knock-out backgrounds. Similar analysis was performed *in vitro* where cultured neurons were treated with 2-deoxyglucose (2-DG), which mimics caloric restriction. We found that in both *in vivo* and *in vitro*, caloric restriction enhanced the neuroprotective effect of knock out of *sir-2.3*, but had no effect on basal level of neurodegeneration. These data suggest a synergistic effect of caloric restriction and knock-out of mitochondrial *sir-2.3*. Experiments are under way to establish whether neuroprotection induced by the combination of caloric restriction and *sir-2.3* knock out is mediated by reduced Ca^{2+} overload in these neurons. Our study will lay the groundwork for developing future pharmacologic approaches to prevent and treat neuronal damage in neurological disorders including stroke.

W4074B The effect of sesame lignans on amyloid-beta toxicity in *Caenorhabditis elegans* model of Alzheimer's disease. *R. Keowkase*[1], N. Shoomarom[1], W. Bunargin[1], N. Weerapreeyakul[2]. 1) Srinakharinwirot Univ., Nakornayok, Thailand; 2) Khon Kaen Univ., Khon Kaen, Thailand.

Alzheimer's disease (AD), an age-related neurodegenerative disorders, is widely recognized as a serious public health problem. As lifespan increases, greater proportions of our population are affected by AD. AD is characterized by β-amyloid (Aβ) plaques and neurofibrillary tangles (NFTs) observed in the brain tissue. The treatment of AD is currently limited to the symptomatic treatment with two classes of the US FDA approved drugs which are acetylcholinesterase inhibitors and N-methyl-D-aspartate receptor antagonist. These drugs have a limited efficacy and are considered to be effective only in a short period of time. At this point, there is still no approved treatment with a proven disease-modifying effect. This leads to the need for the development of effective compounds that can provide disease-modifying property. Oxidative stress is known to play an important role in AD, and there is strong evidence linking oxidative stress to Aβ. Sesame seed (*Sesame indicum*) has been known as a natural healthy food in East Asian countries. Many evidences suggested that sesame lignans including sesamin, sesamolin, and sesamol obtained from sesame seed possess antioxidant property. To test whether these sesame lignans exhibit benefit effects in AD, the nematode *Caenorhabditis elegans* (*C. elegans*) was utilized. To develop transgenic *C. elegans* model of AD, human Aβ is expressed intracellularly in the body wall muscle. The expression and subsequent aggregation of Aβ in the muscle lead to paralysis. The mechanism by which Aβ induced toxicity causing worm paralysis is believed to result from oxidative stress. The purpose of this study was to investigate the protective effect of sesame lignans (sesamin, sesamolin, and sesamol) against Aβ toxicity using *C. elegans* model of AD. Of these three sesame lignans, we found that only sesamin and sesamolin significantly delayed Aβ-induced paralysis. Sesamin and sesamolin delayed the paralysis in this model by 2 h and 1.8 h, respectively. This result suggests that sesamin and sesamolin can reduce Aβ toxicity. The mechanism by which sesamin and sesamolin delaying Aβ-induced paralysis is under investigated.

W4075C Nematode disease model of Niemann-Pick C yields pharmacological bypass suppressors. *E. O. Perlstein*. Perlstein Lab PBC, San Francisco, CA.

Perlstein Lab PBC (PLab) has built an automated model-organism-based drug discovery platform for rare genetic diseases, starting with Niemann-Pick Type C/NPC. Using CRISPR we generated null alleles of NPC1 orthologs in nematodes and flies, resulting in mutant animals that exhibit developmental delay and larval lethality, respectively. We then screened those models against a 50,000-compound library to identify small molecules that reverse disease phenotypes in whole animals. In less than a year, we discovered and validated a novel pharmacological bypass suppressor called PERL101. PERL101 is one of 14 unoptimized primary screening hits that modifies developmental phenotypes in ncr-1 null worms and cholesterol-storage phenotypes NPC patient fibroblasts. At the same time, PERL101 has excellent pharmaceutical properties such as 100% oral bioavailability, CNS penetration and tolerability in mice. Based on preliminary mechanism-of-action studies in both worms and mammalian cells, PERL101 modulates autophagy, an evolutionarily conserved pathway that has been implicated in NPC disease and other lysosomal storage disorders.

W4076A Characterizing the role of *swip-10* in the glutamatergic regulation of *C. elegans* dopamine neuron morphology. *C. Snarrenberg*[1,2], J. Balbona[1], J. Hardaway[1], A. Niedzwiecki[3], R. Blakely[2]. 1) Vanderbilt University, Nashville, TN; 2) Florida Atlantic University, Jupiter, FL; 3) Eckerd College, St. Petersburg, FL.

Precise coordination between L-glutamate (GLU) and dopamine (DA) neurotransmission drives many complex behaviors such as locomotion, reward and learning. Perturbations in the normal interactions of these neurotransmitters are believed to drive an array of brain disorders including addiction, schizophrenia and Parkinson's disease. Using the genetic model system *C. elegans*, we identified a conserved, glial-expressed gene, *swip-10,* that acts as a glutamatergic regulator of DA signaling. We have shown that mutations in *swip-10* lead to increased DA neuron excitability, elevated rates of DA vesicle fusion and the hyperdopaminerigic phenotype, Swimming induced paralysis (Swip). Glial-specific expression of wildtype *swip-10* restores normal DA neuron excitability as well as normal swimming behavior. Moreover, pre- and post-synaptic genetic disruptions of GLU signaling suppress Swip. Based on these studies, and well known findings that vertebrate glia regulate neuronal excitation via tight buffering of extracellular GLU levels, we hypothesize that *swip-10* functions in glial pathways that normally limit extracellular GLU availability and that loss of swip-10 expression drives GLU-dependent elevations in DA neuron excitation and DA release. Elevated extracellular GLU availability in the mammalian brain can alter neural morphology and ultimately lead to excitotoxic cell death. We find that *swip-10* DA neurons exhibit significant dystrophic processes, shrunken and/or missing cell soma, which are suggestive of progressive stages of excitotoxiticity. Glial-specific expression of wildtype *swip*-10 restores normal DA neuron morphology. Moreover, genetic disruption of GLU release by loss of the vesicular GLU transporter type 3 (*vglu-3),* suppresses the DA neuron morphology changes of *swip-10* mutants. Lastly, post-synaptic genetic disruption of GLU signaling through loss of select GLU receptors also suppresses *swip-10* DA neuron morphology alterations. Our studies indicate that whereas *swip-10* mutants exhibit hyperdopaminergia linked to the Swip phenotype, they also appear to be undergoing GLU-dependent morphological changes, consistent with an excitotoxic insult. Ongoing genetic, biochemical and pharmacological studies seek to further elaborate the glial pathways through which *swip-10* regulates extracellular GLU homeostasis and DA neuron morphology.

Supported by NIH Award MH095044 (R.D.B.).

W4077B Functional analysis of VPS41-mediated protection from β-Amyloid cytotoxicity. *E. F. Griffin*, K. A. Caldwell, G. A. Caldwell. University of Alabama, Tuscaloosa, AL.

According to the Alzheimer's Association 2012 report, 13% of Americans over 65 years of age, and approximately half of Americans over the age of 85, suffer from Alzheimer's Disease (AD), resulting in an estimated cost of 200 billion dollars for related health care. Additionally, AD is the most prevalent dementia, and the sixth leading cause of death in the United States. Thus, investigating mechanisms of pathophysiology and identifying potential therapeutic targets for AD is significant.

AD is characterized by the formation of plaques, composed primarily of the amyloid-β 1-42 (Aβ) peptide in the brain, resulting in

neurodegeneration. Our lab has observed that over-expression of human VPS41 in *C. elegans* provides neuroprotection from Aβ toxicity, and that depletion of VPS41 in worms expressing Aβ increases the neurotoxicity of Aβ. In yeast, VPS41 has been demonstrated to function in the tethering of vesicles, late endosomes, and AP-3-coated vesicles from the late Golgi, to the lysosome for degradation. Previously, our lab has shown that over-expression of human VPS41 is neuroprotective in a transgenic worm model of Parkinson's Disease, wherein dopaminergic neurodegeneration is induced by α-synuclein overexpression (Harrington et al., 2012, *J. Neurosci*.). VPS41-mediated neuroprotection from α-synuclein-based degeneration was abolished by mutation of putative phosphorylation sites in VPS41 and was dependent on its interactions with AP-3δ, RAB7, VPS core proteins, and VPS39. Thus, VPS41 has a role in lysosomal trafficking that impacts neuron survival.

The objective of this study is to determine how this specifically relates to cellular processing and ameliorates the impact of neurotoxic proteinaceous products. Here we report the results of a systematic RNAi screen whereby we knocked down the core components involved in lysosomal trafficking and categorized their requirement for Aβ protein toxicity. Our results indicate that the ARF-like GTPase *arl-8* mitigates endocytic Aβ neurodegeneration in a VPS41-dependent manner, rather than through *rab-7* and AP-3-coated vesicles from the late Golgi as with α-synuclein. Additionally, we suggest that the GABARAP homologue, *lgg-2*, plays a critical role in Aβ toxicity with *arl-8*. In this regard, further analysis of functional effectors of Aβ protein processing via the lysosomal pathway, along with subsequent evaluation in our worm neuronal model of AD (Treusch et al, 2011, *Science*), will assist in the elucidation of the underlying mechanism involving VPS-41-mediated neuroprotection.

W4078C Sexually antagonistic male signals manipulate germline and soma of *C. elegans* hermaphrodites. *I. Ruvinsky*, E. Aprison. Univ Chicago, Chicago, IL.

Males and females communicate via chemical signals, some of which are detrimental to the recipient. It has been reported previously that *C. elegans* hermaphrodites age more rapidly in the presence of male-secreted signals, even when no live males are present. Here we show that this is due, at least in part, to two distinct secreted signals via which *C. elegans* males manipulate reproductive physiology of hermaphrodites. The first, mediated by conserved ascaroside pheromones, counters the loss of germline stem cells that occurs during aging. The second signal, which is species-restricted, accelerates development and results in faster sexual maturation. Several conserved signaling pathways play specific key roles in these processes. The two modes of chemical communication we report promote males' evolutionary interests by ensuring that potential mates are mature and have sufficient gametes for successful reproduction. Effects harmful to hermaphrodites appear to be collateral damage rather than the goal of secreted signals produced by males.

W4079A Characterization of a CRISPR/Cas9 Mediated *C. elegans* HSF-1 Model Reveals a Complex Oxidative Response and Novel Oocyte Expression. *A. Deonarine*, M. Noble, L. Bowie, S. Westerheide. University of South Florida, Tampa, FL.

The transcription factor Heat Shock Factor-1 (HSF-1) regulates the Heat Shock Response (HSR), a cytoprotective response induced by various proteotoxic stresses. Recent data from model organisms also suggests that HSF-1 is involved in non-stress roles including the regulation of development and longevity. In order to better study HSF-1 function in a whole organism model, we have created a *C. elegans* strain containing HSF-1 tagged with GFP at its endogenous locus utilizing CRISPR/Cas9-guided transgenesis. Previous *C. elegans* models with tagged HSF-1 have relied on rescuing a mutant variant of HSF-1 in an exogenous locus, but it has been noted that mutant variants of HSF-1 can still retain some regulatory function in *C. elegans* and other organisms. This may lead to non-representational data of HSF-1 regulation collected in existing *C. elegans* models. Our endogenously tagged HSF-1 model should therefore provide more accurate data on HSF-1 function. We show here that our HSF-1::GFP is functional, as our worm strain behaves similarly to wild-type worms as well as to a previously described HSF-1::GFP model in response to heat stress, sodium azide, osmotic stress, and acute cadmium exposure. Upon further characterization of our HSF-1::GFP strain, we observe robust HSF-1 expression in the oocytes of *C. elegans*, which previously has not been reported, as well as a more complex response to oxidative damage than previously described. Further studies are planned with our model to investigate these and other potential new roles for HSF-1 in organismal biology. This model thus is unique in that it is the only endogenously-tagged HSF-1 whole-organism model currently available, and represents a novel experimental platform to study HSF-1 function within and outside of the HSR.

W4080B Identifying Intrinsic Modulators of Neuronal Resilience in the *C. elegans* Dopaminergic System. *A. Gaeta*, K. Caldwell, G. Caldwell. University of Alabama, Tuscaloosa, AL.

It has long been observed that a subset of individuals within a population respond more favorably to stress than the rest of the population. This study aims to uncover the intrinsic molecular and cellular factors that modulate the protective effects toward a specific stressor: the toxic misfolding of the human α-synuclein protein, which is implicated in the degeneration of dopamine neurons in Parkinson's Disease. Previously published work from our group has established that isogenic populations of the nematode *C. elegans* overexpressing α-synuclein from an integrated transgene exhibit reproducible and progressive age-dependent dopaminergic neurodegeneration. By utilizing this model system, we hypothesized that genetic and epigenetic factors, along with downstream targets of these factors, can be discovered that relate to the resilience exhibited by select animals in combating the stress of α-synuclein in dopamine neurons more effectively than others. We have developed a trans-generational behavioral enrichment scheme whereby individuals that express α-synuclein in dopamine neurons are selected for resilience in the context of the Basal Slowing Response (BSR), a quantifiable readout associated with dopamine neuron dysfunction. Selective propagation of animals that exhibit a BSR more like wild-type across subsequent generations has yielded heritable enrichment that has been found to last through four or more generations, after which it resets to resemble the defective BSR that individuals expressing α-synuclein in dopamine neurons characteristically exhibit. Along with examining the degeneration of dopamine neurons in strains of *C. elegans* over-expressing candidate neuro-protective genes, as well as strains of *C. elegans* under-expressing these same genes via RNAi, a better

understanding of the innate cellular mechanisms that resilient individuals employ to actively combat the stress of α-synuclein in dopamine neurons can be ascertained.

W4081C Investigating DNA damage response pathways after exposure to various heavy metals in *C. elegans*. *J. Hall*, S. Koga, S. Parag, K. Campbell, M. McMurray. Lincoln Memorial University, Harrogate, TN.

A major route of exposure to various heavy metals is through contaminated soil and water. Research has shown that these substances play roles in the induction of various diseases such as cancer, neurodegeneration and birth defects. In the cell, proteins such as metallothioneins respond to heavy metal exposure and chelate the metal to prevent cellular damage. However, little is known about the cellular response in regards to DNA damage after heavy metal exposure. To provide a better understanding of this cellular response, the induction of both cell cycle arrest and apoptosis were investigated after exposure to copper, cadmium, iron, lead, nickel and silver in the nematode *C. elegans*. Growth assays were conducted to determine EC10 and EC50 concentrations which were utilized to determine the DNA damage response pathway, apoptosis and/or cell cycle arrest, being induced upon exposure. Apoptosis and cell cycle arrest were observed in the germline after 24 hour exposure to the heavy metal. Apoptosis in the germline was induced in response to both concentrations of nickel. Additionally, apoptosis was also observed in the early embryo after nickel exposure suggesting an effect on reproduction rates. Both iron and silver exposure resulted in a slight increase in apoptosis at the EC50 concentration. Apoptosis and cell cycle assays for all metals tested will allow us to better understand the damage being caused by the metal exposure as well as mechanisms induced by the cell in response to exposure.

W4082A Functional regulation of the DAF-16 by CBP-1-dependent acetylation in response to multiple stressors. *A. L. Hsu*[1,2,3], C. Y. Liang[1], X. K. Yu[2], W. C. Chiang[3], D. Lombard[4]. 1) Institute of Biochemistry and Molecular Biology, National Yang-Ming University, Taipei, TAIWAN; 2) Department of Internal Medicine, Division of Geriatric and Palliative Medicine, University of Michigan, Ann Arbor, USA; 3) Department of Molecular and Integrative Physiology, University of Michigan, Ann Arbor, USA; 4) Department of Pathology, University of Michigan, Ann Arbor, USA.

All living organisms face a challenge to sense and respond appropriately to the environmental cues. In *C. elegans*, the FoxO transcription factor DAF-16 translocates into nucleus upon stress to regulate gene expression for organismal survival. The subcellular localization and activity of DAF-16 are tightly controlled by its post-translational modifications, including phosphorylation, acetylation, ubiquitination, methylation and glycosylation. In our previous study, we found that sirtuin family protein SIR-2.4, a homolog of mammalian SIRT6 and SIRT7, promotes DAF-16 nuclear translocation and DAF-16-dependent transcription under stress conditions. SIR-2.4 acts antagonistically with the acetyltransferase CBP-1 to negatively regulate DAF-16 acetylation. However, this modulation does not require the catalytic activity of SIR-2.4. We further identified four CBP-1-mediated acetylation sites on DAF-16 by mass spectrometry analysis. Mutations on some of these acetylation sites alter the kinetics of DAF-16 translocation upon stress, indicating a new nuclear localization signal of DAF-16. Furthermore, mutations on these acetylation sites affect both the lifespan and stress resistance of the animals, possibly due to an increased DAF-16 transactivating activity. Together, our studies identify acetylations on DAF-16 protein that significantly affect its functions in response to stress.

W4083B Environmental stresses induce transgenerationally inheritable survival advantages via germline-to-soma communications. *S. Kishimoto*, M. Uno, E. Nishida. Kyoto University, Kyoto, Japan.

Hormesis, a biologically beneficial response to low-dose exposure to stressors, has been reported to improve the functional ability of cells and organisms. Recent studies suggest that ancestral environmental conditions can influence the phenotypes of progeny. However, a key question of whether parents can transmit the beneficial memory of hormesis effects to their descendants remains largely unanswered. Here we show that hormesis effects induced in the parental generation can be passed on to the descendants in *Caenorhabditis elegans*. Animals subjected to various stressors during developmental stages exhibit increased resistance to oxidative stress and proteotoxicity. The increased resistance is transmitted to the subsequent generations grown under unstressed conditions. Remarkably, exposure of the male parents to these stressors also increases the stress resistance of the descendants and extends their lifespan. These findings suggest that the memory of hormesis effects can be transmitted to progeny through germline epigenetic alterations. Our analysis also shows that the insulin/ IGF-like signalling effector DAF-16 and the heat-shock factor HSF-1 in the parental somatic cells mediate the formation of epigenetic memory, and that the histone H3 lysine 4 trimethylase complex functions in the germline through generations to maintain the memory. Based on these results, we propose the germ-to-soma communications across generations as an essential framework for the transgenerational inheritance of acquired traits.

W4084C The *C. elegans* mitochondrial unfolded response induces dopaminergic neurodegeneration under prolonged cell-autonomous over-activation. *B. A. Martinez*, D. A. Petersen, S. P. Stanley, G. A. Caldwell, K. A. Caldwell. University of Alabama, Tuscaloosa, AL.

Mitochondrial protein folding disruption leads to recruitment of ATFS-1 in *C. elegans* to effect the mitochondrial unfolded protein response (mtUPR). Organismal ATFS-1 signaling has been linked to pathogen resistance as well as lifespan extension during prolonged electron-transport chain (ETC) disruption. However, after ETC disruption or successful pathogen avoidance, the mtUPR is presumably shut down to resume normal metabolism and protein regulation. Over-activation of this pathway, especially in the absence of stressors, is not especially well characterized from a cellular health perspective and is relevant to the mechanistic understanding of neurodegenerative disorders linked to mitochondrial dysfunction.

Here we describe consequences of over-activated ATFS-1 signaling in *C. elegans* neurons. To ascertain the role of cell-autonomous ATFS-1 we overexpressed cDNA construct variants in dopaminergic neurons and found that wild-type overexpression produces neuroanatomical changes including soma swelling. However, a constitutively active variant induces these neuroanatomical changes as well as severe age-dependent degeneration. This degeneration is not seen in variants of ATFS-1 with nuclear import or the bZIP domain mutations, suggesting that it is the

altered and ectopic gene expression induced by ATFS-1 which leads to neurodegeneration. Counterintuitively, the ATFS-1 degenerative phenotype can be attenuated by addition of a chronic stressor of the ETC such as rotenone, suggesting that cells may differentiate between chronic and acute signaling paradigms and may implicate organismal signaling mechanisms towards cellular survival. Next, we report a role for α-synuclein (αS), a Parkinson's disease-associated protein, in altering ATFS-1-mediated toxicity. We find that αS neurotoxicity is enhanced in gof ATFS-1 but reduced in a loss-of-function (lof) mutant. In addition, protein misfolding and αS::GFP bodywall aggregation is reduced in lof ATFS-1 animals suggesting differentially regulated protein handling may underlie ATFS-1 cellular toxicity. We confirmed that ATFS-1 could induce αS toxicity in a cell-autonomous fashion by crossing ATFS-1 cDNA variants into animals that express αS in dopaminergic neurons, finding degrees of age-dependent synergistic toxicity. Lastly, variants on αS possess the ability to differentially induce the mtUPR suggesting that αS may interact with the mitochondria, inducing stress, and potentially influencing cell survival through mechanisms associated with the mtUPR. These findings advance understanding of mitochondrial quality control insofar as organismal signaling and cell-autonomous health coordinate to maintain homeostasis.

W4085A Chromatin remodeling proteins influence the Heat Shock Response in *Caenorhabditis elegans*. *Mark Noble*, Andrew Deonarine, Lori-Ann Bowie, Sandy D. Westerheide. University of South Florida , Tampa, FL.

The Heat Shock Response (HSR) is an essential, highly conserved stress pathway that maintains protein homeostasis (proteostasis) by resolving misfolded proteins and detrimental protein aggregates. Recent studies in *C. elegans* have demonstrated that chromatin remodeling during the transition from larva to adulthood causes an abrupt decline in the heat shock response. To further our knowledge as to which chromatin remodeling factors may influence the HSR in an age-dependent manner, we have performed an RNAi sub-library screen of 62 chromatin remodeling factors across the larval stages to adulthood in *C. elegans*. Initiating RNAi at L1, we utilized a worm strain carrying the heat-inducible transcriptional reporter p*hsp-16.2*::GFP and the constitutive RFP construct p*dop-3*::RFP. We then treated the worms with or without heat shock at the L4/YA stage or 24 hours later during active reproduction. The regulators we identified to either positively or negatively influence the HSR in an age-dependent manner include Nucleosome Remodeling Factor (NURF) complex members, SWI/SNF family genes, and histone deacetylases. Of these hits, PYP-1, an inorganic pyrophosphatase and member of the NuRF complex, stood out as our strongest hit. PYP-1 negatively regulates the HSR only after the onset of reproduction. After this transition, *pyp-1* knockdown causes activation of both *hsp-70* and *hsp-16.2* transcriptional reporter animals during both non-stress and stress conditions. While *pyp-1* RNAi does not affect overall juvenile development and lifespan, it completely eliminates reproduction. This uncoupling of stress activation, reproduction, and lifespan by *pyp-1* knockdown appears to be a unique physiological feature, since cell physiological changes that activate stress responses typically trade-off reproduction and yield increased cell survival and longevity. We are interested in further characterizing PYP-1 function during the transition to adulthood as a way to epigenetically regulate the heat shock response upon aging and we are interested the mechanism in the uncoupling of longevity, reproduction, and development.

W4086B Determining the Role of DBL-1 TGF-β Signaling in the Response to Potential Therapeutic Compounds in the *C. elegans* Model System. *G. Ravindranathan*[1], R. A. Veettil[1], A. Gekombe[1], S. Ghosh[2], D. Dolliver[3], D. Hynds[1], M. Bergel[1], T. L. Gumienny[1]. 1) Texas Woman's University, Denton, TX; 2) Southeast Missouri State University, Cape Girardeau, MO; 3) Southeastern Louisiana University, Hammond, LA.

Development of therapeutic drugs is a challenging and lengthy process. It is vital to understand the reactions of the system being treated — both intended and side effects — and the best dosage for maximum efficacy with minimum side effects or long-term effects. Due to the complexity of human systems and ethical issues, the effect of a drug/compound cannot be directly tested without pre-clinical trials. *C. elegans* is an animal system for testing the toxicity of candidate compounds, and can provide preliminary data to justify the time, effort, and expense of pre-clinical studies in vertebrate models. We predict that *C. elegans* responds to toxic compounds using a conserved stress response pathway, the TGF-β pathway. Our goals are to 1) determine how *C. elegans* responds to potential therapeutic compounds, including nanocarriers and amidoximes (potential anti-cancer drugs), and 2) determine if the DBL-1 TGF-β pathway is required for a general stress response to toxic compounds. We first established whether potential drug delivery vehicles (three nanocarriers) and anti-cancer drugs (two amidoximes) show toxicity by determining the lethal concentration (LC50) on wild-type animals. Milder effects of these compounds on the organism were determined by assaying growth rate, body morphology, brood size, and aversion to the compounds. To determine the role of the DBL-1 TGF-β signaling pathway in the organismal response to abiotic stress, we are analyzing the effect of increased and decreased DBL-1 TGF-β pathway signaling on the animals' response to these and other established toxic compounds.

W4087C Interaction of telomerase deficiency with stress response pathways. *Maya Spichal*[1], Megan Brady[1], Chen Cheng[1,2], Shawn Ahmed[1]. 1) University of North Carolina, Chapel Hill, NC; 2) University of California, Berkeley, CA.

In the absence of telomerase telomeres shorten with very cell division leading to cell cycle arrest and senescence. Alternative lengthening of telomeres (ALT) can rescue cells from their proliferation arrest and was found to be the primary cause in 10% of all cancer types.

In *C. elegans* deficient for the telomerase reverse transcriptase subunit *trt-1*, telomeres shorten every generation affecting germline cells with little or no effect on somatic cells or lifespan (1, 2). While *trt-1* worms grown under optimal conditions become sterile after about 20 generations, *trt-1* worms grown under stressful conditions can survive indefinitely via ALT, suggesting an interaction between stress response pathways and telomere biology (3).

Additionally, telomere shortening could activate stress pathways long before complete telomere attrition as various forms of DNA damage were shown to trigger an innate immune response in *C. elegans* (4).

Under stressful conditions worms can develop into stress resistant dauer larvae to promote survival. Here we address two of the four dauer arrest stress response pathways. Preliminary results indicate that deficiency for telomerase in conjunction with deficiency for either the TGF-b

or the lifespan extending insulin/IGF pathway may each lead to distinct synthetic interactions that could be generally relevant to deficiency for telomerase in the context of aging or cancer.

W4088A *in vivo* mechanisms of epithelial junction formation. *Jose Montoyo-Rosario*, Jeremy Nance. NYU School of Medicine, New York, NY.

Epithelial cells are specialized cells that line our organs and connect together with adhesive junctions. Loss of junctions compromises tissue structure and has been linked to human disease, such as kidney disease, cancer, and birth defects. We are investigating how cell junctions form in developing epithelia. Previous studies from our lab demonstrated that PAR-6 is required for junctions to mature in differentiating epithelial cells. PAR-6 functions together with the kinase PKC-3, but the targets of PKC-3 important for junction formation are largely unknown. Using a temperature-sensitive hypomorphic allele of *pkc-3*, we found that junctions in the spermatheca can break in mutant animals, leading to sterility. To find genes that function together with *pkc-3* to regulate junctions, we performed a suppressor screen to identify *pkc-3* mutants that are fertile at the restrictive temperature. We isolated 27 independent mutations, including six intragenic mutations in the *pkc-3* gene. We have also identified a new allele of a known *pkc-3* regulator, *lgl-1;* and identified two different alleles of *F22F4.1,* an uncharacterized gene. We are using whole genome sequencing to clone the remaining six mutants, and will characterize their function in junction maturation.

W4089B Non-autonomous roles of posterior *Hox* genes and SPON-1/F-Spondin in Q descendant migration. *Matthew P. Josephson*, Adam M. Miltner, Erik A. Lundquist. University of Kansas, Lawrence, KS.

MAB-5/Hox and LIN-39/Hox have well-defined opposing, cell autonomous roles in QL and QR migration, respectively. Here we demonstrate overlapping roles of these genes in Q descendant migration, and find a non-autonomous role for MAB-5 in this regard. The QR and QL descendants AQR and PQR migrate long distances in opposite anterior-posterior directions. The Hox transcription factor LIN-39 cell-autonomously promotes anterior migration of the QR lineage, and MAB-5/Hox cell-autonomously promotes posterior migration of the QL lineage. We have discovered parallel, roles for LIN-39, MAB-5, and another posterior Hox factor EGL-5 in migration of both QR and QL lineages. Additionally we show that MAB-5, and EGL-5 can function non-autonomously to promote Q lineage migration. Although alone, *mab-5* mutants have anteriorly-misdirected PQR (from the QL lineage), and *lin-39* have weak defects in anterior AQR migration (from the QR lineage), the *lin-39 mab-5* double mutant displayed severe anterior migration defects of both AQR and misdirected PQR. *mab-5* is not expressed in the QR lineage, and *lin-39 mab-5* defects were rescued by *mab-5* expression from posterior body wall muscles, demonstrating a non-autonomous role of MAB-5 in Q descendant migration. *egl-5* mutants displayed AQR and PQR defects that were rescued by muscle-specific *egl-5* expression, indicating a non-autonomous role of EGL-5 in AQR and PQR migration. In the triple mutant *lin-39 mab-5 egl-5,* AQR and PQR largely failed to migrate from the Q cell birthplace, indicating parallel roles of LIN-39, MAB-5, and EGL-5, likely in body wall muscles, in Q descendant migration. We hypothesize that *Hox* genes both pattern the posterior region of the animal creating an environment amenable for Q cell migration (non-autonomous role), and control how the Q cells respond to that environment (autonomous role). An RNA seq study identified *spon-1* as a potential MAB-5 target gene. *spon-1* encodes a secreted cell adhesion molecule implicated in muscle and neuronal adhesion similar to vertebrate *F-spondin.* We show that *spon-1* non-autonomously controls Q descendant migration through expression in posterior body wall muscles, and that MAB-5 activity drives expression from the *spon-1* promoter in body wall muscles, confirming the RNA seq result. Further studies are aimed at testing the idea that *spon-1* is a target of MAB-5 in body wall muscles. In sum, these studies demonstrate non-autonomous roles of Hox genes and SPON-1 in migration of the Q descendants AQR and PQR.

W4090C Analyzing phosphorylation of LIN-31, a transcription factor involved in *C. elegans* cell fate specification. *Hannah Kortbawi*, Alexandra Smallwood, Leilani Miller. Santa Clara University, Santa Clara, CA.

The development of the vulva in *Caenorhabditis elegans*, a soil nematode, is believed to be reliant on the phosphorylation of LIN-31, a winged-helix transcription factor. LIN-31 is part of the Ras/MAP Kinase (MAPK) cell-signaling pathway. When MPK-1, a protein in the Ras/MAPK pathway upstream of LIN-31, is phosphorylated, it enters the nucleus and phosphorylates LIN-31. MPK-1 can phosphorylate any of four consensus sites on the transcription factor, which are a serine or a threonine adjacent to a proline. It is not clear, however, whether or not all four consensus sites are phosphorylated by MPK-1. Understanding this is key to learning more about how LIN-31 affects vulval development. Using PIPE cloning and Gibson Assembly, a “phosphorylation library” of all of the different consensus site combinations was successfully created. This was verified by sequence analysis.

W4091A *C. elegans* immunoglobulin superfamily members, *syg-2* and *syg-1*, genetically interact with *mig-5/dishevelled* to control anteroposterior neurite growth of GABAergic motor neurons. *D. Tucker*[1], B. Ackley[1]. 1) University of Kansas, Lawrence, KS; 2) University of Kansas, Lawrence, KS.

Proper development of the nervous system requires directed axonal outgrowth. During early development in *C. elegans*, the VD GABAergic motor neuron axons are directed anteriorly. Previously, we found that *fmi-1/Flamingo*, the single *C. elegans* member of the Celsr-like cadherin

superfamily interacts synergistically with Wnt pathway components to regulate anteroposterior (A/P) axonal outgrowth of the VD neurons. In mutant animals, some VD neurons exhibit posterior neurite (PN) outgrowth instead of the stereotypical anterior neurite (AN). In a forward enhancer genetic screen for molecules that demonstrate synergy with the Wnt pathway component, *mig-5,* to direct A/P outgrowth, we recovered an allele of the cell-adhesion molecule *syg-2*. To facilitate our genetic analyses, we focused entirely on PNs that occurred in the tail of the animal, where there are normally no GABAergic axons present. In this we found that, individually, loss of function in either *mig-5* or *syg-2* resulted in a PN in approximately 2% of animals, while 25% of the double mutants had a PN. We found that mutations in the SYG-2 interacting protein, SYG-1, also demonstrated synergy with *mig-5* to direct A/P outgrowth, with a similar penetrance in the double mutants. Next we examined interactions between *syg-2* and *fmi-1.* Previously we had reported that 25% of *fmi-1;mig-5* mutants exhibited PNs, just like the *mig-5;syg-2* mutants. Double mutants of *syg-2* and *fmi-1* were not synergistic, rather they appeared to be additive (4% penetrance), although, it was also possible that these genes are functioning in a linear pathway. To determine this we examined the triple mutants of *fmi-1;mig-5;syg-2*, which exhibited PNs in 39% of animals. This suggested that *fmi-1* and *syg-2* were likely functioning in overlapping pathways, both of which are in parallel to *mig-5.* Recently however, during analysis of the *mig-5;syg-2* doubles we observed PNs emanating from DD6 (in L1 animals). Our previous work showed that the DD neurons were not affected by loss of function in *fmi-1*. Thus, it is possible the higher penetrance is due to defects present also in DD neurons. We are currently examining the L1 stage animals from the relevant mutant backgrounds to differentiate between these two models. We are also examining where *syg-1* and *syg-2* are functioning during GABAergic axon development.

W4092B A RhoGAP responds to axonal guidance signals to regulate actin nucleation during *C. elegans* morphogenesis. *Andre Wallace*, Martha Soto. Rutgers - Robert Wood Johnson Medical School, Piscataway, NJ.

The cell migrations that occur during *C. elegans* morphogenesis are meticulously regulated by rearrangement of the actin cytoskeleton. To understand how this process is regulated requires identifying the molecules that function to maintain the balance of forces during F-actin nucleation. Our lab previously showed that three axonal guidance signals, UNC-40/DCC, SAX-3/Robo, and VAB-1/Eph, function upstream of the CED-10/Rac-1 GTPase to modulate actin nucleation in a pathway centered on activation of the WAVE/SCAR complex. In an RNAi screen for regulators of the WAVE/SCAR pathway, we identified the *C. elegans* homolog of vertebrate Myosin IX, HUM-7. Loss of *hum-7* alone results in a small percentage of dead embryos, most of which have morphogenesis defects similar to what is seen in WAVE mutants. Like its vertebrate homolog, Myo9, HUM-7 has a myosin domain in its head and a RhoGAP domain in its C-terminus. Loss of *hum-7* suppressed embryonic defects in *sax-3* mutants, enhanced defects in *unc-40* and did not alter the embryonic defects observed in *vab-1* mutants. The effects of *hum-7* on these axonal guidance mutants is conserved post-embryonically since similar genetic interactions were observed in the guidance of AVM touch neuron. Loss of *hum-7* enhanced *unc-40* neuronal defects, suppressed *sax-3* but did not alter *vab-1* neuronal defects. To understand how an axonal signal acting on a RhoGAP results in morphogenesis defects, we tested which GTPase is being regulated by this candidate RhoGAP, and what loss of this protein does to F-actin levels and dynamics. While Rac is essential for epidermal enclosure migrations, genetic and biochemical tests suggest that HUM-7 is a GAP for Rho-1. Live imaging of F-actin in the migrating epidermis of the developing *C. elegans* embryo shows that loss of *hum-7* results in elevated actin levels and increased F-actin protrusions at the leading edge of the ventral cells. Similar phenotypes were observed in other mutants known to increase Rho-1 activity suggesting that HUM-7 functions through Rho-1 to modulate actin events during embryonic morphogenesis. The increased F-actin levels observed in *hum-7* mutants are similar to those observed in *vab-1* mutants. This observation, coupled with the fact that loss of *hum-7* causes no further impact on loss of *vab-1* embryonically and post embryonically suggests that HUM-7 is functioning in a pathway with VAB-1 to control RHO-1 during the ventral enclosure step of *C. elegans* morphogenesis.

W4093C Using *C. elegans* PVD Neurons to Functionally Validate Neuropsychiatric Risk Genes. *Cristina Aguirre-Chen*[1], Nuri Kim[2], Christopher M. Hammell[1]. 1) Cold Spring Harbor Laboratory, Cold Spring Harbor, NY; 2) Medical Scientist Training Program (MSTP) at Stony Brook University, Stony Brook, NY.

One of the primary challenges in the field of psychiatric genetics is the lack of an *in vivo* model system in which to functionally validate candidate ***n***europsychiatric ***r***isk ***g***enes (NRGs) in a rapid and cost-effective manner. To overcome this obstacle, we performed a candidate-based RNAi screen in which *C. elegans* orthologs of human NRGs were assayed for dendritic arborization and cell specification defects using *C. elegans* PVD neurons. Of 66 NRGs, identified via exome sequencing of autism (ASD) or schizophrenia (SCZ) probands and predicted to result in a loss of protein function, the *C. elegans* orthologs of 6 NRGs were found to be required for proper neuronal development and represent a variety of functional classes, including transcriptional regulators and chromatin remodelers, molecular chaperones, and cytoskeleton-related proteins. We find that RNAi phenotypes associated with the depletion of NRG orthologs is recapitulated in genetic mutant animals, and, via genetic interaction studies, we place a subset of NRG orthologs in the SAX-7/MNR-1/DMA-1 signaling pathway. Collectively, our studies demonstrate that *C. elegans* PVD neurons are a tractable model in which to discover and dissect the fundamental molecular mechanisms underlying neuropsychiatric disease pathogenesis.

W4094A Impact of endocrine signaling on dendrite morphology during development. *C. E. Richardson*[1], K. Shen[1,2]. 1) Stanford, Stanford, CA; 2) Howard Hughes Medical Institute, Chevy Chase, MD.

In the nematode *Caenorhabditis elegans*, the PVD sensory neuron has an elaborate dendritic arbor that enervates the majority of the worm's body wall muscles. During standard growth conditions, PVD dendrite morphology is effected through a well-characterized spatial and temporal growth program, and many of the molecular mechanisms which regulate this process have been described. We observe that adverse environmental conditions induce morphological plasticity in the development of the PVD dendritic arbor. This altered morphology is most

notable in regard to dauer diapause – the stress-resistant alternative to larval stage 3 (L3). Larvae can survive for months in the dauer stage and re-enter normal reproductive development as L4s when environmental conditions improve. There are two modes of dauer-related morphological plasticity of the PVD dendrite: first, dauer diapause induces suspension of dendrite growth; second, after recovery from dauer, PVD exhibits exuberant dendrite elaboration. Surprisingly, mutants that increase the propensity of larvae to enter dauer instead of L3, the *daf-c* mutants, exhibit exuberant dendrite growth without going through dauer, suggestive that it is the dauer signaling components rather than the dauer pause itself that regulates the exuberant growth phenotype. We are developing genetic tools to characterize the tissue-specificity of dauer signaling components in regulating PVD dendrite morphology, and we are identifying the cell-intrinsic dendrite outgrowth mechanisms that are alternately regulated to mediate this morphological plasticity.

W4095B Genetic suppression of basement membrane defects by altered function of the Myotactin/LET-805 receptor. *J. R. Gotenstein*, C. C. Koo, T. W. Ho, A. D. Chishom. University of California, San Diego, La Jolla, CA.

Basement membranes are evolutionarily ancient extracellular matrices that play key roles in tissue morphogenesis and organogenesis. In *C. elegans,* late embryonic development involves elongation of the embryo from a comma shape to a worm shape. Many basement membrane components such as type IV collagen and Perlecan are required for embryonic elongation. We previously showed that Peroxidasin/PXN-2 and F-spondin/SPON-1 are essential for epidermal elongation (Gotenstein, et al. *Development*. 2010; Woo, et al *Development*. 2008). Peroxidasins are extracellular peroxidases thought to catalyze sulfilimine cross-linking of collagen IV in the basement membrane. Complete loss of function of PXN-2 causes nonconditional lethality and arrest in late embryogenesis. F-spondins are conserved ECM proteins whose mechanisms remain unclear. We report that such *pxn-2* null mutant phenotypes can be suppressed to viability by gain of function mutations in a variety of extracellular matrix or cell-matrix receptor proteins. From large-scale screens for suppression of *pxn-2* or *spon-1* we identified over 30 suppressors, 12 of which result in missense alterations in the transmembrane protein myotactin/LET-805. The LET-805 extracellular domain contains at least 32 Fibronectin type III repeats (Hresko, et al. *JCB*. 1999); our suppressor mutations cluster in two pairs of repeats, suggesting these repeats may play a critical role in LET-805 function. *let-805* null mutants are nonconditional embryonic lethal; whereas our suppressors are viable and display no obvious phenotypes other than suppression. We find that *let-805* suppressor alleles partially suppress loss of function in other basement membrane components (type IV collagen) but not loss of function in intracellular epidermal cytoskeletal components (e.g. *vab-19*). Localization of a LET-805::GFP knockin is essentially normal in the suppressor alleles, suggesting they have a subtle effect on LET-805 expression. We will also present our analysis of additional suppressor loci from our screen. Our results reveal compensatory mechanisms in basement membrane receptor complexes that allow key structural or enzymatic components to be bypassed.

W4096C A regulatory genetic network in *C. elegans* embryos contributes to epidermal structural integrity during development. *M. K. Kelley*, D. S. Fay. University of Wyoming, Laramie, WY.

During development, biomechanical forces contour the body and provide shape to internal organs. We previously demonstrated that a regulatory network involving the conserved proteins SYM-3/FAM102A, SYM-4/WDR44, and MEC-8/RBPMS are required to maintain epidermal integrity in response to biomechanical forces in *C. elegans* embryos. Embryos and larvae that are doubly mutant for *mec-8; sym-3* or *mec-8; sym-4* have defective anterior morphology, called the Pharynx Ingressed or Pin phenotype. We showed that MEC-8 regulates the alternative splicing of multiple structural proteins including a fibrillin-like protein, FBN-1, which acts specifically in epidermal cells and is a component of the apical extracellular matrix (aECM or sheath). FBN-1 functions to withstand a variety of biomechanical forces acting on the epidermis, including an internally directed pulling force exerted by the pharynx as it undergoes stretch and elongation. Our current studies indicate that FBN-1 may attach directly to epidermal cells via integrins, which have not previously been reported to act within the epidermal aECM of embryos. Consistent with this, deletion of RGD (integrin-binding) sites in FBN-1 leads to induction of the Pin phenotype. In addition, mutations in *fbn-1*, *sym-3* and *sym-4* can enhance the "notched-head" phenotype (seen in integrin mutants) and inhibition of integrin subunits enhances Pin in *sym-3* and *sym-4* mutant backgrounds.

Our studies further indicate that SYM-3 and SYM-4 act in a parallel pathway to MEC-8 and may promote the trafficking of structurally important proteins in epidermal cells. Functional SYM-3 and SYM-4 fluorescent reporters localize to vesicle-like structures at or near the plasma membrane in epidermal cells. Furthermore, SYM-3 and SYM-4 act in a common genetic pathway with the RAB-11 GTPase, a known regulator of endocytic recycling and exocytosis, which has been shown to regulate integrin localization in other systems. Interestingly, *sym-4* is in an operon with *vha-20*/(ATP6-ap2/(P)RR, a multifunctional protein involved in vesicle acidification and planar cell polarity. Consistent with a previous study, we find that loss of *vha-20* perturbs RAB-11 localization and *vha-20(RNAi)* enhances Pin in *sym-4* mutants. In other studies, we have identified novel components of the aECM that function with FBN-1 to stabilize epidermal architecture during embryogenesis. We have also implicated roles for several cytoskeletal and cell-cell adhesion proteins in maintaining normal epidermal structure. Taken together, we have identified a network of genes that are required to maintain epidermal architecture in response to a variety of biomechanical forces during embryogenesis.

W4097A Axon guidance of the posterior lateral microtubule in *C. elegans* through VAB-1 activation by EFN-1. *E. M. Popiel*, I. D. Chin-Sang. Queen's University, KINGSTON, Ontario, CA.

Proper neural development is directed by numerous kinds of conserved axon guidance molecules, which includes a family of membrane-bound ligands and receptors called ephrins and ephrin receptor tyrosine kinases (EphRTKs). Previous research in the Chin-Sang laboratory has identified the EphRTK VAB-1 and its ephrin ligands EFN-1, EFN-2, EFN-3, and EFN-4 as key signaling molecules in the development of a pair of touch neurons in *C. elegans* called the posterior lateral microtubule (PLM) (Mohamed and Chin-Sang 2006). Loss-of-function *vab-1* mutants show a PLM overextension phenotype while constitutively active *vab-1* mutants show a strong premature termination phenotype in the PLM,

which suggests that activation of VAB-1 may play a key role in proper PLM termination during development. *efn-1* is the only ephrin ligand that shows a PLM overextension phenotype in the single loss-of-function mutant, although the triple *efn-2*; *efn-3*; *efn-4* loss-of-function mutant also shows a PLM overextension phenotype.

Since *efn-1* has the strongest PLM overextension phenotype of the ephrin ligands, we decided to investigate activation of VAB-1 by EFN-1 *in vivo*. Using ectopic expression of EFN-1 we have assessed its ability to activate the VAB-1 receptor to cause PLM termination when expressed on the same cell (*in cis*) and on neighboring cells (*in trans*). The ability of EFN-1 to activate VAB-1 to cause termination of the PLM axon both *in cis* and *in trans* in combination with our previous genetic analyses provides evidence that EFN-1 may activate VAB-1 *in vivo* to provide a stop cue for the PLM during development.

In addition to characterizing the activation of VAB-1 by EFN-1, we have also worked to identify the cellular location where the stop cue is produced to signal the PLM to halt its forward growth during development. We believe the source of the stop cue may be the seam cell V2, one of 10 specialized epithelial cells that run along the sides of the worm. This theory has been tested using genetic and molecular approaches, and our results indicate that there may be positional information exchanged between the PLM and V2, although more research is needed to clarify the nature of this interaction.

Our work adds to the current understanding of the role of EFN-1 in axon guidance in *C. elegans,* and the ability of epithelial and neuronal cells to communicate to facilitate development, and with further research this knowledge may be applied to human development.

W4098B Neurons and glia cooperate in assembly of the embryonic *C. elegans* nerve ring.. *G. Rapti*, S. Shaham. The Rockefeller University, New York, NY.

Central nervous system (CNS) assembly involves multiple cell-recognition events, including axon guidance and fasciculation. Despite extensive studies, how a connected brain emerges from these interactions remains enigmatic. Glia can act as guideposts for axon navigation, yet a detailed molecular understanding of this process is not currently at hand. To determine how pioneer neurons and glia cooperate to form a CNS, we are studying the assembly of the C. elegans CNS-like neuropil, the nerve ring (NR). The NR consists of ~170 axons and is enveloped and infiltrated by processes of four astrocyte-like CEPsh glia. CEPsh ablation does not result in neuronal death, allowing detailed investigation of glial roles in CNS assembly.

From a screen of fluorescent reporters expressed in subsets of embryonic neurons or glia we determined that the NR is populated in an orderly manner, with CEPsh extending processes early on, in conjunction with a small set of axons. Ablation studies reveal these pioneers are essential for NR entry insertion of diverse axons. We performed a forward genetic screen for mutants with NR entry defects resembling those in glia-ablated animals. In addition to known guidance factors, we isolated a new mutant that carries lesions in two genes, encoding a GTPase regulator and a pro-hormone convertase. Interestingly, each lesion alone results in only mild NR defects (5-15%); yet combining both lesions blocks 70% of NR entry of each of multiple neuron types. Importantly, full rescue of the double-mutant phenotype is achieved by combined expression of either gene in both pioneer neurons and glia. The mutant lesions result in defective axon guidance of pioneer neurons, they genetically interact with at least six known guidance pathways and they specifically affect intracellular trafficking of key guidance proteins. The synergistic nature of the double mutant, allowed us to perform screens for a novel class of axon-guidance mutants that function redundantly. We isolated over 20 such mutants, at least 14 of which appear to be in previously unknown genes. Our studies provide an inroad for studying CNS assembly in the light of neuron-glia communication and the complex redundancies of guidance pathways. Taken together, our findings suggest pivotal roles for glia in C. elegans CNS formation. This is highly reminiscent of roles of radial glia in the vertebrate brain. Furthermore, the mammalian homologs of the genes defective in our double mutant have known axon guidance roles in vertebrates, thus our studies will likely reveal conserved mechanisms promoting CNS assembly.

W4099C Novel reinforcement of Ras signaling by Rap1 in *C. elegans* vulval patterning. *N. R. Rasmussen*[1], D. Dickinson[2], D. Reiner[1]. 1) TAMHSC Institute of Biosciences and Technology, Houston, TX; 2) University of North Carolina, Chapel Hill, NC.

The small GTPase Ras is notorious as the most mutated oncoprotein in cancer. *C. elegans* and other systems were instrumental in defining the key components of Ras-Raf-MEK-ERK MAP kinase signaling cascade. However, the signaling activity of the small GTPase Ras is more convoluted than this. Decreased genetic redundancy and the anatomical simplicity of *C. elegans* provides an ideal setting to further dissect complicated Ras signaling during vulva cell fate specification. EGF induces Ras-mediated patterning of the six equipotent vulval precursor cells (VPCs) to generate the distinctive and highly reproducible pattern of 3˚-3˚-2˚-1˚-2˚-3 cell fates; presumptive 1˚ and 2˚ cells go on to form the vulva while 3˚ cells are non-induced and quiescent. Initial cell fate specification of the pattern is thought to be promptly followed by a reinforcement phase to enact final commitment, all prior to the first VPC division. We hypothesize that additional signaling mechanisms are executed to reinforce initial Ras-directed cell patterning and overcome contradictory signals within presumptive 1˚ VPCs. The small GTPase Rap1 (Ras proximal) is 100% identical to Ras in the core effector-binding region. Yet previous studies were inconclusive about Rap1 and Ras sharing effectors, particularly the S/T kinase Raf. Since *C. elegans* encodes a single Rap1 isoform that is not required for viability or fertility, we are using this system to define the role of Rap1 in the EGF-Ras signaling system. We N-terminally tagged endogenous Rap1 using CRISPR/Cas9. Tagged Rap1 localized to the plasma membrane of the six VPCs, consistent with published data of Ras promoter being active in VPCs, but providing more cell biological detail. Vulval-specific expression of mutationally-activated Rap1 was sufficient to hyper-induce VPCs. Consistent with Rap1 acting cooperatively with Ras, Rap1(RNAi) or deletion decreased 1˚ hyperinduction in a sensitized hyper-induced background. We also found that vulval-specific RNAi targeting the RapGEF, PXF-1, reduced hyper-induction, consistent with PXF-1 functioning to activate Rap1 in the vulva. We analyzed a transgenic transcriptional promoter::GFP fusion of the RapGEF, PXF-1. Prior to EGF signal, GFP was expressed at low levels in all six of the VPCs. After EGF signal, GFP expression was increased in presumptive 1˚ but decreased in presumptive 2˚ VPCs. Therefore, we hypothesize that Ras-Raf-MEK-ERK in presumptive 1˚ VPCs increases PXF-1 expression, and hence Rap1 activation, specifically in these cells

while Rap1 signaling is excluded from presumptive 2˚ VPCs. Thus the Ras-Raf signal is reinforced by a positive feedback loop. Our findings establish a novel aspect of Ras signaling, pointing the way to unconventional treatments for Ras-driven cancers.

W4100A Mechanosensing during *C. elegans* embryogenesis: Hunting for a putative mechanosensor. *S. Suman*, M. Labouesse. Institut de Biologie Paris-Seine, Paris, FR.

Mechanosensing refers to a process whereby mechanical inputs are sensed and transduced as a chemical or electrical signal to initiate or accelerate a downstream pathway. Many important biological events are mediated by this process including tissue differentiation, morphogenesis and also in pathophysiological conditions such as tumor progression, but their mechanisms at a molecular level remain poorly understood.

Mechanotransduction signaling *in vivo* can be triggered by body-wall muscle contractions (elongating *C. elegans* embryos), cell shape changes (*Drosophila* embryos), hydrodynamic forces (ventricle of mouse brain), or blood flow (heart development in zebrafish). During *C. elegans* development, embryos elongate 4-fold without additional cell division or migration. This process is highly robust and invariable. Previous studies demonstrated that hemidesmosomes (cell attachments to the extracellular matrix) play a critical role in mechanosensing by stabilizing the scaffolding protein GIT-1 in response to muscle input, but little is known about how it works at the molecular level (Nature, 2011 (471) 99-103). Therefore we aimed to characterize a putative binding partner of the earliest known effector (GIT-1) of mechanosensing. For this, we used both *in vitro* and *in vivo* (CRISPR-CAS9) tools to identify its binding partners (if any). Interestingly, we found that a core component of the hemidesmosome *i.e.*, VAB-10 strongly interacts with GIT-1 molecularly and genetically. Far-Western blotting suggests that purified VAB-10 and GIT-1 interact molecularly *in vitro*. Genetic interaction studies revealed that a mutation affecting the SH3 domain present within a spectrin repeat of VAB-10 strongly interacts with mutations in *git-1, pix-1* and also with *pak-1* (players of the mechanotransduction pathway). In double mutants background, embryos arrested prior to the two-fold stage, a phenotype also noticed in hemidesmosome-deficient embryos. This result suggests that the SH3 domain of VAB-10 provides an interaction platform for diverse players in response to physical cues in mechanosensing pathway. We would also like to extend our studies in the context of characterizing mechanosensing properties and molecular cause of such phenotypes using a combination of biophysical tools (AFM) *in vitro,* and genetic tools (transgenic line) *in vivo* respectively. Thus, understanding how mechanosensors and their signaling cascades operate should elucidate a cellular phenomenon in a better way.

W4101B A Genetic Screen for Temperature-Sensitive, Morphogenesis Defective Mutants in *C. elegans*. *Molly Jud*[1], Josh Lowry[1], Erin Clifford[1], Yuqi Yang[1], Hong Shao[2], Nhah Tran[2], Zhirong Bao[2], Bruce Bowerman[1]. 1) University of Oregon, Eugene, OR; 2) Memorial Sloan Kettering Cancer Center, New York, NY.

Embryonic morphogenesis in *C. elegans* is the process by which an ovoid mass of cells reshapes itself to take on the final elongated larval shape. Embryonic cells are quite dynamic during this process, undergoing both positional and morphological changes as they differentiate and form mature tissues. Many genes required for this dynamic behavior are also required earlier in development, complicating the identification of specific morphogenetic requirements using either non-conditional alleles or RNAi. Conditional alleles can bypass early genetic requirements and thus provide an excellent tool for dissecting later stage genetic pathways. We have isolated a collection of ~1,000 temperature-sensitive embryonic lethal (TS-Emb) mutants as a valuable resource for the identification of genes that influence embryonic morphogenesis. We now seek to identify all of the morphogenesis defective mutants within this collection, and to positionally clone as many of them as possible. In the longer term, we propose to build a systems-level model of embryonic morphogenesis.

To date, we have identified 68 mutants with penetrant embryonic morphogenesis defects. Most of these mutants arrest without extensive elongation, while others arrest after significant elongation (≥2-fold stage). We are initially classifying these terminal phenotypes using DIC microscopy. We also are scoring heterozygous embryonic lethality at the restrictive temperature and segregation frequency after outcross to ensure we are working with single gene, loss of function alleles. So far, nearly all alleles observed have behaved as expected for recessive, loss of function mutations.

We are using a high throughput whole genome sequencing-based approach to positionally clone mutants identified in this screen. This approach has been previously described[1,2] and applied to TS-Emb mutants affecting various stages of development[3,4], and both provides genome wide SNP mapping data and uncovers all homozygous SNPs within the mapping region. Genetic complementation tests against known loss of function alleles are then used to determine gene identity. So far, we have cloned 10 alleles representing 7 genes: *glp-1* (3 alleles), *let-19* (2 alleles), *klp-18, chaf-1, zwl-1, rib-1, hlh-1.* We anticipate that some of these genes will have direct roles in morphogenesis, while others may represent partial loss of function mutations in genes with earlier more general requirements in metabolism or cell division. Ultimately, we aim to clone 200+ mutants using this approach. These alleles will provide a resource that augments other efforts to build a detailed model of embryonic morphogenesis in *C. elegans*.

W4102C Male Specific Neurogenesis Depends on the Sexual State of the Seam in *C. elegans*. *Noah J. Reger*, Douglas S. Portman. University of Rochester, Rochester, NY.

In order to generate two functionally distinct sexes, sex-determination mechanisms must work in conjunction with generic developmental pathways to bring about unique changes in cellular differentiation and morphogenesis. How sex-determining factors generate dimorphic features from an otherwise identical cellular lineage is poorly understood. An example of this is ray neurogenesis in *C. elegans*. In males, the posterior seam cells give rise to neural precursors that generate rays, sensory organs required for mating. The DM gene *mab-3* and the Hox gene *mab-5* function in the male seam to activate the proneural gene *lin*-32, which triggers the ray sublineage. However, the activity of these genes does not appear to be restricted to males, making it unclear why ray neurogenesis is sex-specific. In order to better understand how the sexual identity of the seam affects ray neurogenesis, we used seam-specific promoters to drive expression of activators or inhibitors of the

master sex-determination regulator *tra-1*. This cell-autonomously "flips" the state of the sex-determination pathway, genetically reversing seam sexual identity. Interestingly, we found that masculinization of the hermaphrodite seam resulted in the development of ray neurons as well as a loss of alae formation in the posterior of the animal, indicating that "maleness" in the seam is sufficient to bring about ray neurogenesis. Masculinized hermaphrodites also displayed a mild tail retraction phenotype and appeared to form a male tail seam or SET cell. Surprisingly, these animals also have an exploding vulva phenotype, suggesting a possible role for seam sexual identity in vulva morphogenesis. Conversely, feminization of the male seam resulted in a significant loss of rays and the generation of ectopic alae as well as a reduced fan. Together, these data demonstrate that the sex-determination pathway functions in the seam to promote male specific neurogenesis. Using this sex-reversal strategy, we hope to identify how *tra-1* regulates gene expression in the seam to promote male-specific activation of *lin-32*.

W4103A Scaffolding Cells and Associated Molecular Factors in *C. elegans* Nerve Ring Development. *Kris Barnes*, Pavak Shah, Li Fan, Anthony Santella, Nhan Nguyen-Tran, Zhirong Bao. Memorial Sloan Kettering, New York, NY.

The embryonic development of the *C. elegans* nerve ring has remained an open and largely unexplored problem since John White mapped the nervous system in 1986. Genetic mutants with abnormal post embryonic nerve ring morphologies exist, but the specific cellular events in the developmental process and the function of associated molecular factors have not been well characterized. This is in part due to the difficulties involved with combining high resolution imaging with already time consuming forward genetic screens. We hypothesize a scenario where specific cells act as a scaffold to draw in surrounding axons and promote outgrowth along a concise and consistent path. This process must involve at least 3 main components: the development of the scaffold itself, local paracrine signaling which causes spatially separated axons to be drawn in to the scaffold, and a stage where cell specific juxtacrine factors promote the outgrowth of axons along specific paths. Initial anatomical observations point to several possible areas of interest which lie adjacent to the proto nerve ring including the GLR's, the pharyngeal primordium cells, and surrounding rows of neuroblasts which also lie parallel yet lateral to the incoming axon fibres. We aim to establish a functional relationship at the level of causation to determine which of these areas are involved in the scaffold. Furthermore, multiple incoming axon bundles are being studied for their spatial and temporal relation, and juxtacrine factors of interest are being identified with localized expression. We are finding specific genetic and anatomical perturbations leading to impairment of these processes, including results from mutant analysis and automated cell specific ablation experiments.

W4104B Dissecting *paired-box* and *odd-skipped* transcriptional networks. *Amy C. Groth*, Elizabeth J. Del Buono, Elizabeth A. Schoell, Gabriella M. Scoca. Eastern Connecticut State University, Willimantic, CT.

Paired-box (*pax*) and *odd-skipped* (*odd*) are two conserved families of developmental transcription factors. We are studying these two transcriptional families in *C. elegans*, in order to uncover genetic redundancies and functional interactions. In mammals, ODD proteins affect the development of a variety of tissues, including kidney, heart and soft palate, and are implicated in pancreatic and gastric cancer. Mammalian PAX proteins also affect the development of a wide variety of tissues, including palate and kidney. These two transcriptional pathways have been shown to interact in higher animals. Loss of function of *Odd* genes leads to altered levels of Pax2/8 in frog and mammalian kidneys. Mutation of *Pax9* and *Odd-skipped related 2* (*Osr2*) lead to cleft palate in mice, and PAX9 positively affects the expression of OSR2 in that tissue. *C. elegans* has 5 *pax* genes, *pax-1, pax-2, pax-3, egl-38 and vab*-3. Genetic interactions between *pax-2* and *egl-38* have been previously studied, but not between the remaining family members. Preliminary data shows that RNAi against *pax-3* increases lethality in a *vab*-3(*e1062)* mutant strain. It has been previously reported that knockdown of either *C. elegans odd* genes (*odd-1* or *odd-2*) leads to high levels of early larval lethality, due to defects in intestinal development. In our hands, an *odd-1*(*tm848*) mutant that deletes most of the gene or enhanced RNAi against *odd-1* do not result in high-level larval lethality. Fluorescent reporters of each *odd* gene (generous gift of the Rothman lab) show expression in adult posterior intestinal nuclei, with the brightest expression of ODD-1::GFP in Int9R. ODD-2 additionally shows strong expression in what appears to be the three rectal gland cells. RNAi against *odd-1* reduced the expression of ODD-2::GFP in the posterior intestinal cells, but not the rectal gland cells. Studies have been initiated to identify interactions between *odd* and *pax* in *C. elegans*. RNAi against the *pax* gene, *vab-3*, in an ODD-1::GFP strain resulted in variable brightness and number of GFP-expressing intestinal nuclei. This variability is consistent with a previous finding of a variable transgene expression phenotype found by RNAi against *vab-3*. RNAi against *pax-1* led to a slight deformity in the posterior intestine. Three *pax* genes have putative ODD binding sites in their promoters; experiments are planned to study the effect of *odd* mutants/RNAi on the expression of these genes.

W4105C The Transcription Factors LIN-31 and LIN-1 Play a Role in C. elegans Vulval Morphorgenesis. *L. M. Miller*. Santa Clara Univ, Santa Clara, CA.

The *C. elegans* hermaphrodite vulva is an ectodermal organ that connects the internal gonad with the external environment. Vulval morphogenesis involves cell-fate specification, cell adhesion, cell fusion, cell migration, and cell invasion. While much progress towards understanding signaling pathways has been made, an understanding of later morphogenetic events and how they are connected to cell fate specification is limited. The different fates of the six VPCs are determined in response to several extracellular signals and divide three times in a particular pattern to produce 22 descendants that begin as a linear array, then a tube, and finally a stack of seven toroids, with the anchor cell at the apex of this tube connecting to the uterus. The anchor cell then fuses to the utse uterine multinucleated cell, causing the opening of the tube. While the biochemical events that transduce the signal in the Ras/MAPK pathway are well characterized, it is ***not well understood*** how two transcription factors downstream of MAPK (LIN-31 and LIN-1) activate their downstream targets and play a role in vulval development. Specifically, the latter events (cell arrangements, invagination, toroid formation, cell migration, and cell-cell fusion events) are still ***not well understood***.

LIN-31 contains a winged-helix (WH) DNA-binding domain (DBD), a small acidic domain (AD), a putative MAPK D-domain docking site

(MAPKDS), four MAPK consensus phosphorylation sites (MAPK sites), and a homology region (RII). Site-directed mutagenesis revealed that the DBD, AD, and RII are important for LIN-31's function in vulval development. In addition, heterologous transcription assays in yeast indicated that that both the AD and RII function can act as transactivation domains. In contrast, we observed no measurable effect on LIN-31 function when we disrupted all four MAPK sites or the MAPKDS.

Since LIN-1 is also phosphorylated by MAPK during vulval development, we tested the effect of the loss of LIN-31 phosphorylation in a genetic background containing a point mutation in the LIN-1 MAPK docking site. In this ***sensitized*** genetic background, this mutation by itself does not display a strong Egl phenotype, however, when ***both*** LIN-31 and LIN-1 are defective for phosphorylation, we observe a ***strong Egl phenotype***. The identification of a sensitized background in which to study LIN-31 phosphorylation has also allowed us to identify a putative MAPK docking site on LIN-31, and preliminary confocal analysis of the *lin-31; lin-1* double phosphorylation-defective mutant suggests that the strong Egl phenotype is due to defective toroid formation.

W4106A Protein phosphatase 2A is crucial for muscle organization in *C. elegans*. *Hiroshi Qadota*[1], Yohei Matsunaga[1], William Vander Pols[1], Emily Swartzbaugh[1], Kristy Wilson[1], David Pallas[2,3], Guy Benian[1]. 1) Department of Pathology, Emory Univ, Atlanta, GA; 2) Department of Biochemistry, Emory Univ, Atlanta, GA; 3) Winship Cancer Institute, Emory Univ, Atlanta, GA.

Body wall muscle is fundamental for nematode locomotion. Among the more than several hundred proteins required for sarcomere assembly, maintenance and function, there are muscle specific giant proteins (>700 kDa). *C. elegans* has 3 giants; twitchin, UNC-89, and TTN-1. UNC-89 consists of 53 Ig domains, 2 Fn domains, 2 kinase domains, and KSP repeat sequence. UNC-89 is localized at M-lines, the structure in the middle of the sarcomere where thick filaments are cross-linked. Mutations in *unc-89* result in sarcomere disorganization (including absence of M-lines) and reduced locomotion. To understand how UNC-89 is positioned and how it carries out its functions, we are conducting a systematic identification of interacting molecules by using the yeast two-hybrid (Y2H) system, and have identified a number of interesting interactors (Gieseler et al. WormBook).

By using 1/3IK-Ig53-Fn2 region of UNC-89 as bait to screen a Y2H library, we identified PPTR-1 and PPTR-2. PPTR-1 and PPTR-2 are protein phosphatase 2A (PP2A) regulatory subunit B subunits (B56). A deletion mutant of *pptr-1, tm3103,* shows sarcomere disorganization. Anti-PPTR-1 antibodies localize to I-bands. Since antibodies generated to a highly conserved region of human B56 that is likely to react with both PPTR-1 and PPTR-2 stain I-bands and M-lines, we hypothesize that PPTR-2 may localize to M-lines. We also characterized muscle functions of other PP2A regulatory subunits. Antibodies to SUR-6 (B subunit)(provided by Kevin O'connell) localize to I-bands. A ts mutant of *sur-6*, *or550*, shows sarcomere disorganization at the restrictive temperature. Mutants of *rsa-1* (B'' subunit) display a characteristic myosin heavy chain A (MHC A) staining pattern. Normally, MHC A is located at the center of A-bands, localized as a straight single line. In *rsa-1* mutants, MHC A localizes as two parallel lines with the M-line in the center. Since some *unc-54* (MHC B) mutants (*s74*) show a similar split MHC A staining pattern, an RSA-1-associated PP2A complex might regulate phosphorylation of myosin heavy chains. The PP2A A subunit (PAA-1) and C subunit (LET-92) are also expressed in muscle. We addressed their muscle function by RNAi feeding from the L1 stage. Worms fed bacteria expressing *paa-1* or *let-92* dsRNA show muscle detachment from the basement membrane, resulting in folded "jack-knife" appearance. Taken together, protein dephosphorylation performed by PP2A might be crucial for many aspects of sarcomere assembly/maintenance.

W4107B CRISPR/CAS-9 mediated engineering of the *lin-3 egf* locus enables the analysis of tissue-specific functions. *S. Spiri*, L. Mereu, M. Morf, A. Hajnal. Universitiy of Zürich, Zürich, CH.

lin-3 encodes the only member of the epidermal growth factor (EGF) family in *C. elegans*. LIN-3 has a number of essential functions during larval development, hermaphrodite fertility and behavior. One of the best studied functions is the role of LIN-3 during primary (1°) vulval fate specification. After vulval induction, *lin-3* is also expressed in the inner-most 1° VulF cells to determine the uv1 subfate of cells in the ventral uterus. However, due to the many essential functions of *lin-3* during early larval development, it is difficult to detect potential later functions of LIN-3 after vulva induction. *lin-3* is a large locus with three different transcriptional start sites and many splice variants, making it difficult to create transcriptional reporters that reproduce the wild-type expression pattern. Using CRISPR/CAS9, we inserted an mNeongreen reporter into the *lin-3* locus to create an endogenous and fully functional LIN-3 reporter. This reporter has enabled us to analyze the expression pattern and subcellular localization of LIN-3.

Tissue-specific RNAi data has indicated that LIN-3 secreted by the VulF cells is required for dorsal lumen formation during vulval morphogenesis. To verify these RNAi data we generated a tissue-specific knockout strain by inserting into the *lin-3* locus two FRT recombination sites flanking part of the EGF domain. By expressing the *flp* recombinase under control of the heat-shock promoter we can now induce the loss of LIN-3 function at different developmental stages. In addition, we are expressing the *flp* recombinase under the control of different promoters to investigate the tissue-specific functions of LIN-3. This system will allow us to explore novel functions of LIN-3 in a highly specific manner.

W4108C Unearthing the cues to tissue identity within the gonadal sheath. *L. G. Vallier*, V. Tailor, M. Saini. Hofstra, Hempstead, NY.

A fertilized one-celled embryo contains all the genetic information to form the tissues and cells of the entire organism. Each division of the embryo results in a more restricted potential and a more specialized possibility for each of the two daughter cells to form a set of tissues and cells. In *C. elegans*, there are notably several master regulators of key cell fate decisions that have been well studied such as the Notch gene, *lin-12*, which for example, regulates the AC-VU decision to produce a wild-type vulva. More commonly, multiple genes act together in a combinatorial fashion to regulate the expression of a tissue or cell-type. In *C. elegans*, the gonad comprises two reflexed arms, each of which is mostly encircled by the gonadal sheath, a tissue composed of five pairs of cells. Gonadal sheath pair (Sh) 1 is necessary for maintaining the mitotically dividing stem cell population of the germline while Sh4 and Sh5 are necessary for ovulation of the mature oocytes into the

spermatheca. Loss of the sheath results in extremely reduced fertility: at most one – two progeny per hermaphrodite. Because of its simple structure we have used the gonadal sheath as a model to examine the genes that are required for establishment and maintenance of tissue identity. We approached our goal in several ways. First, using an RNAi screen to look for genes that were necessary for the presence or maintenance of the gonadal sheath, we uncovered approximately 40 candidate genes. Only one of these had been previously localized to the sheath. Next, approximately one-half of these candidate gene products are predicted to interact with gene products that have predicted or been shown to localize to the gonadal sheath. Finally, we used a datamining approach to look at unique expression patterns that have been reported in the literature. Approximately 246 genes have been reported to localize to or affect the gonadal sheath. After checking the literature and databases, only the localization pattern of 88 of the 246 genes could be confirmed in the literature and databases. Twenty-eight of those genes were not ubiquitously expressed in all five sheath pairs but had unique sheath pair expression patterns. Taken together, these data reveal potential new relationships of combinatorial gene expression patterns that begin to uncover signals that mark the identity of the gonadal sheath.

W4109A RNAi-based screens identify tube morephogenesis genes in the *C. elegans* spermatheca. *Md. Asaduzzaman Khan*[1], Fangyuan Wu[1], Rong Ying[1], Verena Gobel[2], Hongjie Zhang[1]. 1) Faculty of Health Sciences, University of Macau, Taipa, Macau, China; 2) Mucosal Immunology and Biology Research Center, MGH, Harvard Medical School, Boston, MA, USA.

Tubes are the building blocks of many internal organs in multicellular organisms, and defects in tube morphogenesis cause devastating diseases. To understand the molecular mechanisms of tube formation, our previous screen in *C. elegans* has identified hundreds of molecules required for tubulogenesis in intestine and/or excretory canals. Here in this study, we are aiming to identify genes involved in the formation and the size and shape regulation of a different tubular organ - the spermatheca - through a genome-wide RNAi screen.

The hermaphrodite spermatheca is composed of 24 epithelial cells organized into an accordion-like stretchable tube that contains sperm. Its ability to expand during the passage of oocytes demonstrates unique resilience and flexibility of a tubular epithelium. The spermatheca develops post-embryonically starting from late L3/early L4 stages, providing the following advantages for a tube morphogenesis screen: (1) it can be specifically targeted with conditional RNAi for those embryonic and larval lethal genes, conveniently bypassing their functions in growth regulation, signaling, transcriptional regulation, and cell fate determination; (2) it will help to recover non-lethal genes, whose knockdown may hardly affect the development of intestine and excretory canals; (3) its specific features may allow us to identify molecules involved specifically in tube resilience and flexibility, the characteristic existing in a number of human internal organs too.

The screen is designed to target non-lethal genes using standard RNAi condition and essential genes using conditional RNAi initiated after completion of embryogenesis on the *C. elegans* strains expressing distinct fluorescent markers that outline the structure of the spermatheca, such as LET-413, AJM-1 and ERM-1. Worms subjected to RNAi knockdown are first evaluated for morphological defects in gonad system under a dissecting fluorescence microscope followed by detailed characterization on spermathecal phenotypes by a confocal microscope. We are expecting to identify specific genes affecting spermatheca structure, size and shape etc. Here some preliminary results of our tube morphogenesis screen on the hermaphrodite spermatheca will be presented.

W4110B Developing an assay for high throughput detection of dauer larvae in *C. elegans*. *Maxwell Colonna*, Francesca V. Ponce, Goncalo Gouveia, Arthur S. Edison. Complex Carbohydrate Research Center, University Of Georgia, Athens, GA.

To enable NMR metabolomic studies in the model organism *Caenorhabditis elegans*, large-scale cultures are a prerequisite to produce small molecule extracts of sufficient concentration for analysis. Extensive growth results in a variable distribution in the distinct life stages of *C. elegans* (L1, L2, dauer, L3, L4, young adult and adult) that are present at any given time. The COPAS Biosorter, a specialized large particle flow cytometer, collects some phenotypic data of such cultures. While the sorter allows us to count and identify the normal developmental stages of sampled worms based on time of flight (TOF) and extinction (EXT) measurements, we cannot intuitively quantify how many dead or dauer worms result from these dense cultures. We treated samples with a fluorophore-conjugated lipid analog that has been previously shown to insert into the epicuticular layer of a normally developing nematode, but is excluded by dauer larvae. Combined with dauer-specific morphology data collected by the Biosorter, we are able to estimate the number of dauer worms present in a dauer "spiked" sample by calculating the number of non-fluorescent events that appear within the size and density range of dauer worms. This poster depicts our efforts to develop a robust, high-throughput assay for the presence of dauer larvae that utilizes the detection capabilities of the COPAS Biosorter to exploit biophysical and morphological differences between normally developing worms and dauer larvae. Along with fluorescent vitality dyes that can simultaneously identify the number of dead animals present in a sample, we aim to collect an inclusive set of phenotypic data from a single experiment that can be related to the resulting metabolite profile of each culture.

W4111C A developmental map of accessible chromatin in *C. elegans*. *Yan DONG*, Jürgen Jänes, Alex Appert, Djem Kissiov, Julie Ahringer. The Gurdon Institute, University of Cambridge, Cambridge, UK.

Genome-wide mapping of regulatory regions is important for understanding developmental gene regulation. Regulatory elements such as promoters and enhancers are often nucleosome-depleted, rendering them accessible to digestion by a low concentration of DNase I. Regions of open chromatin are also susceptible to transposition of sequencing adaptors by the transposase Tn5 (ATAC-seq). Nucleosome occupancy or positioning can be mapped by digestion using MNase. In *C. elegans*, chromatin accessibility data is currently limited to a single stage generated using DNase-chip whereas MNase maps are only available for two developmental stages.

We have used ATAC-seq, DNAse-seq, and MNase-seq to map genome-wide accessibility at six developmental stages: embryos, four larval stages and young adults. Using ATAC-seq, we define more than 30,000 accessible sites across development, which show agreement with developmental TF ChIP binding patterns from the modENCODE project. Most accessible sites are present at multiple stages, with stage specific

sites primarily occurring in embryos and young adults.

Although many accessible sites are detectable at multiple stages, the majority of sites change in accessibility across development. We observe two common patterns of developmental changes — regions that decrease over development and regions that increase over development. Regions with increasing accessibility are characterised by lower G+C content compared to regions with decreasing accessibility. We further characterise regions of open chromatin based on relative accessibility to DNase I, nucleosome occupancy, transcription factor or chromatin remodeller binding, and histone modifications.

W4112A CEC-4 reads histone H3K9 methylation to promote heterochromatin organization. *Jennifer C. Harr*[1], Adriana Gonzalez-Sandoval[1,2], Daphne S. Cabianca[1], Susan M. Gasser[1,2]. 1) Friedrich Miescher Institute for Biomedical Research, Basel, Switzerland; 2) Faculty of Natural Sciences, University of Basel, Basel, Switzerland.

Heterochromatin is localized at the nuclear periphery in most eukaryotic organisms. A distinct compartmentalization of euchromatin and heterochromatin occurs upon cellular differentiation. The functional relevance of sequestration of chromatin at the nuclear periphery is unknown. While a variety of studies have begun to identify factors involved in anchoring chromatin at the nuclear periphery, the functional characterization of this mechanism, particularly in differentiated tissues, has yet to be described. In *C. elegans* embryos, we have identified the histone H3K9 methylation reader CEC-4 as a factor that maintains chromatin positioning at the nuclear periphery. CEC-4 binds selectively histone H3 bearing mono-, di- or tri-methylation on lysine 9 and is localized independently of chromatin to the nuclear periphery. In *cec-4* mutant strains the anchoring of chromatin is perturbed both for an integrated heterochromatic array and for endogenous chromosomes, although gene expression is not affected. Beyond larval stages, additional anchoring pathways compensate for the loss of CEC-4. We carried out a forced muscle cell transdifferentiation assay by heat-shock induction of the MyoD homologue, HLH-1, to address the function of reduced anchoring in early embryos. *cec-4* mutant embryos had the ability to continue developing into a larva-like stage, unlike the wild-type embryos. Therefore, we propose that the anchorage of chromatin at the nuclear periphery in early *C. elegans* embryos helps to stabilize cell fate decisions.

CEC-4 is expressed throughout development with variable expression levels across differentiated tissues and muscle cells in larvae and adult worms. Muscles exhibit particularly high levels of CEC-4. Live cell imaging of *cec-4* mutants harboring a heterochromatic reporter suggests that CEC-4 contributes to chromatin anchoring in differentiated muscle and gut cells. H3K9 methylation has been implicated in nuclear organization across species, although CEC-4 is not conserved. We are currently investigating the additional mechanisms that tether chromatin to the nuclear periphery in order to find other factors that are involved. RNAi of all known nuclear envelope proteins in worms, individually and in pairwise combinations, did not disrupt CEC-4 localization. Mutations that act synergistically with CEC-4 to delocalize chromatin include other histone modifying enzymes and readers. We are currently exploiting BioID (proximity-dependent biotin identification) to screen for protein- protein interactions of CEC-4 to characterize its role in perinuclear anchoring throughout development.

W4113B In search of *C. elegans* histone H3 lysine 27 methylation (H3K27me) 'readers'. *Arneet L. Saltzman*[1,2], Mark W. Soo[1], Jeannie T. Lee[1,2,3]. 1) Department of Molecular Biology, Massachusetts General Hospital; 2) Department of Genetics, Harvard Medical School; 3) HHMI.

The Polycomb group proteins form chromatin-modifying complexes that function in the inheritance of gene expression patterns. Originally identified in *Drosophila* for their role in body patterning through Hox gene repression, Polycomb group proteins act in part through repressive modifications to the N-terminal tails of histones. In particular, methylation of lysine 27 on histone H3 (H3K27me) can be recognized or 'read' by the chromo (chromatin organization modifier) domain, found in the *Drosophila* Polycomb and related mammalian Chromobox proteins. Previous work has shown that H3K27me is important for germ cell fate and worm development, yet a 'reader' of this mark in *C. elegans* has remained elusive. Several *C. elegans* genes have been identified by the sequence similarity of their encoded chromodomains to those of Polycomb and Chromobox proteins (Agostoni *et al*. 1996), however the binding preferences of these chromodomain-containing factors are not known. To determine whether these candidates have specificity for methylated histone tail residues, we are using a biochemical approach in which recombinant proteins are assayed for binding to a panel of histone tail peptides. To understand the potential roles of these proteins in development and chromatin modification pathways, we are creating knockout and tagged knock-in strains that will allow us to identify the genomic binding sites and protein interaction partners of these proteins by ChIP-Seq and mass spectrometry, respectively. Our results suggest that the *C. elegans* genome encodes several chromodomain 'readers' of histone H3K27 methylation. Uncovering the degree of functional overlap versus cell type or target locus-specificity among these related factors may provide an informative model for the regulatory complexity also observed in mammalian chromatin modification readers.

W4114C TGF-β signaling promotes competence for sleep in *C. elegans*. *D. Goetting*, C. Van Buskirk. California State University Northridge, Northridge, CA.

Members of the transforming growth factor beta (TGF-β) family of secreted factors play critical roles in development across species. In the nematode *C. elegans*, the DAF-7/TGF-β ligand is part of a signaling cascade that determines developmental, metabolic, and behavioral decisions based on environmental conditions. During larval development, favorable environmental conditions activate a conventional TGF-β signaling cascade that promotes reproductive growth by stimulating the production of a hormone, dafachronic acid (DA). In the absence of this signal, the animal delays reproduction and growth by entering into an alternate life stage known as dauer. In addition to its roles during development, TGF-β signaling has known roles during the adult stage, including pathogen avoidance and longevity. Here, we describe a previously unknown physiological role for TGF-β signaling in sleep behavior. *C. elegans* is known to sleep following exposure to noxious environmental conditions that cause cellular stress, such as heat. This stress-induced sleep (SIS) response is mediated by activation of epidermal growth factor (EGF) signaling in a sleep-inducing neuron called ALA, and induction of EGF-overexpression (EGF-OE) promotes a

robust sleep response in the absence of noxious stress. We have identified that *daf-7*/TGF-β mutants are impaired for SIS, and intriguingly, that various aspects of the sleep program are differentially affected. By exposing *daf-7* mutants to a variety of stressors and examining their sleep behavior, we have determined that *daf-7* mutants are severely impaired for locomotor quiescence but only mildly impaired for feeding quiescence. We wished to ascertain where in the SIS pathway DAF-7 is acting. To test this, we overexpressed the EGF ligand and examined *daf-7* mutants for sleep behavior. Interestingly, we found that *daf-7* mutants are still slightly impaired for sleep in response to EGF-OE. This suggests that the primary effects of DAF-7 on SIS may be downstream of EGF. To determine whether the role of DAF-7 in sleep regulation is dependent on DA hormone signaling, we examined *daf-36* and *daf-12* mutants, which are defective in the production of DA and its receptor, respectively. Both mutants displayed very mild defects in SIS, indicating that the effects of DAF-7 are attributable partially to dafachronic acid production during development and partly to an unidentified mechanism. I am currently analyzing changes in *daf-7* expression in response to stress. We speculate that DAF-7 may be conferring competency on the ALA neuron to mediate discrete aspects of EGF-induced sleep. Therefore, I plan to analyze reporter genes corresponding to ALA-expressed components of stress-induced sleep.

W4115A Optogenetics of gene regulation in *C. elegans*. *A. K. Lam*, K. Dvorak, V. Prahlad, B. T. Phillips. University of Iowa, Iowa City, IA.

Precise spatial and temporal activation of target genes at specific tissues or cells are critical in the study of developmental processes in vivo. Currently, various chemical and genetic methods of gene activation used in nematodes lack precise spatiotemporal specificity. We adopted a light dependent gene activation system for a more precise and controlled gene activation. Using light-sensitive protein dimerization of *Arabidopsis* cryptochrome 2 and the bHLH protein CIB1, the CRY2-CIB system activates gene expression through the interaction of two fusion proteins, CRY2-LexA DNA binding domain and CIB-VP16. In the presence of blue light, the two fusion proteins bind and activates the transcription of target genes under the LexA promoter. To track activation of target genes, we created a LexA activated target gene followed by SL2 splice site linked to mCherry florescent reporter. Preliminary results showed positive target gene activation in transgenic following a global exposure of blue light. Further studies will be done to observe target gene activation in a tissue specific manner in various nematode developmental stages.

W4116B Modeling Craniofacial Diseases in *C. elegans*. *Aditi Chandra*[1], Tyler Hansen[1], Sharon Kim[1], Victoria Scanlon[2], Andrew Wilkie[3], Ann Corsi[2], Andy Golden[1]. 1) NIDDK/NIH, Bethesda, MD; 2) The Catholic University of America, Washington, DC; 3) University of Oxford, Oxford, UK.

Millions across the world are currently living with one of 7,000 rare diseases, the majority of which are thought to be monogenic in origin. Due to their rarity, many of these diseases are not well studied. As a result, patients with a monogenic disease often face limited treatment options and a slim chance towards remission. However, with recent advances in genome editing, it is now possible to model many inherited diseases in a variety of organisms. Given this, we are utilizing *Caenorhabditis elegans* as an avenue to model monogenic diseases and develop treatments for patients. The nature of *C. elegans* makes it an efficient, inexpensive, and simple system to accomplish this task. In this study, we have applied this novel approach to explore Barber-Say, Ablepharon Macrostomia, and novel Saethre-Chotzen-like syndromes, which arise due to mutations in the two human TWIST genes. These syndromes are autosomal dominant in nature. We use *C. elegans* to model conserved mutations in *hlh-8,* the TWIST ortholog.

Human TWIST1 and TWIST2 are bHLH transcription factors involved in many important pathways, including craniofacial development. As a result, humans with TWIST dysfunction have severe bone development defects, most obvious in the skull manifested as craniofacial deformation. Using our system, we modeled six mutations found in patients with the above three syndromes. The mutations, all at codon 29 of *hlh-8*, disrupt the basic domain, which binds DNA. Interestingly, we observed different, distinct phenotypes for each allele, even though these mutants only differed by the amino acid at codon 29. The three phenotypes we observed were one or a combination of the following: egg-laying defective (Egl), constipation (Con), and a tail deformation. The most severe allele exhibited all three phenotypes whereas the mildest only displayed an Egl phenotype. Medium severity alleles exhibited an Egl phenotype with a variably penetrant Con and tail deformation phenotype. This unexpected spectrum of alleles poses some interesting biochemical questions for future investigation. A previously studied null *hlh-8* mutation behaved as a recessive allele with all three of these phenotypes. Our genetic analysis is consistent with these new alleles having a dominant negative nature, which suggests the human syndromes are due to defective TWIST proteins interfering with wild-type TWIST function. Future plans include suppressor screens of these alleles and modeling other diseases using this methodology.

W4117C Genome engineering with the CRISPR/Cas9 system in *C. elegans*. *Daniel J. Dickinson*, Bob Goldstein. Department of Biology and Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC.

The CRISPR/Cas9 system is fast becoming an indispensible tool for research in model organisms, including the nematode *C. elegans*. In just the past few years, a large number of different strategies for CRISPR in *C. elegans* have been described. The purpose of this presentation is to aid users in choosing the most effective strategies for their applications. We will summarize our own contributions to genome editing techniques for the worm, along with the work of others, and provide recommendations for which approaches to try first for different types of genome modifications. In addition, we'll present some novel applications and improvements to our selection-based protocol (Dickinson et al. 2015), including improved cloning methods, a streamlined approach for structure-function experiments, and a conditional balancer strategy that facilitates functional studies of essential genes.

W4118A Recombineering in C. elegans: genome editing using in vivo assembly of linear DNAs. *A. PAIX*, H. Schmidt, G. Seydoux. HHMI - Johns Hopkins University School of Medicine, Baltimore, MD.

Recombineering, the use of endogenous homologous recombination systems to recombine DNA in vivo, is a commonly used technique for genome editing in microbes. Recombineering has not yet been developed for animals, where non-homology-based mechanisms are thought

to dominate DNA repair. Here, we demonstrate that in C. elegans, linear DNAs with micro-homologies (35 bases) participate in a robust local gene conversion mechanism that can be exploited for recombineering. We find that double-stranded PCR amplicons and bridging single-stranded oligonucleotides (ssODNs) recombine readily to form novel DNA assemblies in vivo that can repair double-strand breaks induced by CRISPR/Cas9 on chromosomes. We use this method to create precise GFP knock-in alleles using a universal linear GFP template and two gene-specific "bridge" ssODNs linking GFP to the Cas9 cleavage site. In vivo assembly can also be used to assemble novel knock-in fusions and gene replacements, and is efficient enough for use without selection (scarless edits). Our findings are consistent with the budding yeast models for synthesis-dependent strand annealing and template switching during repair-induced DNA replication. We conclude that, like microbes, metazoans possess robust homology-dependent repair mechanisms that can be harnessed for recombineering and genome editing.

W4119B Digital resources for high-throughput analysis of 3D spatial and temporal cell division dynamics in early embryos. *K. Kyoda*, H. Okada, S. Onami. RIKEN Quantitative Biology Center, Kobe, JP.

During animal development, cells are genetically controlled to generate the three-dimensional morphological structures. A collection of quantitative data of spatiotemporal morphological dynamics when a wide variety of individual genes are perturbed would provide a rich resource for understanding animal development. Here we created a collection of quantitative data of cell division dynamics in early *C. elegans* embryos when each of all 351 essential embryonic genes was silenced individually by RNA interference (RNAi). To collect five sets of quantitative data from RNAi-treated embryos for each gene, we applied our computer image processing system to ~2,000 sets of four-dimensional differential interference contrast microscopy images. The collection finally consists of 33 sets of quantitative data for wild-type embryo and 1,142 sets of quantitative data for RNAi-treated embryos for 243 genes. Each data contains the 3D coordinate values of the outlines of nuclear regions and the changes of the outlines over time. We first performed computational phenotype analysis by using this collection. Statistical analysis identified over 6,000 RNAi-induced phenotypes for 437 phenotypic characters, which can be numerically extracted from the collection. The phenotypes include three-dimensional (3D) spatial and temporal phenotypes that are difficult to be identified manually. We next predicted sets of genes involved in the same cellular processes from the collection. By applying hierarchical clustering method to the profiles of the extracted phenotypic characters, we found 7 independent clusters corresponding to the individual cellular processes such as polarity/asymmetric division, DNA replication and chromosome maintenance/segregation. In addition, we developed novel computational methods for inferring a coarse-grained model of embryogenesis by finding correlations between phenotypic characters. The inferred model represents the order in which the phenotypic characters relate and appear in the course of development. Our collection provides novel opportunities for performing high-throughput analysis of 3D spatial and temporal cell division dynamics during animal development. In the near future, all data and results will be available at the Worm Developmental Dynamics Database (http://so.qbic.riken.jp/wddd).

W4120C SSBD: an open database of quantitative data and microscopy images of biological dynamics. *Y. Tohsato*, K. Ho, K. Kyoda, S. Onami. RIKEN Quantitative Biology Center, Kobe, JP.

Recent technological advances in digital microscopy and image analysis have produced a large amount of quantitative data of spatiotemporal dynamics of biological objects such as molecules, cells, and organisms. These quantitative data can be used to reveal the nature of dynamical behaviors of biological phenomena. However, these data are difficult to reuse for further analysis because they are often scattered over the Internet in different formats. There is a crucial need in bringing these data together in a coherent and systematic manner. We developed Systems Science of Biological Dynamics database (SSBD) as an open repository for quantitative data and microscopy images (http://ssbd.qbic.riken.jp). SSBD provides quantitative data in a unified format (BDML: Kyoda *et al.*, 2015) and through REST API (Representational State Transfer Application Programming Interface). SSBD also provides image data in the original format by using OMERO platform. SSBD currently provides 313 sets of quantitative data and 194 sets of microscopy images for single molecules, nuclei, and whole organisms in a wide variety of model organisms from *E. coli* to mouse. For example, SSBD includes 186 sets of nuclear division dynamics data of wild-type and RNAi-treated *C. elegans* embryos during the first three rounds of cell division and the corresponding 4D differential interference contrast microscopy images. One set of nuclear division dynamics data of wild-type *C. elegans* embryo from 4- to 350-cell stage, and 11 sets of behavioral dynamics data of goa-1 *C. elegans* adults are also included. A web-based viewer allows users to visualize quantitative data in time and 3D space on-demand without any additional plugin. In addition, SSBD provides software tools for data visualization and analysis such as Phenochar and BDML4DViewer. Phenochar is a software tool for extracting phenotypic characteristics from the data in BDML format. BDML4DViewer is an ImageJ plugin to read and visualize quantitative data in BDML format. The open-source version of SSBD for managing quantitative data is also available at http://github.com/openssbd/. It enables other research groups to setup their own databases independently for storing and sharing their data. SSBD will support data-driven biology by accelerating the reuse of quantitative data and microscopy images, and development of software tools for data analysis.

W4122B Calcium imaging of a dopamine-regulated chemosensory circuit in *Caenorhabditis elegans*. *C. Kunkel*, J. Kim, M. Baidya, P. Turturro, M. Chao. California State University San Bernardino, San Bernardino, CA.

The neurotransmitter dopamine regulates chemosensory avoidance behavior in the model organism *Caenorhabditis elegans*. Avoidance behaviors are mediated by the polymodal ASH nociceptive sensory neurons, and behavioral avoidance of stimuli detected by ASH is less robust when dopamine signaling is impaired. Our broad research goals are to understand the underlying molecular and cellular mechanisms of how dopamine modulates the activity of neural circuits. Using a custom microfluidics device and the transgenically-expressed Ca^{2+} sensor GFP variant G-CaMP, we have begun to characterize the ASH neural response of wild type and dopamine-deficient *cat-2* mutant *C. elegans* when

treated with exogenous dopamine and stimulated with the osmolyte glycerol. Our preliminary data suggest that exogenous dopamine perfused into the recording buffer in the microfluidics device affects ASH neuron excitability in *cat-2* mutants. Our ongoing efforts now focus on optimizing our assay conditions (including type of stimuli to use and recording buffer components) and identifying molecular elements in ASH neurons that mediate this response, including the relevant dopamine receptor(s).

W4123C Differential Gene Expression within a Single Sex-Specific Class of *Caenorhabditis elegans* Neurons. *D. K. Reilly*[1], E. M. Schwarz[2], J. Srinivasan[1]. 1) Worcester Polytechnic Institute, Worcester, MA; 2) Cornell University, Ithaca, NY.

Organisms must be able to accurately assess a constantly changing environment as they navigate their surrounding – avoiding danger, remaining in beneficial areas, and determining whether or not a potential mate is in the vicinity. *C. elegans* males sense nearby hermaphrodites through pheromones of the ascaroside family of small-molecule social cues. The sex-specific ascarosides, namely ascarosides #3 and #8, are sensed via the male-specific CEM neurons. Laser cell ablation studies have confirmed that the CEM neurons are necessary and sufficient for sensation of ascaroside #8, whereas ascaroside #3 sensation requires ASK neurons as well. While the four CEMs are considered to be of a single class of neurons, recent work has shown that individual CEMs respond uniquely to these cues (Narayan et al, 2016). The neurophysiological properties of these individual neurons are stereotyped, yet summation of the four CEMs suggests a heterogeneous response to ascarosides #3 and #8. To understand the molecular mechanisms of these differences in response to the stimuli, we isolated transcriptomes from each of the four individual CEM neurons. We then performed RNA-seq analysis to determine genes with elevated expression levels in these sex-specific sensory neurons. We created GFP-promoter fusions to confirm expression within a single CEM neuron for each gene. We identified five potential receptor candidates necessary for sensing the two ascarosides using the CEM transcriptomic data and gene ontology analysis. We intend to extend these findings to manipulate individual CEM neurons with optogenetic tools to dissect how they communicate with each other to drive male behavior.

W4124A High throughput chemical genomics in *C. elegans* to screen for novel bioactives and their targets. *H. Zahreddine Fahs*, F. Refai, R. White, PG. Cipriani, S. Kremb, F. Piano, KC. Gunsalus. New York University Abu Dhabi, Abu Dhabi, UAE.

Biologically active chemicals are the basis of most known therapeutics and are powerful tools to study cell biological processes. However the discovery of new bioactive compounds and characterization of their molecular targets remain a challenge. We are using small molecule and natural products libraries to identify novel compounds that affect animal development and study their modes of action. We have established a high-throughput automated platform for chemical and functional genomic screening that accommodates both cell-based and whole-organism (e.g. microbial, worm and zebrafish) assays. We are focusing on potential disease therapeutics (e.g. cancer, diabetes) and broad-spectrum anthelmintics (to target parasitic nematodes that affect human, crops, and livestock) using the free-living nematodes *C. elegans* and the distantly related *P. pacificus* as model animals, since they offer a rapid and powerful platform for lead compound discovery and mode of action studies. Given the short life cycle of the worm, our high-throughput screening (HTS) platform enables one person to screen 20,000 chemicals per week and perform one genome-wide RNAi screen every 2 weeks. Results are scored using automated image analysis with DevStaR, a software package we developed that employs computer vision and machine learning to quantify embryonic lethality in mixed-stage worm populations (*White et al., 2013*). We validated our screening approach in a pilot screen of an FDA-approved drug library, which confirmed the effects of known anthelmintics on *C. elegans* and *P. pacificus*. We then screened a library of ~32,000 small molecules that were selected using a computational approach to predict bioavailability in nematodes (*Burns et al. 2010*). Preliminary analysis based on worm survival and developmental phenotypes suggests a 4% hit rate. Positive hits will be assayed for toxicity in zebrafish and mammalian cells. To uncover molecular targets of bioactives and mechanisms of resistance, we will use forward and reverse genetic screens to identify suppressors (or enhancers) of chemical sensitivity. We are also performing chemical screens using sensitized *C. elegans* genetic backgrounds to identify molecules that specifically interact with targeted pathways. In parallel, we screened a library of 300 uncharacterized *Bacillus thuringiensis* (Bt) strains (isolated by Mireille Kallassy – USJ, Lebanon). Bt is a spore-forming bacterium that synthesizes crystal inclusions, some of which are toxic against insects (used as bioinsecticides), nematodes and cancer cells. These crystal proteins are safe to humans, biodegradable, and constitute a promising alternative to chemical anthelmintics. We found 95 Bt strains that hinder the development of *C. elegans* or *P. pacificus* and are analyzing these to characterize new virulence factors and mechanisms of action.

W4125B Ribosomal DNA copy number as an unexplored potential source of heritable phenotypic variation. *E. Morton*, C. Mok, S. Lee, R. Waterston, C. Queitsch. University of Washington, Seattle, WA.

Complex phenotypes such as lifespan, disease susceptibility, and mutation penetrance vary substantially even among isogenic individuals. The molecular determinants behind this variation have long been sought, along with the ability to predict how one individual will differ from another. In *Caenorhabditis elegans*, variation in lifespan and mutation penetrance among nominally isogenic individuals has recently been linked to differences in expression of molecular chaperones. These expression differences are heritable, implying a stable epigenetic or unstable genetic source. We propose copy number variation in ribosomal RNA genes as an underlying, unexplored genetic cause of phenotypic variation. Ribosomal RNA genes (rDNA) exist as tandem gene arrays in all eukaryotes, and their repetitive nature predisposes them to instability and thus copy number variation among individuals. Differences in rDNA copy number indeed exist among laboratory N2 worms only ten generations removed from a common ancestor. rDNA copy number is known to associate with global gene expression in flies and humans. rDNA also associates with genome integrity and replicative lifespan in yeast. Furthermore, the nucleolus itself, which is comprised of rDNA, is a major hub of stress response and protein homeostasis. Despite its obvious biological significance, rDNA and its copy number variation are understudied, due largely to the inherent technical challenges involved in genotyping repetitive DNA. We have addressed this problem by developing a high-throughput technology to genotype rDNA copy number in *C. elegans*, employing molecular inversion probes to count repeat

units. This cost-efficient and universally applicable method provides rDNA copy number estimates that agree with whole genome sequencing-based estimates. Facilitated by this technology, we have begun exploring the potential phenotypic consequences of rDNA copy number variation. Our preliminary data show an association between rDNA copy number and two different biomarkers of longevity. Our results suggest that rDNA copy number may be a contributor to phenotypic variation among nominally isogenic individuals. We provide a technology to make this class of genetic variation accessible for in-depth exploration of the phenotypic consequences of rDNA copy number variation in *C. elegans* as well as for future studies of aging and disease susceptibility in other organisms, including humans.

W4126C Textpresso: mining full text for efficiently obtaining information from the biological literature. *Paul Sternberg*[1], Hans-Michael Müller[1], Yuling Li[1], Kimberly Van Auken[1], Christian Grove[1], Karen Yook[1], Ranjana Kishore[1], Seth Carbon[2], Chris Mungall[2], Suzanna Lewis[2]. 1) Division of Biology and Biological Engineering, California Inst of Technology, Pasadena, CA; 2) Genomics Division, Lawrence Berkeley National Lab, Berkeley,CA USA.

We all face a continual increase in the number of papers whose content we need to know. Curators at biological databases such as WormBase also need to efficiently locate and extract information from this expanding corpus of papers. To help reduce the tedium and cost of scouring the literature for specific experimental results, we developed the Textpresso text mining system available at www.textpresso.org. We have completely rewritten the system to scale to millions of papers (e.g., all of PubMedCentral) and to help biocurators at the model organism databases and the Gene Ontology Consortium (GOC) make annotations to genes, cells, molecules and so forth. Textpresso indexes individual sentences with keywords and categories of terms that allow highly specific searches. Category searches in *C. elegans* Textpresso allow you to find all sentences in any *C. elegans* paper that mentions, for example, a worm gene and a human disease, or a drug, a cell type and a phenotype. Textpresso also indexes the Drosophila, mouse, zebrafish and yeast literature. We are now integrating the new system (TextpressoCentral) into the GOC's Common Annotation Framework. This framework was designed to work for all biological literature and allows annotation using the Noctua curation tool developed to support GO's more expressive LEGO curation paradigm, which relates gene products to specific functions in context. We will explain the use of Textpresso for individual researchers and for biocurators, and howTextpresso will make your life better by making it much easier to find particular information quickly. For example, by automating the process of skimming thousands of papers for some detailed information, Textpresso will allow you to spend more time reading papers.

W4127A Metablomics meets genomics in *Pristionchus pacificus*: A highly specific esterase is involved in the synthesis of dauer inducing small molecules. *J. M. Meyer*[1], N. Bose[2], J. Y. Yim[2], A. Artyukhin[2], F. C. Schroeder[2], R. J. Sommer[1]. 1) Max-Planck Institute for Developmental Biology, Tuebingen, DE; 2) Boyce Thompson Institute, Cornell University, New York, USA.

All animals have evolved abilities to react towards changes in their environments. Nematodes for example, can arrest their development under adverse environmental conditions and enter a long-lived, stress-resistant "dauer" stage. This "dauer stage" plays a major role as survival but also as dispersal strategy of nematodes. Small molecules are crucial for the regulation of dauer entry and additionally, have been shown to function as cues in chemical communication through which they can regulate complex behaviors. Recent studies in *Pristionchus pacificus* and comparison to Caenorhabditis *elegans* indicated that small molecule structure and function evolve rapidly. One hallmark is that small molecule structures in *P. pacificus* are far more complex than their *C. elegans* analogs. Also, the collection of worldwide isolates of *P. pacificus* provided strong evidence for extreme natural variation of these pheromones across genotypes. In this context, a new type of intraspecific competition among sympatric strains was identified with a new role of small molecules in nematode evolutionary ecology. Thus, small molecules are important for the regulation, ecology and evolution of dauer development. Despite this, very little is known about the enzymes and pathways involved in the synthesis of small molecules. Here, we study intra-species variation in small molecules production in *P. pacificus* on La Réunion Island. In the last 5 years, we extensively sampled a nematode population by collecting more than 300 local strains, which were subsequently characterized through a combination of genomic (RAD-sequencing) and secrotomic (HPLC/MS/MS) approaches. We found that these highly related strains still showed massive differences in their small molecule secretomes. Most importantly, ubas#1 and ubas#2, two compounds shown to play a crucial role in dauer regulation, were absent from a certain number of strains. Combining both datasets we were able to utilize genome-wide association studies (GWAS) to identify a candidate region. Using nanopore and whole genome re-sequencing we confirmed the identity of the causative gene as a putative esterase that is involved in the synthesis of ubas#1 and ubas#2. We used the CRISPR/CAS9 system to inactivate the esterase-encoding gene and found the resulting mutant to be ubas#1 and ubas#2 deficient. Thus, through a multifaceted experimental approach we have identified a key enzyme involved in the synthesis of complex, dauer-inducing small molecules in *P. pacificus*.

W4128B *Caenorhabditis* sp. 34 is a sister species to *C. elegans* with marked differences in morphology and ecology. *A. Sugimoto*[1], R. Tanaka[2], K. Tsuyama[1], S. Namai[1], R. Kumagai[1], T. Shimura[1], N. Kanzaki[3], T. Kikuchi[2]. 1) Tohoku University, Sendai, JP; 2) University of Miyazaki, Miyazaki, JP; 3) Forestry and Forest Products Research Institute, Tsukuba, JP.

For comparative and evolutionary studies, satellite species that are closely related to established model organisms are valuable. In the genus *Caenorhabditis*, several species (e.g., *C. briggsae*, *C. brenneri* and *C. remanei*) have been used as satellite models for *C. elegans*, but no phylogenetic "sister" species to *C. elegans* has been isolated. Recently we discovered a new species *Caenorhabditis* sp. 34 from syconia (fresh fruits) of the fig *Ficus septica* in Ishigaki Island, Japan. *C.* sp. 34 is gonochoric and shares typological key characters with other Elegans supergroup species, but strikingly, adults are nearly twice as long as *C. elegans*. The optimal culture temperature (27°C) for *C.* sp. 34 is significantly higher than that of *C. elegans* (20°C). Dauer larvae were detected in the fig syconia, but generally not observed in laboratory culture conditions. Despite these marked ecological and morphological differences, phylogenetic analysis based on the genome sequences revealed that *C.* sp. 34 is a long-sought sister species to *C. elegans*. We assembled a draft genome sequence of *C.* sp. 34 using data from a mixture of sequencing technologies (Illumina and PacBio). A similar number of protein-coding genes to the *C. elegans* genome was predicted,

but 7TM GPCR domains are diminished in *C.* sp. 34, whereas transposon-related domains are highly enriched. To make *C.* sp. 34 a genetically tractable satellite organism, we have been developing genetic and molecular techniques/tools by transferring the ones established in *C. elegans*. Heritable transgenic lines were obtained by microinjection of commonly used *C. elegans* marker plasmids into female adult gonads, although the frequency was lower than that in *C. elegans*. Both soaking and feeding RNAi in *C.* sp.34 worked as efficiently as in *C. elegans*. Taken together, its high-quality genome information, genetic tractability, and characteristic morphology and ecology make *C.* sp. 34 an attractive satellite model organism for a wide range of studies in comparative and evolutionary biology.

W4129C Large-scale genetic interaction maps for *C. elegans* embryonic development. *P. G. Cipriani*[1,2], E. Munarriz[3], K. Erickson[1], J. Lucas[1,2], N. Smit[1], F. Ahmed[2], J. Reboul[4], K. Gunsalus[1,2], F. Piano[1,2]. 1) New York University, New York, NY; 2) New York University Abu Dhabi, Abu Dhabi, UAE; 3) University of Buenos Aires, Buenos Aires, Argentina; 4) INSERM, France.

Genetic interactions are functional associations between genes that are revealed upon simultaneous perturbation of two genetic loci. Genetic interactions provide information about how pathways buffer each other to maintain an organism's homeostasis and can be used to identify previously unknown components and regulatory relationships within molecular networks. While only around 15% of genes appear to be essential on their own, expression studies tell us that over half of the transcriptome is typically expressed in any individual cell. To learn more about how essential and non-essential genes work together in embryonic development, we devised and implemented a high-throughput (HTP) system for RNAi-based genetic interaction studies. We first completed a pilot study testing a large set of predicted genetic interactions, and we have recently completed genome-wide enhancer and suppressor screens using 24 strains harboring temperature-sensitive alleles of genes that are essential for different aspects of early embryogenesis. The primary screen consisted of over 50 genome-wide RNAi screens in the conditional strains and over 30 additional screens in the N2 control, at multiple temperatures; we rescreened thousands of potential enhancers and suppressors in secondary assays with at least eight replicates. Suppressor interactions that were reproducible in multiple assays have been confirmed using both manual scoring and automated image analysis with our DevStaR algorithm (White et al., 2013). The final suppressor network links over 500 genes through more than 900 interactions; the enhancer network is not yet finalized, but based on results from our pilot study, we expect it to be much larger. We have archived all experimental results to enable quantitative scoring of embryonic lethality, and we have built a database for the millions of images collected with a web interface that allows querying and visualization of all the data collected in the screens. Analysis and follow-up studies of suppressor and enhancer interactions are ongoing.

W4130A Truncation of the RUNX transcription factor RNT-1 disrupts dopaminergic signaling in *Caenorhabditis elegans*. *Sarah Baas Robinson*[1], J. Andrew Hardaway[1], Sarah Sturgeon[1], Tessa Popay[1], Daniel Bermingham[1], Phyllis Freeman[1,2], Randy D. Blakely[1]. 1) Vanderbilt University, Nashville, TN; 2) Fisk University, Nashville, TN.

Dopamine (DA) modulates brain circuitry that supports cognition, reward, motor control, and arousal. Perturbed DA signaling is believed to contribute to addiction, ADHD, schizophrenia, and Parkinson's disease. The presynaptic DA transporter (DAT) is a major determinant of DA signaling and increasing evidence indicates that altered regulation of DAT may contribute to risk for these disorders. We have pursued the nematode *Caenorhabditis elegans* as a model system to elucidate novel mechanisms regulating DAT and/or DA signaling. DA is important for swimming behavior in the worm, as ablation of the *C. elegans* gene encoding DAT (*dat-1*) results in swimming-induced paralysis (Swip). To determine novel presynaptic regulators of DA signaling, we undertook a chemical mutagenesis screen and identified a mutant, *vt34*, that exhibits robust DA-dependent Swip. *vt34* exhibits biochemical and behavioral phenotypes consist with reduced DAT-1 function, with reversal of Swip observed in *vt34* mutants crossed to either *cat-2*, which encodes the DA biosynthetic enzyme tyrosine hydroxylase, or *dop-3*, which encodes a D2 subtype DA receptor. Additionally, *vt34; dat-1* double mutants exhibit an enhanced Swip phenotype. Unlike *dat-1* animals, however, *vt34* has altered male tail morphology and reduced body size, which we found arises from a premature stop codon in the Runx transcription factor ortholog RNT-1. *rnt-1(ok351)* and *rnt-1(tm388)* mutants, as well as mutations in RNT-1's binding partner, *bro-1*, also exhibit Swip. Both bioinformatics and reporter expression studies support the expression of *rnt-1* by DA neurons. Lastly, *vt34* and *rnt-1* mutants exhibit reduced mRNA levels of *dat-1* and *cat-2*, further supporting a role for *rnt-1* in regulating pathways that dictate the capacity for DA signaling. This work was supported by NIH awards T32 MH065215 (SBR), F31 MH093102 (JAH) and MH095044 (RDB).

W4131B Genome-wide mapping in *C. elegans* using a bulk segregant approach. *E. Ben-David*[1], A. Burga[1], L. Kruglyak[1,2,3]. 1) Department of Human Genetics, University of California, Los Angeles, Los Angeles, California 90095, USA; 2) Howard Hughes Medical Institute, University of California, Los Angeles, Los Angeles, California 90095, USA; 3) Department of Biological Chemistry, University of California, Los Angeles, California 90095, USA.

Despite decades of research, the genetic architecture underlying most complex traits – traits with contribution of multiple genetic and environmental factors – remains poorly understood. Many factors, including complex population structure, difficulty in acquiring large sample sizes, genetic heterogeneity and others, have complicated the study of complex traits in humans, and model organisms have provided an excellent tool for studying such traits. In *C. elegans*, quantitative trait loci (QTL) mapping has been used to identify genetic variation between strains that underlie many aspects of the worm's physiology and behavior. So far, QTL mapping in *C. elegans* has been performed using panels of recombinant inbred lines (RILs). Such panels, while providing an excellent tool for mapping differences across strains, are usually limited to comparisons across two backgrounds, and are arduous to generate, limiting the scalability of the approach to multiple strain backgrounds or transgenic animals.

To deal with these limitations, we developed a bulk segregant approach for mapping genetic traits in *C. elegans*. Our approach is based on mutants in which reproduction is obligate sexual, that are allowed to mate for multiple generations. The resultant segregant pool can be subjected to selection, and groups of segregants showing differential phenotypes can be used for mapping. Using simulations, we compared

the power of this approach to other mapping approaches under different assmuptions. We then applied this method to a cross between the lab Bristol (N2) strain and a wild Hawaii isolate (CB4856), and identified QTLs associated with fitness. Finally, in a cross between two transgenic strains under different backgrounds, we identified a distant-acting QTL underlying differences in the expression of a fluorescent marker.

W4132C Rational design of protein coding sequences that evade piRNA-mediated germline silencing. *Daniel J. Dickinson*, Bob Goldstein. Department of Biology and Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC.

In the *C. elegans* germline, multiple mechanisms act to silence foreign DNA. Because these pathways can silence experimentally introduced transgenes, they pose a technical challenge to biologists studying the germline and early embryo. Developing strategies to overcome or bypass silencing of transgenes would facilitate research in multiple fields that use *C. elegans* embryos as a model system. One pathway that can silence single-copy foreign sequences involves recognition of the foreign DNA by genomically encoded 21U-RNAs, which initiate silencing through the Piwi Argonaute PRG-1 (Shirayama et al. 2012). The diversity of 21U-RNAs is high enough to target essentially any DNA sequence. Endogenous germline genes are protected from silencing by a second pathway that involves sequence-dependent licensing by 22G-RNAs bound to the Argonaute CSR-1 (Seth et al. 2013). Newly generated transgenes can adopt either an expressed or a silent state as a result of competition between these two pathways. In some cases, recognition of the GFP portion of a transgene by the PRG-1 pathway can lead to complete silencing. Because silencing is sequence-dependent, we thought it should be possible to design protein coding sequences that evade recognition by PRG-1 and thereby escape silencing. Designing sequences that lack 21U-RNA recognition sites is difficult because the number of 21U-RNAs is very large, and their base pairing specificity (i.e., mismatch tolerance) has not been well characterized. However, we reasoned that bona fide germline-expressed genes should be depleted of high-affinity 21U-RNA binding sites, and might also be enriched for 22G-RNA binding sites that could facilitate expression. Therefore, we developed an algorithm that constructs a coding sequence for any protein of interest by assembling short "words" found in germline-expressed genes. We refer to coding sequences generated in this way as "germline optimized." We constructed synthetic transgenes to test whether germline-optimized sequences are resistant to silencing. We obtained robust germline expression of bacterial proteins that were otherwise efficiently silenced. Moreover, by using a germline-optimized GFP coding sequence, we were able to obtain expression of *gfp::cdk-1*, a model transgene that is particularly prone to silencing. We have produced a web-based tool that allows users to evaluate the degree of germline optimality of existing transgenes and to design germline-optimized coding sequences for any protein of interest.

W4133A High-resolution microfluidic imaging platform for high-throughput drug discovery using *C. elegans* disease model. *S. Mondal*, E. Hegarty, C. Martin, S. K. Gokce, N. Ghorashian, A. Ben-Yakar. University of Texas at Austin, Austin, TX.

High-throughput screening of *C. elegans* for drug discovery and gene function would require technological advancements for high-resolution imaging operating at high speeds. To enable both high-speed and high-resolution imaging of multiple *C. elegans* populations, we developed an automated and large-scale microfluidic imaging platform. The platform includes a large-scale microfluidic chip with 96 wells designed in standard microtiter plate format and densely packed trapping channels for each well. The channels are uniquely designed to immobilize approximately 4,000 animals simultaneously in 3 minutes. The automated imaging platform takes 15 z-stack images of all trapped animals, capturing their whole volume in less than 16 minutes with a resolution of a micron. An automated graphical user interface (GUI) loads all the images, identifies single animal and perform image processing steps for phenotyping. Using this platform, we screened more than 100,000 animals of a polyglutamine aggregation (PolyQ) model using a total number of 25 chips. We tested the efficacy of ~1,000 FDA approved drugs in improving the aggregation phenotype in the PolyQ model to identify possible proteostasis modulators with a Z'-factor of 0.80. The study resulted in four potential hits using the protein aggregation model. The platform provides a leap forward for high-throughput screening of other *C. elegans* disease models with cellular or sub-cellular phenotypes.

W4134B Pilot study to map the *Caenorhabditis elegans* metabolome to its genome. *T. Carter*[1], A. Edison[1], F. Ponce[1], G. Gouveia[1], F. Tayyarri[1], E. Andersen[2]. 1) University Of Georgia, Athens, GA; 2) Northwestern University, Evanston, IL.

A complete systems biology analysis requires the integration of different levels of omic information. *C. elegans* is an ideal model organism to develop systems biology methods because of the ease of culturing, the ability for genetic manipulation, and the wealth of existing information generated over decades of study. There are several approaches that one could take to relate the metabolome to the genome, including the use of existing mutants in metabolic pathways, targeting pathways of interest using CRISPR/Cas9 or RNAi, or the use of recombinant inbred lines (RILs). In this methods development study, we used 12 RILs generated by the Andersen lab from parental N2 and Hawaiian (CB4856) strains. These have been sequenced and analyzed by several different methods in the Andersen lab. For our study design, we grew 6 independent biological replicates from each of the 12 RIL strains collected at two time points for a total of 144 samples. These were started from synchronous populations and extracted at two separate time points (6 replicates each) in an effort to distinguish metabolite differences at different developmental stages of the organism. The final populations are "semi-synchronous" and represent distributions of developmental stages, which are then characterized by a COPAS Biosorter. The extracted samples are analyzed using a combination of NMR and LC-MS to obtain metabolomic and glycomic information, which will be deconvoluted into developmental stages. The spectral data are processed and statistically analyzed using a MATLAB metabolomics toolbox used by the Edison Lab. We will report the initial analysis, identification, and quantification of metabolites as a function of genotype and development. This pilot study is the first step in the generation and refinement of mapping the differences in metabolic pathways of *C. elegans* to differences in the genetic make-up of the organism, which will require greater numbers of genetic lines.

W4135C Development of systems biology in *Caenorhabditis elegans*. *A. Edison*, F. Ponce, G. Gouveia, M. Colonna, F. Tayyari, A. Le Guennec, R. Taujale, O. Bifarin, A. Martin, J. Helmken. Deptartments of Genetics and Biochemistry, Institute of Bioinformatics and Complex Carbohydrate Research Center, The University of Georgia, Athens, GA.

Systems biology is the integration of multiple levels of omics data with environmental factors and phenotypic responses. *C. elegans* is an ideal organism for these studies. There are several obstacles to a complete systems biology analysis, especially at the level of metabolomic analysis. Metabolites span a range of chemical classes including amino acids, sugars, lipids, organic acids and are expressed in a very wide range of concentrations ranging from <fM to >mM. There are no existing methods to cover this broad metabolite diversity. Mass spectrometry is extremely sensitive but is not able to reliably identify unknown metabolites that are not well characterized in databases. NMR is capable of unknown metabolite identification but suffers from low sensitivity. We are developing several approaches to help address these problems: "Deep annotation" is a chemical approach to combine the strengths of NMR and MS to relate molecular formulas to compound identifications using large pooled cultures of worms and preparative chemical fractionation techniques. "Developmental distribution" is an approach to extract developmental stage-specific analytical data from several replicates of mixed population cultures that are characterized by a worm sorter. We are applying these approaches to targeted mutations in glycosyltransferases as well as other systems such as recombinant inbred and mutation accumulation lines. I will provide an overview of how these approaches fit together to relate metabolites to genes and phenotypes.

W4136A Metabolomics of developmental stages of *Caenorhabditis elegans* using mixed populations. *Francesca V. Ponce*[1], Fariba Tayyari[1], Goncalo Gouveia[1], Andrew Martin[1], Cord Helmken[1], Chaevien Clendinen[2], Facundo M. Fernández[2], Osman Sheikh[1], Lance Wells[1], Arthur S. Edison[1]. 1) Complex Carbohydrate Research Center, University of Georgia, Athens; 2) School of Chemistry and Biochemistry & Petit Institute for Bioengineering & Bioscience, Georgia Institute of Technology.

Metabolomics analyses attempt to study the complete set of metabolites produced by an organism during its life cycle under all possible conditions. The nematode *C. elegans* is an ideal organism for comparative metabolomics studies. However, detailed analysis of the metabolic traits associated with different life stages of the worm is lacking in part due to low throughput methods to generate and study synchronous worm populations and also due to low sensitivity of some analytical techniques (e.g. NMR), which rely on large amounts of sample for adequate detection. We are developing approaches to combine the use of the large particle flow cytometer COPAS Biosorter, NMR and mass spectrometry to attempt to identify some metabolic traits associated with the different developmental stages of *C. elegans* by sampling and comparing several mixed-stage cultures. The Biosorter can measure the extinction (EXT) and time-of-flight (TOF) of individual nematodes in a population and total population size, which can then be used as descriptors of developmental stages within a mixed population of animals. Samples of synchronous worm populations of 200 thousand individuals were collected at five different time points during a 96-hour period to capture the different developmental stages (L1, L3, L4, Adult, Adult and their progeny) for NMR and MS analyses. A subset of each population was analyzed with the COPAS Biosorter. The frequency distributions of EXT and TOF of each subset were used as a proxy for the developmental stages present in the mixed stage population collected at the last time point. We were able to distinguish distinct features present in different collection time points laying out a platform for the identification of metabolic traits associated with different developmental stages present in a mixed stage culture. This approach allows for standardization and introduction of phenotypical and developmental variables to metabolomics studies. This will aid in the effective characterization of metabolic traits involved in each developmental stage of the *C. elegans* life cycle.

W4137B The EAT-2 and GAR-3 acetylcholine receptors have distinct effects on pharyngeal muscle peristalsis. *A. Kozlova*, M. Lotfi, P. Okkema. University of Illinois at Chicago, Chicago, IL.

Pharyngeal muscles exhibit two distinct types of contractions called pumps and peristalses. A peristalsis is a wave-like contraction followed by rapid relaxation that travels posteriorly through the isthmus, so that only a small portion of the isthmus lumen is open at any time. This contraction is remarkable, because it occurs within individual pm5 muscle cells that extend the entire length of the pharyngeal isthmus. Peristalses occur only after several pumps, and they are dependent on signals from the M4 motor neuron. We are examining how M4 and the isthmus muscles interact to produce these peristalses. M4 is a cholinergic neuron, and we have found that *cha-1* mutants lacking acetylcholine (ACh) fail to pump or peristalse. Chemical stimulation of either muscarinic or nicotinic ACh receptors (mAChRs and nAChRs) in *cha-1* mutants is sufficient to activate peristalsis. We have examined several mutants affecting AChR genes expressed in the pharyngeal muscles and have found that mutants defective in the nAChR *eat-2* and the mAChR *gar-3* exhibit distinct peristaltic defects. *eat-2* mutants pump less frequently than wild-type animals, but most of the pumps are followed by peristalses. The *eat-2* peristalses are prolonged suggesting that EAT-2 stimulates isthmus muscle relaxation. In comparison, *gar-3* mutants fail to respond to the mAChR agonist arecoline indicating GAR-3 mediates peristalsis in response to exogenous arecoline. *gar-3* mutation also suppresses the prolonged peristalses observed in *eat-2* mutants, which suggests that these prolonged contractions are stimulated by GAR-3. To understand better how these AChRs affect peristalsis, we examined Ca^{2+} dynamics in the isthmus muscles using GCaMP3. Wild-type animals display a broad increase in Ca^{2+} in the center of the isthmus during pumps followed by wave-like Ca^{2+} transients in the posterior isthmus during peristalses. We found that changes in Ca^{2+} concentration during peristalsis in *gar-3* mutants are similar to those in wild type, and this is consistent with our observation that *gar-3* mutants do not have any defects in peristalsis under normal conditions. In contrast, *eat-2* mutants have larger changes in Ca^{2+} concentration in the posterior isthmus during peristalsis, and these Ca^{2+} transients are prolonged in *eat-2* mutants when compared to those in wild-type animals. Based on our observations, we conclude that GAR-3 is the receptor which mediates peristalsis in response to exogenous arecoline, but not essential for these contractions under normal conditions. Surprisingly, we found that EAT-2 may be involved in stimulation of isthmus muscle relaxation, rather than isthmus muscle contraction.

W4138C Identification of genetic variation in *Caenorhabditis elegans* bleomycin sensitivity. *S. C. Brady*, S. Rosenberg, S. Zdraljevic, E. C. Andersen. Northwestern University, Evanston, IL.

Individuals within a population vary across a broad range of traits, including many that are influenced by multiple genetic factors as well as the environment. Complex traits that are medically relevant include susceptibilities to many common diseases, such as cancer, along with sensitivity to drugs, such as chemotherapeutics. However, the identification and validation of genetic loci underlying complex traits in humans is difficult. *Caenorhabditis elegans* is a tractable model that can be used to identify the genetic factors that cause variation in complex traits by pairing high-throughput phenotypic assays with a broad range of genetic tools.

Like humans, strains of *C. elegans,* vary in sensitivity to the chemotherapeutic drug bleomycin. The laboratory strain, N2, is sensitive to the drug whereas a genetically diverged strain, CB4856, is more resistant. We examined bleomycin sensitivity in a panel of 350 whole-genome sequenced recombinant inbred advanced intercross lines (RIAILs) generated from a cross between the N2 and CB4856 parents. Recombinant strains exhibited variation in bleomycin sensitivity as determined by changes in growth rate, offspring production, and feeding rate. Approximately 1,600 markers across the genome were used to correlate genotype with phenotype. Linkage analysis identified a quantitative trait locus (QTL) on chromosome V with a 162-kb confidence interval that is strongly correlated with bleomycin sensitivity. Within this interval, we identified five candidate genes — three genes with nonsynonymous variants and two genes with varied gene expression between N2 and CB4856.

I have developed a multi-pronged approach to identify any and all causative variants that contribute to bleomycin sensitivity. This approach involves experimental and computational methods, including building nearly isogenic lines (NILs) to empirically narrow the interval and determine the effect of the chromosome V QTL on bleomycin sensitivity as well as creating CRISPR-generated knock-out alleles of each candidate gene in both genetic backgrounds. Ultimately, I aim to identify the gene(s) within the 162-kb QTL on chromosome V in which variation explains differential sensitivity to bleomycin, thus improving our understanding of variation in human response to this chemotherapeutic.

W4139A Genetic and molecular tools for *Caenorhabditis* sp. 34, a sister species of *C. elegans* with a larger body size. *K. Tsuyama*[1], S. Namai[1], R. Kumagai[1], T. Shimura[1], N. Kanzaki[2], T. Kikuchi[3], A. Sugimoto[1]. 1) Tohoku University, Sendai, Miyagi, JP; 2) Forestry and Forest Products Research Institute, Tsukuba, Japan; 3) University of Miyazaki, Miyazaki, Japan.

Caenorhabditis sp. 34 is a sister species of *C. elegans* recently isolated from syconia of the fig *Ficus septica* on Ishigaki Island, Japan. Although their genome sequences are the closest each other, there are striking developmental and morphological differences between *C.* sp. 34 and *C. elegans*. For example, *C.* sp. 34 adults are two times longer than *C. elegans*; *C.* sp. 34 has female and male, unlike *C. elegans* that has hermaphrodite and male. The genome similarity and phenotype differences make this organism highly attractive as a satellite model for *C. elegans* in comparative and evolutionary biological studies.

To make *C.* sp. 34 more tractable, we are developing genetic and molecular tools for *C.* sp. 34, by emulating the rich experimental techniques established in *C. elegans.* **1) Immunofluorescence.** A panel of antibodies against *C. elegans* proteins was used for immunofluorescence of *C.* sp. 34 embryos, many of which successfully recognized expected structures in *C.* sp. 34. Notably, polyclonal antibodies against *C. elegans* PGL-1/3 recognized P granule-like granules in *C.* sp. 34 embryos, but their size was smaller and more dispersed than their *C. elegans* counterparts, implying the distinct dynamics of germ granules between these two species. **2) Transgenesis.** We examined transgenesis in *C.* sp. 34 by microinjecting transgenic marker plasmids commonly used in *C. elegans*. Although the frequency was lower than that in *C. elegans*, stable transgenic lines were obtained for all transgenes tested, and their expected phenotypes (Rol for *rol-6(su1006)*) or expression patterns (Psur-5::GFP (universal), Punc-122::GFP/RFP (coelomocytes), Pmyo-3::mCherry (body wall muscle), Podr-1::GFP (AWC neuron)) were detected. Thus, promoters and 3'-UTR sequences of *C. elegans* appear generally functional in *C.* sp. 34. **3) RNAi.** We tested RNAi in *C.* sp. 34 using the soaking and feeding methods. The soaking RNAi of the *tbg-1* (g-tubulin) ortholog of *C.* sp. 34 resulted in early embryonic lethality at a high penetrance, with phenotypes similar to those of *tbg-1(RNAi)* in *C. elegans*. Feeding RNAi for the GFP coding sequence in the GFP-transgenic *C.* sp. 34 animals efficiently reduced the GFP signal. Thus, *C.* sp. 34 is highly sensitive to RNAi via ingested dsRNAs.

Taken together, many of the genetic techniques, molecular tools and resources of *C. elegans* can be directly transferred to *C.* sp. 34. The relative feasibility of importing *C. elegans* techniques and resources will allow rapid establishment of *C.* sp. 34 as a satellite model species for evolutionary studies. Now we plan to use these techniques and tools for dissecting the genetic bases for morphological and developmental differences between *C.* sp. 34 and *C. elegans*.

W4140B Neurologic and Genetic Analysis of *Ginkgo biloba* Extract Effects in *Caenorhabditis elegans*. *H. Cathcart*, A. Battle, M. Thomas, C. Thurber. Abraham Baldwin Agricultural College, Tifton, GA.

Ginkgo biloba extract (GBE), which is rich in antioxidants is often used as an alternative treatment to postpone the development of Alzheimer's disease (AD) symptoms, but little is known regarding its protective mechanisms. The nematode, *Caenorhabditis elegans*, is a valuable tool for studying AD because it expresses an APP ortholog, apl-1, which has been implicated in the insulin signaling pathway and in larval development. Our study was two-fold. 1) We examined the touch withdrawal response of *C. elegans* strains overexpressing apl-1 that were GBE treated and untreated. An eyelash was used to gently tap on the posterior and anterior ends of the nematodes to determine habituation and memory. 2) RNA sequencing was used to determine the expression level of genes affected by GBE in both wild type (N2) and mutant strains. Total RNA was extracted using the Purelink© RNA Mini Kit, while libraries and sequencing were performed at the New York Genome Center. By combining these phenotypic and genotypic methods, we expect to identify genes and mutations responsible for molting and memory defects in this important model species.

W4141C Evaluation of single-cell RNA sequencing measurements for use in developmental lineage reconstruction. *H. Dueck*, E. Torre, S. Shaffer, A. Raj, J. Murray. University of Pennsylvania, Philadelphia, PA.

The process of development in multicellular organisms may be specified by a lineage tree, whose structure represents the developmental trajectory of each cell, and by the dynamic gene expression changes that occur in individual cells progressing along these trajectories. Transcriptome measurements from single developing cells may provide sufficient information to infer an unknown lineage and estimate lineage-specific expression dynamics. Single-cell RNA sequencing provides a method to make such measurements; however, the adequacy of scRNA-seq measurements for developmental lineage reconstruction is unknown. In particular, technical noise may generate spurious expression similarity between cells and limited sensitivity may prevent detection of critical regulators that are expressed at low levels.

Here, we evaluate the adequacy of Drop-seq [1] for developmental lineage reconstruction. This recently developed scRNA-seq method provides high-throughput measurements at low cost and so could be used to measure the transcriptomes of individual cells densely sampled over developmental time, even for large lineage trees. We generated expression measurements for thousands of melanoma cells using both Drop-seq and single-molecule florescence *in situ* hybridization (smFISH) for hundreds of genes. We compare the population distribution of expression levels estimated using these methods and, treating smFISH as a gold standard, provide a gene-level assessment of Drop-seq measurements in terms of sensitivity, precision and accuracy. We consider the relative strengths of *in situ* imaging and sequencing methods, as well as the possibility of integration of these different data types. As proof of concept, we are generating Drop-seq measurements for individual C. elegans cells from dissociated mixed-stage embryos. We will compare these data to dynamic, single cell expression measurements of the developing worm generated by automated lineage-tracing microscopy. Through this comparison, we will further assess potential sampling bias in the Drop-seq method and the ability to detect key developmental genes.

1. Macosko, Evan Z., Anindita Basu, Rahul Satija, James Nemesh, Karthik Shekhar, Melissa Goldman, Itay Tirosh, et al. *Cell* 161, no. 5 (May 21, 2015): 1202–14.

W4142A Chromsosomal context influences X chromosome targeting by the C. elegans Dosage Compensation Complex. *S. E. Albritton*, L. W. Winterkorn, A. L. Kranz, S. Ercan. New York University, New York, NY.

Multi-subunit condensin complexes are essential for chromosome condensation during both mitosis and meiosis and have also been implicated as having important roles in transcriptional regulation during interphase. Metazoans contain two condensin complexes, I and II, which specifically localize to different chromosome regions where they perform different functions. Caenorhabditis elegans contains a third condensin complex, Condensin DC, whose localization is uniquely restricted to the hermaphrodite X chromosome where it acts as part of the Dosage Compensation Complex (DCC) to repress X-transcription. The regulatory mechanisms by which Condensin DC is targeted specifically to the X chromosome are not yet fully understood.

As part of the DCC, Condensin DC interacts with at least four other non-condensin proteins, including two zinc-finger-containing proteins, SDC-2 and SDC-3, which act to recruit Condensin DC to approximately 100 recruitment sites across the X-chromosome. Evidence suggests that this initial targeting is sequence-dependent. Sites of initial recruitment, termed recruitment elements on X (rex), are enriched for a 10bp recruitment motif. Our analyses indicate that this motif is four times enriched on the X-chromosome as compared to autosomes and is often clustered at rex-sites. However, the motif is not unique to the X-chromosome; both the X chromosome and the autosomes contain many perfect matches that are not bound by the DCC. Further, we show that insertion of a rex-site in single-copy onto an autosome fails to detectably recruit DCC. Increasing the number of inserted rex-site copies overcomes the inability recruit on autosomes. We conclude that motif sequence, while important for DCC recruitment, is not sufficient to recruit the complex on its own. We hypothesize that chromosomal context of the X chromosome facilitates the specificity of DCC recruitment.

W4143B Identification of *lin-35* (Rb) suppressors. *Cynthia Becker*, Lo Te-Wen. Ithaca College, Ithaca, NY.

Proper development of an organism requires the precise regulation of many genetic factors. Mis-regulation of gene expression often results in human diseases such as cancer. This can be caused by mutations in key classes of genes required for cellular development. Tumor suppressor genes are one class of genes known to play a role in cancer prevention. In mammals, retinoblastoma (Rb) is a tumor suppressor gene that, when inactivated, promotes cancer. We are using *C. elegans* as a model to study Rb function. We performed an RNAi screen to identify suppressors of *lin-35*, the *C. elegans* Rb homolog.

Our study builds directly on an RNAi suppressor screen previously published by Polley and Fay (2012). Polley and Fay exploited the genetic interaction between *lin-35* and *slr-2*. *lin-35* and *slr-2* act redundantly in the intestine and as a result, simultaneous mutations in both genes result in a synthetic lethal phenotype. In order to circumvent the synthetic lethality and to maintain the strain, Polley and Fay expressed a wild-type copy of *lin-35* in the double mutant as an extrachromosomal array with a GFP marker. Worms that contain the array, and therefore a wild-type copy of *lin-35*, can live past the larval stage. This array is lost in about 30% of offspring resulting in non-green offspring that would die as young L1 larvae, unless the lethality is suppressed by RNAi knockdown of another gene.

This screen is exceptionally well-suited for teaching genetics concepts and techniques. As a teaching tool, the preliminary screen was performed in a genetics lab course at Ithaca College. In Spring 2015, the genetics class screened the supplemental X chromosome Ahringer RNAi library. They identified 171 out of 371 genes as potential suppressors. In the Lo lab, through additional experiments, we have identified 50 of the strongest suppressors of the *lin-35* lethal phenotype. For each experiment, we included known suppressors of *lin-35* as positive controls to ensure all reagents and techniques functioned properly. RNAi bacteria that did not target a gene was included in each experiment as a negative control.

Ongoing research including additional viability and larval arrest experiments will further identify the most relevant suppressors. Ultimately, these studies will help identify components of the Rb tumor suppressor pathway and better inform future human disease treatments.

W4144C Mutagenesis of GATA motifs controlling the endoderm regulator *elt-2* reveals distinct dominant and secondary *cis*-regulatory elements. *Lawrence Du*, Sharon Tracy, Scott Rifkin. University of California San Diego, La Jolla, CA.

Cis-regulatory elements (CREs) are crucial links in developmental gene regulatory networks, but in many cases, it can be difficult to discern whether similar CREs are functionally equivalent. We found that despite similar conservation and binding capability to upstream activators, different GATA *cis*-regulatory motifs within the promoter of the *C. elegans* endoderm regulator *elt-2* play distinctive roles in activating and modulating gene expression throughout development. We fused wild-type and mutant versions of the *elt-2* promoter to a *gfp* reporter and inserted these constructs as single copies into the *C. elegans* genome. We then counted early embryonic *gfp* transcripts using single-molecule RNA FISH (smFISH) and quantified gut GFP fluorescence. We determined that a single primary dominant GATA motif located -527 bp upstream of the *elt-2* start codon was necessary for both embryonic activation and later maintenance of transcription, while nearby secondary GATA motifs played largely subtle roles in modulating postembryonic levels of *elt-2*. Mutation of the primary activating site increased low-level spatiotemporally ectopic stochastic transcription, indicating that this site acts repressively in non-endoderm cells. Our results reveal that CREs with similar GATA factor binding affinities in close proximity can play very divergent context-dependent roles in regulating the expression of a developmentally critical gene *in vivo*.

W4145A Direct and positive regulation of *bed-3* by BLMP-1 in *C. elegans*. *H. T. Fong*, J. Yang, W. H. Tan, T. Inoue. National University of Singapore, Singapore, SG.

C. elegans BLMP-1, the ortholog of the mammalian zinc finger transcriptional repressor PRDM1/BLIMP1, plays an important role in the heterochronic pathway regulating developmental timing. Previously, we have reported that BLMP-1 positively regulates *bed-3*, a gene required for molting and vulval development. By performing *in vivo* reporter assays and quantitative PCR, we have shown that *bed-3* transcription is downregulated upon BLMP-1 knocked down. Using electrophorectic mobility shift assay (EMSA), we identified two BLMP-1 binding motifs in the 200bp SF2-9 enhancer region located within *bed-3* intron 3. In addition, through RNAi screening and double knock-downed assays, we identified candidate chromatin factors and co-activators which may act with BLMP-1 to regulate *bed-3* transcription. We anticipate that analysis of these components will reveal the mechanism by which BLMP-1 functions as a positive regulator of *bed-3*, and give us better understanding of how the heterochronic pathways regulates molting and vulval development.

W4146B Cellular proteomes drive tissue-specific regulation of the heat shock response. *E. Guisbert*, C. Grant, J. Ma, K. Kim Guisbert. Florida Institute of Technology, Melbourne, FL.

The heat shock response (HSR) senses protein misfolding in the cell and induces a set of conserved heat shock proteins, many of which help to restore protein homeostasis (proteostasis). The HSR is a cell-autonomous response, but under some conditions, it can be coordinately regulated across tissues and throughout the whole organism. Currently, the distinctions between cell-autonomous and coordinate HSR regulation are not well established.

Previously, we identified a tissue-specific HSR regulatory network in *Caenorhabditis elegans*. Here, we analyze several of these regulators and uncover mechanisms that drive their tissue-specific HSR regulation. We find that muscle-specific regulation of the HSR by the TRiC/CCT chaperonin complex is not driven by muscle-specific expression of the TRiC/CCT complex itself, but rather by actin, one of its the primary cellular substrates. Actin knockdown reduces the sensitivity of muscle to TRiC/CCT and broad overexpression of an actin isoform expands the tissue-specificity of TRiC/CCT regulation of the HSR by sensitizing intestinal cells. Additionally, we characterized the actin overexpression line and found that it has several interesting phenotypes, including shortened lifespan, supporting other recent research suggesting that maintenance of the actin cytoskeleton is an important factor for maintaining longevity. Futhermore, we show that intestine-specific regulation of the HSR by components of the secretory pathway is driven by the vitellogenins, some of the major secreted proteins in the intestine.

Together, these data reveal that tissue-specific regulation of the HSR reflects a balance between the protein homeostasis (proteostasis) machinery and the specific requirements arising from the cellular proteome. This tissue-specific regulatory mechanism is similar to the well-established regulation of the HSR by the HSP70 and HSP90 chaperones that is also dependent on their cellular substrates but is not tissue-specific. Our findings that distinct cellular proteomes influence HSR regulation have important implications because the HSR has been implicated in a variety of tissue-specific diseases including cancers and neurodegenerative diseases.

W4147C A sexually dimorphic transcriptional switch integrates information about microbial environment and nutritional state to regulate exploratory behavior of *C. elegans*. *Z. A. Hilbert*, D. H. Kim. MIT, Cambridge, MA.

In their natural environments, *C. elegans* integrate a wide array of information to make behavioral decisions. We have previously reported that exposure to the pathogenic bacteria *Pseudomonas aeruginosa* can alter the neuronal expression pattern of the DAF-7/TGFß ligand, inducing expression in the ASJ neuron pair of hermaphrodite animals (Meisel, J.D. *et al. Cell* (2014)). Here, we show that males exhibit the induction of *daf-7* expression in the ASJ neuron pair even in the absence of *P. aeruginosa*. This sexually dimorphic transcriptional switch is turned on in an age-specific manner in adult males and is required for the male-specific mate searching behavior. Moreover, we have found that expression of *daf-7* in the male ASJ neurons is dynamically regulated by the availability of bacterial food. We observe that starved male animals repress the activation of *daf-7* expression in ASJ that promotes mate-searching behavior. In contrast, when these starved animals are challenged with a pathogenic food source, they rapidly up-regulate *daf-7* expression in the ASJ neuron pair indicating that a worm will prioritize pathogen avoidance over seeking food when starved, which in turn is prioritized over mate searching. Our data suggest that sex, development, nutritional state and microbial environment are all integrated in the hierarchical regulation of a transcriptional switch in the ASJ neuron pair to regulate exploratory behavior.

W4148A Dynamic trans-splicing in *C. elegans*. *Marija Jovanovic*, Jiarui Li, Justin White, Jack Chen. Simon Fraser University, Burnaby, Canada.

Trans-splicing occurs when two distinct RNA molecules, which originate from different genomic regions, are spliced together. This phenomenon occurs in a wide range of organisms, including nematodes and mammals. In *C. elegans*, a particular form of trans-splicing takes place. During the post-transcriptional processing of pre-mRNA, a highly conserved splice leader sequence is spliced to the 5' end of transcripts. Earlier efforts that quantified trans-splicing in *C. elegans* suggest that 70% of genes are trans-spliced. The goal of this research is to examine whether trans-splicing in *C. elegans* is static or dynamic in developmental stages in different tissue types and to ascertain the functional impact of trans-splicing in *C. elegans*. In this project, we examined trans-splicing events for all genes and study the dynamics of trans-splicing in different conditions, using Iso-seq data we have generated and taking advantage of existing RNA-seq data generated by the modENCODE projects.

Our research used a combination of computational analysis and bioinformatics software to characterize trans-splicing events. We used Iso-seq data to study the nature of trans-splicing events in the context of full-length transcripts, the results of which were used to determine parameters for predicting and annotating trans-splicing acceptor sites. We predicted candidate trans-splicing acceptor sites based on the genome sequences and location of trans-splicing sites. Using RNA-seq data and the genome-sequence-based prediction of trans-splicing acceptor sites, we annotated trans-splicing events under various conditions, including developmental stages and tissue types. These results enabled us to compare the trans-splicing status across stages and conditions so that we can elucidate the dynamics of trans-splicing activities. Our analysis revealed that trans-splicing in *C. elegans* is a dynamic and regulated process, which may play a role in maintaining the level of translated genes. In this presentation, we will elaborate a genome-wide analysis of trans-splicing in *C. elegans*, with a focus on the dynamics of trans-splicing, tissue- and developmental-stage specific trans-splicing, and constitutive trans-splicing, aiming to elucidate the functional impact of trans-splicing in *C. elegans*.

W4149B Hox proteins generate neuronal diversity by regulating the transcriptional output of a single terminal selector gene. *P. Kratsios*[1,2], S. Y. Kerk[2], O. Hobert[2]. 1) University of Chicago, Chicago, IL; 2) HHMI, Columbia University, New York, NY.

Understanding how the expression of neuron class-specific genes is established during development is of key importance to the problem of neuronal diversity. Exploiting the molecular diversity of distinct motor neuron (MN) classes in *C.elegans*, we show that the evolutionarily conserved COE (Collier, Olf, Ebf) - type terminal selector UNC-3 is required for MN diversity by directly regulating the expression of MN class-specific terminal identity genes, such as ion channels and neurotransmitter receptors. We further find that Hox proteins cooperate with UNC-3 and remarkably employ two distinct, region-based strategies to generate MN diversity. In the *C.elegans* ventral nerve cord (VNC), the more anteriorly expressed *Hox* genes, *lin-39*/Scr/Dfd and *mab-5* (Antennapedia-type), as well as the Hox cofactor *ceh-20*/Exd/Pbx are required for expression of MN class-specific terminal identity genes. Our mutational analysis shows that *lin-39* and *mab-5* – similarly to UNC-3 – directly activate MN class-specific genes, revealing a coactivation strategy that generates MN diversity along the VNC. Conversely, the posterior *Hox* gene *egl-5/Abd-B* acts as a repressor of *lin-39* and *mab-5 expression*, thereby diversifying posteriorly located MN subclasses from their anterior homologs. Genetic removal of *egl-5* results in homeotic transformation of posterior MN subclasses as evidenced by molecular and anatomical criteria. Intriguingly, we find that *unc-3* and *Hox* orthologs are coexpressed in mouse MNs along the spinal cord, suggesting that this intersectional, region-based gene regulatory principle we uncovered in *C.elegans* may be conserved across phylogeny to generate neuronal diversity.

W4150C X-box promoter motif searches: from *C. elegans* to humans to novel candidate ciliopathies. *G. Lauter*[1], K. Tammimies[1,2], A. Bieder[1], D. Sugiaman-Trapman[1], R. Torchet[1], M.-E. Hokkanen[3], J. Burghoorn[1], E. Castrén[3], J. Kere[1,4], I. Tapia-Páez[1], P. Swoboda[1]. 1) Department of Biosciences and Nutrition, Karolinska Institutet, Huddinge, Sweden; 2) Centre of Neurodevelopmental Disorders (KIND), Pediatric Neuropsychiatry Unit, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden; 3) Neuroscience Center, University of Helsinki, Helsinki, Finland; 4) Molecular Neurology Research Program, University of Helsinki, Helsinki, Finland and Folkhälsan Institute of Genetics, Helsinki, Finland.

Cilia are highly conserved organelles protruding from dendrites of certain sensory neurons in *C. elegans* and from the cell surfaces of various cell types in other species. Since cilia are implicated in essential cellular processes, defects of ciliary structure and function have been identified as the underlying causes of severe genetic disorders collectively called ciliopathies. We make use of the X-box promoter motif recognized by the RFX transcription factor DAF-19, the major regulator of ciliogenesis in *C. elegans*, to identify genes involved in human ciliopathies. Using a C. *elegans* derived X-box search, we have identified several hundred human genes with conserved X-box motifs. The identified X-box genes are candidate ciliary genes as is the case in *C. elegans*, *Drosophila melanogaster* and other species. Currently, we focus on genes associated with dyslexia, the most common reading disorder. In the promoter regions of human *DYX1C1*, *DCDC2* and *KIAA0319*, three of the most replicated dyslexia candidate genes, we identified conserved X-box motifs. We demonstrate their functionality as well as ability to recruit RFX TFs using reporter gene and electrophoretic mobility shift assays. Furthermore, we uncover a complex regulatory interplay between human RFX1, RFX2, RFX3 and their effect on the endogenous expression of *DYX1C1* and *DCDC2* in human retinal pigment epithelial (RPE-1) cells. Induction of ciliogenesis increases the expression of RFX TFs and dyslexia candidate genes. Endogenous DYX1C1 localizes to the base of the cilium while DCDC2 localizes along the entire ciliary axoneme. Finally, over-expression of human DCDC2 leads to ectopic branching of ciliated neurons in *C. elegans*. Our results demonstrate that the evolutionarily conserved X-box promoter motif can be used to identify ciliary candidate genes across species.

W4151A *Caenorhabditis elegans* BMP Transcriptional Program Implicates Collagen Remodeling in Body Size Regulation. *U. Madaan*[1], M. Meade[1], E. Yzeiraj[1], C. Rushlow[2], C. Savage-Dunn[1]. 1) Queens College, Flushing, NY; 2) New York University, NY.

Cell-cell communication is required for proper development and survival of an organism. One form of cell-cell communication uses signal transduction pathways such as the TGF-β pathway. TGF-β pathways are critical for developmental processes such as cell growth, cell division and organ development. TGF-β ligands signal through a type I and type II receptor and intracellular signal transducers called Smads. Binding of the ligand to its receptors allows for phosphorylation of Smads which then complex together and are shuttled to the nucleus and regulate target genes of the TGF-β pathway. The TGF-β ligands are conserved across animal phyla and a homolog of TGF-β in the nematode *C. elegans* is DBL-1. We previously established DBL-1 signaling in the epidermis of the worm as necessary and sufficient for normal body size. However, it is not clear which genes are directly responsible for changes in body size and what is the mechanism leading to a small worm. **We present evidence implicating cuticle collagen genes as the effector genes responsible for the small body size phenotype resulting from defects in DBL-1 signaling.** First, we show through EMSA and analysis of ChIP-seq data that specific collagen genes are direct or indirect targets of Smad regulation. Next, we establish through RNAi inhibition and overexpression that DBL-1-regulated cuticle collagen genes are positive and negative regulators of body size. Future work aims to determine whether changes in the exoskeleton structure of the worm affects DBL-1 signaling.

W4152B Activation and Repression of Target Gene Expression in Neurons by the *C. elegans* RFX Transcription Factor, DAF-19. *K. Mueller*[1], Z. Ek-Vasquez[1], S. Scholtz[1], H. Olson[1], P. Phirke[2], D. Sugiaman-Trapman[2], P. Swoboda[2], E. A. De Stasio[1]. 1) Lawrence University, Appleton, WI; 2) Karolinska Institute, Stockholm-Huddinge, Sweden.

DAF-19, the only RFX transcription factor found in *C. elegans*, is required for the formation of neuronal sensory cilia. Four isoforms of the DAF-19 protein have been reported, and the *m86* nonsense (null) mutation affecting all four isoforms has been shown to prevent cilia formation. Transcriptome analyses employing microarrays of L1 and adult stage worms were completed using RNA from *daf-19(m86)* worms and an isogenic wild type strain to identify additional putative DAF-19 target genes. Using transcriptional fusions with GFP, we compared the expression patterns of several potential gene targets using fluorescence confocal microscopy. Expression patterns were characterized in various genetic backgrounds in order to determine isoform-specific expression patterns. Additionally, we completed rescue experiments using cDNAs encoding specific DAF-19 isoforms in a *daf-19* null genetic background. Our data indicate that at least five new genes are activated and four new genes are repressed by DAF-19 in both ciliated and non-ciliated neurons. Few of these genes are known to contain a classical X-box motif through which DAF-19 gene regulation is thought to occur. We are currently developing isoform-specific CRISPR/Cas9 mutants to further explore the precise mechanisms by which different DAF-19 isoforms regulate their target genes.

W4153C Regulation of anterior lineage genes in *C. elegans* embryogenesis. *J. D. Rumley*, A. Zacharias, J. I. Murray. University of Pennsylvania, Philadelphia, PA.

Embryonic patterning requires many signaling pathways to control cell fates. A fundamental step in development is patterning the body axes. Antero-posterior axis patterning depends on the Wnt pathway, which acts through the transcription factor TCF and its coactivator β-catenin. Classic Wnt targets are transcriptionally activated when Wnt signaling is active through the TCF:β-catenin complex binding to *cis* regulatory regions and are repressed when Wnt signaling is inactive through TCF binding without β-catenin. In contrast, emerging evidence suggests the existence of direct "opposite" targets, activated by TCF without β-catenin and repressed by TCF:β-catenin.

In the *C. elegans* embryo, almost all cell divisions are patterned by a Wnt pathway variant, called the Wnt/β-catenin asymmetry pathway, in which nuclear level of POP-1/TCF is higher in the unsignaled anterior sister cell and nuclear level of SYS-1/β-catenin is higher in the signaled posterior sister cell. Many genes expressed during embryogenesis are differentially expressed between anterior and posterior sister lineages. Several genes expressed in posterior lineages are classic Wnt targets, expressed when Wnt signaling is active. On the contrary, the regulation of anterior lineage genes is not well understood. I am testing whether these genes are direct opposite Wnt targets and how they are regulated. RNAi depletion of either POP-1 or SYS-1 shows that these factors are necessary for proper regulation of anterior genes but does not distinguish direct from indirect regulation. I will identify anterior gene enhancers, and determine if these enhancers are bound by POP-1 and if any POP-1-bound sites are necessary for anteriorly biased expression.

This work will clarify mechanisms regulating expression of anterior sister lineage genes in the *C. elegans* embryo, and may have implications for Wnt pathway regulation of genes expressed in unsignaled cells in other species.

W4154A Transcriptomic Analysis of *C. elegans* transgenic animals overexpressing human alpha-synuclein (A53T): Comparison to genes regulated in human Parkinson's Disease brain tissues. *C. Wang*[1], J. Peltonen[2], L. Heikkinen[3], G. Wong[1]. 1) University of Macau, Macau, MO; 2) University of Eastern Finland, Kuopio, Finland; 3) University of Jyväskylä, Finland.

Parkinson's Disease is a devastating neurodegenerative disorder characterized by loss of dopaminergic neurons in the *substania nigra pars compacta*. We modeled this disease by constructing a transgenic *C. elegans* strain overexpressing human alpha-synuclein gene with mutation A53T in dopaminergic and other neurons using a pan neuronal promoter. We isolated total RNA and performed RNA-seq transcriptomic analysis on young adult animals and compared the gene expression changes to controls. We observed 1793 genes up- and 92 down-regulated using a Bowtie-Cufflinks-Cuffdiff workflow. Gene set enrichment analysis using David 6.7 indicated that up-regulated annotation clusters included phosphatase activity (46 genes, $p<10^{-20}$), PapD-like (31 genes, $p<10^{-23}$), DUF856 (7 genes, $p<10^{-7}$) and down-regulated included (serine/threonine protein kinase (4 genes, $p<0.02$). Comparing the list of regulated genes from *C. elegans* to the top 11 genes related to human Parkinson's disease confirmed an overlap of 4 genes: DGKQ/GAK, diacylgycerol kinase (*dgk-1*), MAPT, microtubule-associated protein tau (*ptl-1*), SYT11/RAB25, synaptotagmin-11 (*snt-1*), and STK39, SPS1-related proline-alanine-rich protein (*gck-3*). Taken together, our results suggests

that *C. elegans* could be a useful model to identify gene expression changes in human Parkinson's disease and ultimately to understand the pathophysiology of this disease.

W4155B Overlapping microRNA networks during nematode development. *A. E. Kerscher*, J. Jo, K. Breving, J. Gordon, N. Feuer, E. Humes. Eastern Virginia Medical School, Norfolk, VA.

MicroRNAs (miRNAs) are a highly conserved class of non-coding RNAs that regulate essential cellular events such as proliferation and differentiation. The *Caenorhabditis elegans* (*C. elegans*) animal model provides a unique opportunity to determine how distinct groups of miRNAs, such as those belonging to the *lin-4* and *let-7* families, function in overlapping signaling networks during post-embryonic development. *lin-4* and *let-7* are well characterized and direct cell fate determination in *C. elegans* during the larval transitions and act as key regulators of temporal gene expression. Additional *lin-4* and *let-7* family members display overlapping expression patterns in the developing hypodermis and reproductive system in nematodes, and we hypothesize that combinations of miRNAs across these families (and sharing little sequence homology to one another) control common developmental events. Our deletion studies indicated that the *lin-4* homologue, miR-237, and the *let-7* family members, miR-48 and miR-84, function together likely with chromatin remodeling genes to direct cell cycle progression in the germline as well as formation of the egg-laying structures. Our work also suggested that members within the *lin-4* miRNA family, namely *lin-4* and *mir-237,* which share a common "miRNA seed", functionally compensate when tested in a *lin-4* loss-of-function *in vivo* rescue assay. These studies may provide insight into why mammalian homologues for *lin-4* and *let-7* are often targeted in a wide range of human cancers.

W4156C Identification of microRNAs that regulate ovulation in *C. elegans*. *Katherine Maniates*, Benjamin Olson, Jordan Brown, Tyler Crawford, Katalin Kenney, Allison Abbott. Marquette University, Milwaukee, WI.

MicroRNAs regulate many developmental and physiological processes in *C. elegans* including ovulation, a rhythmic process that occurs every 20 minutes in adult worms. Even though microRNAs are known to be necessary for ovulation, the individual microRNAs that regulate ovulation are still largely unknown. One challenge of this work is that microRNAs can function redundantly and many individual microRNAs mutants do not display observable phenotypes. We have taken several approaches to identify individual microRNAs that function in the process of ovulation. First, we have performed a synthetic sterility screen of microRNA mutants using knockdown of a "hub gene," *hmg 1.2* RNAi. On this sensitized genetic background, we identified five microRNAs as candidates to regulate ovulation in *C. elegans.* These candidates are being further analyzed to characterize their role in ovulation. Second, we have analyzed microRNAs that were identified from small RNA sequencing of RNA isolated from mature oocytes. One abundant family of microRNAs in the oocyte is the miR-44 family. It is composed of four miRNAs: *mir-44, mir-45, mir-61,* and *mir-247,* that share a common seed sequence and thus are predicted to regulate shared target mRNAs. Triple *mir-44* family mutants have significantly reduced ovulation rate and brood size, suggesting a role in regulating ovulation. *mir-44* and *mir-45* are within about 9kB of each other so double mutants were not able to be generated. Because miR-44 and miR-45 have identical mature miRNA sequences, we sought to obtain a double mutant using CRISPR. CRISPR was used to introduce a mutation in the *mir-45* gene in worms carrying a deleting in *mir-42/44.* This *mir-45 mir-42/44* double mutant is currently being analyzed to characterize ovulation defects. The goal is to identify pathways and targets regulated by specific microRNAs in the process of ovulation.

W4157A Investigating the role of KIN-20 in microRNA biogenesis, LIN-42 regulation and developmental timing. *Christiane Olivero*, Katherine Cascino, Laura Aseltine, Joseph Spina, Priscilla Van Wynsberghe. Colgate University, Hamilton, NY.

The *C. elegans* heterochronic pathway is composed of multiple proteins and microRNAs that regulate developmental timing. microRNAs are ~22 nucleotide RNAs that post-transcriptionally silence gene expression, and are thus essential in diverse biological processes. Previous work in our lab and others has shown that the heterochronic pathway member and circadian rhythm Period protein homolog, LIN-42, regulates microRNA biogenesis. Like other period proteins, levels of LIN-42 oscillate throughout development. In other organisms this cycling is controlled in part by phosphorylation and dephosphorylation events. KIN-20 is the *C. elegans* homolog of the *D. melanogaster* Period protein kinase *doubletime*. Worms containing a large deletion in *kin-20* develop slower and have a significantly smaller brood size than wild type *C. elegans*. Here we analyze the effect of KIN-20 on the expression of the canonical heterochronic miRNAs let-7 and lin-4. We find that let-7 and lin-4 levels are significantly decreased and that mRNA levels of the let-7 target *lin-41* are increased in *kin-20* mutant worms relative to wild type. Additionally, we find that primary let-7 and primary lin-4 levels are unchanged in *kin-20* mutant worms suggesting that KIN-20 impacts miRNA biogenesis downstream of miRNA transcription. Current work seeks to determine if these effects are dependent on LIN-42. To further explore the relationship of KIN-20 and LIN-42, we analyzed the effect of KIN-20 on endogenous LIN-42 expression. Based on the homologous system in *D. melanogaster*, we hypothesized that KIN-20 phosphorylates LIN-42 to trigger LIN-42 degradation. Surprisingly, we find that KIN-20 effects on LIN-42 differ depending on the isoform analyzed. Altogether these results help uncover the mechanisms by which these conserved circadian rhythmic genes interact to ultimately regulate rhythmic processes, developmental timing and microRNA biogenesis in *C. elegans*.

W4158B A conserved yet uncharacterized RNA binding protein modulates microRNA activity during *C. elegans* development. *A. Y. Zinovyeva*, M. Kranick, K. Nilges, M. Gulley. Kansas State University, Manhattan, KS.

MicroRNAs are small non-coding RNAs that post-transcriptionally regulate expression of many genes. MicroRNA activity is essential for animal development as alterations in microRNA expression and function have been associated with many developmental pathologies and diseases, making microRNAs of great interest as diagnostic and therapeutic targets. However, little is known about how microRNA function itself is modulated by specific developmental and physiological signals. We wish to understand how cellular factors may integrate these signals to modulate microRNA-mediated gene repression. Using proteomics approaches, we identified a conserved yet uncharacterized RNA binding protein, HRPK-1, as an Argonaute ALG-1 interacting factor. Loss of *hrpk-1* function results in a number of developmental phenotypes, including

defects in embryonic development, fertility, and organ morphogenesis, all phenotypes reminiscent of defects seen in specific microRNA mutants. Knockdown of *hrpk-1* by RNAi enhances the embryonic lethality associated with *mir-35-41* mutants, suggesting that *hrpk-1* function is required at least for miR-42 activity. RNAi knockdown of *hrpk-1* also enhances the cell fate defect observed in a reduction-of-function allele of a neuronal microRNA, *lsy-6*, implying that *hprk-1* similarly normally promotes lsy-6 microRNA activity. Interestingly, *hrpk-1* mutants showed no reduction in mature microRNA production, suggesting that HRPK-1 function may not be required for microRNA biogenesis. Because HRPK-1 has predicted RNA binding domains and appears to function downstream of microRNA biogenesis, we hypothesize that HRPK-1 may modulate microRNA activity by interacting with miRISC on target mRNAs.

W4159C Using *C. elegans* cuticle collagen genes to dissect temporal regulation of gene expression during development. *P. Abete Luzi*, D. M. Eisenmann. University of Maryland Baltimore County, Catonsville, MD.

The precise temporal control of gene expression is an essential aspect of metazoan development. After embryogenesis, the ecdysozoan nematode *C. elegans* goes through four larval stages (L1 - L4), molting its outer cuticle covering between each, before becoming an adult. The cuticle in each stage is unique, and the major components of the cuticle are nematode-specific cuticle collagen proteins, which are expressed from a large gene family in this species. Examination of modENCODE project RNAseq temporal developmental data showed that during *C. elegans* development a majority of cuticle collagen (*col*) genes (116/187) display a strong peak of expression in only one developmental stage. This set of temporally co-regulated similar genes provides a powerful system to study temporal regulation of gene expression. Our work is focused on a subset of *col* genes that peak during the L4 larval stage: *bli-1, col-38, col-49, col-63*, *col-138* and *col-175*. Transcriptional YFP reporters for these genes showed peaks of expression in the hypodermis during the L4 stage. Deletion analyses narrowed the necessary promoter regions to fragments of 262, 222 and 282 bp in *col-38*, *col-63* and *col-49*, respectively. In *C. elegans*, developmental timing is controlled by the heterochronic pathway of proteins and miRNAs. The most downstream effector of this pathway is LIN-29, a zinc finger transcription factor required for the larval-to-adult 'switch' in hypodermal cells. As *lin-29* was previously shown to regulate expression of an adult cuticle *col* gene, we investigated the role of *lin-29* in expression of our L4-specific *col* genes. We examined the effects of both *lin-29* loss- and gain-of-function on L4 *col* YFP transcriptional reporters as well as on endogenous *col* gene transcription levels, and found that LIN-29 is required for robust expression of *col* genes in the L4 stage, and sufficient for misexpression of L4-*col* genes at other developmental times. We also found that LIN-29 protein binds in gel shift assays to the smallest *col* gene promoter fragments necessary for *in vivo* expression. These fragments each contain several putative LIN-29 DNA binding motifs, and the requirement for these sites for *in vitro* binding and *in vivo* expression is being tested. Taken together, these results strongly suggest direct regulation of stage-specific *col* genes by LIN-29 during the L4 stage. In order to expand our work on the temporal regulation of gene expression during the L4, we are currently performing a genome-wide search for LIN-29 target genes using temporal misexpression of LIN-29 and RNAseq. Results will be reported.

W4160A Role of nuclear Argonaute proteins in the inheritance of acquired stress resistance in *C. elegans*. *E. Okabe*, S. Kishimoto, M. Uno, E. Nishida. Kyoto University, Kyoto, JP.

As organisms are constantly exposed to many environmental stresses, dealing with stresses is an intrinsic protective mechanism to adapt oneself to the environment. Through exposure to milder stresses, animals increase stress resistance and viability, and thereby live longer. In *Caenorhabditis elegans*, it has been reported that exposure of adult worms to mild stresses can increase stress resistance. Recently, it has been becoming clear that the acquired stress resistance in the parental generation can be inherited to the next generation. However, the molecular mechanisms underlying the inheritance of acquired stress resistance remain largely unknown. Because endogenous small RNAs have been shown to play an important role in transgenerational epigenetic inheritance, we focused our attention on nuclear Argonaute proteins whose functions are essential for transcriptional regulation by endogenous small RNAs. We exposed larvae to hyperosmosis, and then measured the resistance to proteotoxity. Our measurements showed that exposure to hyperosmosis increased the stress resistance, and that the increased stress resistance in the parental generation was inherited to the offspring. We next knocked down each of the two nuclear Argonaute proteins, *hrde-1* and *nrde-3*, in the parental generation. Either *hrde-1* RNAi or *nrde-3* RNAi resulted in suppression of the increased stress resistance in the offspring. Our results suggest that nuclear Argonaute proteins play a role in the transgenerational inheritance of acquired stress resistance. We are now examining underlying mechanisms in more detail.

W4161B The effects of different food types on the reproductive physiology of *C. elegans*. *S. Mishra*, K. Marbach, E. Allen, J. Alcedo. Wayne State University, Detroit, MI.

Different aspects of an animal's life, like development, growth and reproduction, are directly influenced by the quality of its food. In the worm *Caenorhabditis elegans*, different types of food have been shown to affect different physiological processes, such as longevity, feeding and reproduction (Maier *et al*., 2010). For example, *C. elegans* grown on two different strains of *E. coli* bacteria (CS180 and OP50) show marked differences in their reproductive patterns. Worms grown on CS180 have a smaller brood size compared to worms grown on OP50. However, the animals on CS180 have faster rates egg-laying of as compared to animals on OP50. Currently, we are determining the mechanism(s) through which food quality could alter an animal's rate of egg-laying. Since egg-laying behavior is mediated by the amine neurotransmitter serotonin, we are also investigating how food quality affects serotonin signaling in these animals. Thus, we will use both molecular genetics and metabolomic approaches to define the metabolites/molecules present in the bacterial food sources, which are responsible in altering the reproductive physiology of *C. elegans.*

Maier, W., Adilov, B., Regenass, M., and Alcedo, J. (2010). A neuromedin U receptor acts with the sensory system to modulate food type-dependent effects on *C. elegans* lifespan. PLoS Biol *8*, e1000376.

W4162C Fluorescent beads are a versatile tool for staging *C. elegans* in different life histories. *I. nika*, T. Gibson, R. Konkus, X. Karp. Central Michigan University, Mount Pleasant, MI.

C. elegans life history is dependent on environmental cues transduced through several signaling pathways. In favorable environmental conditions *C. elegans* develops continuously through four larval stages before molting into the adult stage. In contrast, adverse environmental conditions promote entry into the stress resistant dauer larva stage immediately following the second larval molt. Dauer larvae possess distinct properties including cellular and developmental arrest, extended lifespan, and discontinued feeding. If environmental conditions improve, dauer larvae recover to post-dauer L3 larvae, which are developmentally identical to continuously developing L3 larvae. Precise staging of larvae developing through either continuous or dauer life histories is essential for the study of development and/or dauer-related processes. Here, we describe a staging method taking advantage of the inability of dauer larvae and molting larvae to feed. Fluorescent beads are added to the bacterial food source, and dauer or molting larvae are identified by a lack of beads within their digestive tract. Bead-lacking worms are sorted using a dissecting microscope or a wormsorter. We show that lack of beads correlates with two molting markers: lack of pharyngeal pumping, and expression of *mlt-10::GFP-pest.* We then describe how this assay can be used to isolate dauer larvae formed by any of three common methods: starved plates, exogenous pheromone, and dauer-constitutive mutations. Lack of beads correlates well with other known markers of dauer formation, including greatly reduced pumping rate, presence of dauer alae, and SDS resistance. We find that using beads rather than SDS-resistance to identify dauer larvae enables the recovery of SDS-sensitive mutants, including cuticle mutants and partial dauer larvae formed by mutations within the dauer formation pathway. This method therefore provides a simple, transgene-free way to distinguish particular stages during development through continuous or dauer life histories.

W4163A Sex-specific maturation of the *C. elegans* nervous system. *H. Steinert*, D. Portman. University of Rochester, Rochester, NY.

As animals transition into adulthood, males and females undergo sex-specific developmental changes that affect both morphology and behavior to maximize fitness. Juveniles primarily adopt new behaviors upon maturation through modification of existing neural circuits, which must occur at the appropriate time during development. In the *C. elegans* nervous system, most neural circuits are fully formed by the L3 larval stage; however, there are a few examples of neurons with delayed maturation. One is that the embryonically derived HSNs generate synapses onto the vulval muscle at the L3 and L4 larval stages. In addition, several existing neural circuits appear to undergo significant modulation through gene expression changes, particularly in males, during the juvenile-to-adult transition. For example, juvenile males and hermaphrodites have similar levels of the chemoreceptor *odr-10* in the sensory neuron AWA; however, upon maturation males specifically downregulate expression of this chemoreceptor. Similarly, males upregulate expression of *srj-54* in the interneuron AIM during this transition. These gene expression changes likely mediate the activation of adult behaviors; however, it remains unclear how their onset is regulated. In nematodes, it is known that the heterochronic pathway controls developmental timing by regulating stage specific events. Although this pathway has been carefully characterized in seam cells, its functions in the nervous system are not well understood. We are using *odr-10, srj-54,* and other genes as molecular markers for nervous system maturity, allowing us to investigate whether the heterochronic pathway regulates nervous system maturation. Surprisingly, our results suggest that several important heterochronic genes, such as *daf-12 and lin-41*, may not be important for this process. However, we find that *lep-5*, a newly identified heterochronic gene, is essential for juvenile-to-adult changes in the expression of *odr-10* and *srj-54*. Thus, a previously uncharacterized branch of the heterochronic pathway may be important for developmental timing in the nervous system.

W4164B FAX-1 and UNC-42 transcription factors regulate developmental arrest in *C. elegans*. *Bruce Wightman*[1], Emily Bayer[1,2], Sheila Clever[1]. 1) Muhlenberg College, Allentown, PA; 2) Columbia University, New York, NY.

The *fax-1* nuclear hormone receptor and *unc-42* homeobox gene control interneuron identities in *C. elegans*. *fax-1* is the ortholog of *unfulfilled* in *Drosophila* and PNR/NR3E3 in vertebrates, where it functions in the development and function of mushroom bodies and photoreceptors, respectively. The *fax-1* and *unc-42* transcription factors function in specifying the identities of an overlapping subset of nematode interneurons, including the command interneurons AVA and AVE, which function in coordinated movements. Both genes are required for the expression of neuron-specific genes, including glutamate receptors subunits, and axon pathfinding.

Mutations in both *fax-1* and *unc-42* cause an incompletely-penetrant slow-growth phenotype that arises from temporary arrest after hatching at the L1 stage. L1 arrest has been shown to be controlled by the insulin-like signaling pathway that also controls dauer formation and longevity. The *daf-2* insulin receptor is a primary mediator of insulin signaling in *C. elegans.* Strong *daf-2* mutations cause L1 arrest, while weak *daf-2* mutations cause dauer-arrest. Both *fax-1* and *unc-42* mutations cause a fully-penetrant L1 arrest in combination with a weak *daf-2* mutation. The L1 arrest can be reversed by a mutation in the *daf-16* forkhead transcription factor, which functions downstream of *daf-2*. These observations indicate that the *fax-1* and *unc-42* transcription factors may function in insulin-signaling or another pathway that controls developmental progression. Given that both genes are required for the development of a limited set of interneurons, these experiments suggest a previously unappreciated role for interneuron function in regulating developmental temporal progression and arrest. *Supported by NIGMS.*

W4165C Dystrophin interactors in worms and flies. *K. Edwards*, S. Goel, A. Rodriguez, L. Barickman, M. Villarreal, B. Rodemoyer, A. Vidal-Gadea. Illinois State Univ., Normal, IL.

Duchenne muscular dystrophy (DMD) is a fatal genetic disorder caused by mutations in the dystrophin gene and affecting up to one in 3500 males. Understanding the role of dystrophin (Dys) in the etiology of DMD will benefit from a comprehensive approach combining the individual advantages of multiple model systems. Therefore we are developing a pipeline to compare Dys interactor function in *C. elegans* and *Drosophila*. Lack of dystrophin in *C. elegans* leads to impaired burrowing, muscle decline, and death. In the DMD suppressor strain JPS518

(Beron et al. 2015; Genes, Brain & Behavior 14:357), one such interacting mutation displays large "blooms" of ectopic f-actin accumulation at the termini of the body wall muscles in response to muscle challenge. This suggest a novel mechanism for the restoration of muscle function in dystrophic worms. In Drosophila, Dys has been shown to be essential for two developmental events, the correct specification of the wing crossveins and the elongation of the egg during late oogenesis. Both phenotypes extend to new Dys insertion alleles from the Drosophila Gene Disruption Project. A GFP protein trap in the endogenous Dys locus shows that Dys has relatively low abundance and is very specifically localized at the basal side of epithelia such as the egg chamber follicle cells (as in Schneider et al. 2006; Dev. 133:3805). Dys-GFP accumulates laterally only in certain large cells, e.g., the egg chamber nurse cells and the salivary gland. Dys-GFP signal shows diverse, non-uniform patterns on the membrane; in the oocyte follicle cells it is circumferentially banded like actin. The Dys phenotypes and distributions allow for sensitive genetic and/or localization assays of candidate interactors such as the adaptor protein Capon/NOS1AP (*C. elegans* DYC-1). The Drosophila ortholog of Capon (CG42673) was identified and found to have conserved PTB and coiled coil domains, indicating participation in a protein complex, but it lacks the C-terminal Nitric Oxide Synthase binding region known in vertebrates. Capon LOF allelic combinations are viable and lack the short-egg phenotype seen in Dys mutants, but they do have defects in wing venation. The results indicate that a comparative approach will provide greater insights into the signaling and structural roles of the Dys complex and its functional partners.

W4166A Comparative genomics reveals novel genes associated with sensory cilia. *B. P. Piasecki*[1], T. Sasani[1], B. O'Flaherety[1], J. Henriksson[2], E. A. De Stasio[1], P. Swoboda[2]. 1) Lawrence University, Appleton, WI; 2) Karolinska Institute, Stockholm, Sweden.

A comparative genomics-based screen was conducted to identify evolutionarily conserved ciliary genes that facilitate sensory-specific roles. Using reciprocal BLAST analyses, the genomes of organisms that do not make cilia (the plant *Arabidopsis thaliana* and the yeast *Saccharomyces cerevisiae*) and that retain motile but not sensory cilia (the moss *Physcomitrella patens*) were subtracted from the genomes of organisms that have retained sensory cilia (the worm *Caenorhabditis elegans* and the alga *Chlamydomonas reinhardtii*). These analyses revealed a list of approximately 300 genes that are found exclusively in organisms with sensory cilia but not motile cilia. Importantly, over 10% of the genes on this list have previously been implicated in sensory cilia-specific roles, thus providing numerous internal positive controls, which demonstrates that this list is enriched with sensory-specific ciliary genes. A subset of uncharacterized candidate genes are currently being studied in *C. elegans*, which retains cilia exclusively on a set of neurons termed ciliated sensory neurons (CSNs). We are currently generating a number of promoter- and gene-to-green fluorescent protein (GFP) fusion constructs in order to determine the expression and localization patterns of the proteins encoded by these genes. Two of these candidate genes, which are found in worms (*C. elegans*) and algae (*C. reinhardtii*) but not in moss (*P. patens*) have been termed *wam-1* and *wam-2*, respectively. Expression of *wam-1* appears to be localized exclusively in the support cells of ciliated dopaminergic neurons, while expression of *wam-2* has yet to be fully characterized. Our analyses have successfully revealed novel genes involved in ciliary sensory-specific processes in animals.

W4167B Coordinating microtubule organization with cell cycle state. *Maria Sallee*, Jessica Feldman. Stanford Univ., Palo Alto, CA.

Microtubule organizing centers (MTOCs) generate specific arrangements of microtubules that are essential for many cellular functions, including division, polarization, and transport. Different subcellular sites serve as the MTOC to accommodate these processes; dividing animal cells establish an MTOC at the centrosome, while many differentiated cells designate a non-centrosomal site as the MTOC. A conflict arises when differentiated cells divide — the centrosome must be re-established as the MTOC for mitosis to occur. Regulating this switch in the subcellular site of the MTOC (the "MTOC switch") is important for controlling proliferation in epithelial cells, and a dysregulated switch may contribute to disease states such as cancer. We are using the developing *C. elegans* intestine as a model to understand the mechanistic nature of this MTOC switch. In polarized embryonic intestinal cells, the site of the MTOC switches very stereotypically from the membrane to the centrosome as they divide, and then back to the membrane as they exit mitosis. This binary MTOC switch offers a simple and elegant system to study how the MTOC location is regulated by and coordinated with the cell cycle. We hypothesize that cell cycle genes directly control MTOC location, and that MTOC location is a critical determinant in regulating a cell's potential to divide. Using fluorescently-tagged markers, we can observe the MTOC switch as the cell cycle progresses in real time, and have determined that the membrane switch occurs in G1, while the centrosome switch occurs in G2/M phase. Our hypothesis predicts that cell cycle regulators must interface with MTOC components at some level to coordinate the MTOC location with cell cycle state. We are now testing several candidate regulators of the MTOC switch, including a surprising candidate, the microtubule-severing enzyme *mei-1*/Katanin. In *mei-1(0)* embryos, intestinal cells initially undergo the membrane switch, but soon after, they aberrantly activate the centrosome switch and divide. Intestinal cell number is normal prior to the E16 intestinal stage, suggesting that the additional intestinal cells are not due to early cell fate specification defects. The centrosome switch and division defects are rescued by GFP-MEI-1, and also observed in mutants for the other subunit of the Katanin complex *mei-2*, suggesting that the defects are caused specifically by loss of the Katanin complex. MEI-1 localizes to the membrane MTOC, suggesting a potential role at the membrane in maintaining the MTOC state. In addition to *mei-1*, we are currently investigating several candidates and carrying out an unbiased genetic screen to identify additional MTOC regulators. This work will help reveal the molecular mechanism underlying the coordination of MTOC location with cell cycle state.

W4168C Mechanisms of SYS-1/β-catenin centrosomal localization in early embryonic blastomeres. *J. W. Thompson*, Bryan Phillips. University of Iowa, Iowa City, IA.

Asymmetric cell division, the unequal distribution of cell fate determinants between daughter cells, is a critical system underlying the development and maintenance of the varied tissue types of a multicellular organism. Despite widespread utilization of such divisions, the mechanisms responsible for induction of asymmetry are less understood due to the complex, pleiotropic, and often functionally redundant signaling systems involved. Throughout *C. elegans* development, the Wnt/β-catenin asymmetry pathway induces the asymmetric distribution of Wnt signaling components to polarize a mother cell and therefore differentially regulate Wnt target genes in its daughter cells. For instance,

a proper Wnt signaling response results in accumulation of cytoplasmic SYS-1/b-catenin in the proximal 'signaled' cell, which, along with co-activator POP-1/TCF, activates genes to induce the corresponding cell fate. Despite its asymmetric regulation immediately post-division, cytoplasmic SYS-1 localizes symmetrically to mitotic centrosomes. Recent data from our lab indicate that centrosomal localization of SYS-1 serves as a clearance mechanism to increase the robustness of Wnt-mediated polarity. However, the method of SYS-1 trafficking to and accumulation at the centrosome is unknown. In the early embryo, this centrosomal localization of the SYS-1 is dependent on the centrosomal scaffolding protein RSA-2. When SYS-1 is prevented from loading to the centrosome by loss of RSA-2, it accumulates in the approximate region of kinetochore microtubules. This localization suggests that SYS-1 may be directly transported to centrosomes along microtubules via the action of molecular motors. Specifically, we focused on dynein and dynactin components as the primary minus-end directed motor machinery. We conducted an RNAi and chemical screen specifically aimed at depleting these microtubules and microtubule transport proteins and quantified relative and proportionate SYS-1 centrosomal accumulation. This screen identified several dynein subunits that have a role in proper centrosomal localization of embryonic SYS-1/b-catenin and its regulators. Further, the preliminary data from microtubule-destabilizing and ATP-depleting chemical treatment indicate that both ATP and microtubules are important for SYS-1 centrosomal localization. Together, these results suggest an active role for the multimeric dynein/dynactin cargo binding complex in SYS-1/b-catenin regulation and signaling status.

W4169A The effects of luteolin on the V-ATPase and the acidification of the FB-MOs in *C.elegans* sperm. *Melissa Henderson*, Kenneth Dexter, Marybeth Babos. Lincoln Memorial University-DeBusk College of Osteopathic Medicine, Harrogate, TN.

The V-ATPase is a 14 subunit complex responsible for the acidification of intracellular vesicles and organelles. The complex is also found on the surface of osteoclasts involved in bone resorption during osteoporosis and overexpressed in some tumors. The connection of the V-ATPase with these diseases has launched a need to find inhibitors of this complex as potential therapeutics. During spermatogenesis in *C.elegans* the fibrous body-membranous organelles (FB-MOs) act as secretory vesicles responsible for the delivery of proteins to the surface of the sperm prior to fertilization. The FB-MOs undergo acidification in spermatids facilitated by the V-ATPase. This necessary change in pH can be indicated by the use of LysoSensor Blue (Molecular Probes) staining and the spermatids ability to mature into mature spermatozoa. Here we have established a method to screen potential inhibitors of the V-ATPase complex. Luteolin is a flavonoid compound found in vegetables, fruits, and medicinal herbs. We have examined the inhibitory effects of luteolin on the V-ATPase complex in the sperm in *C.elegans*. Growth assays were used to examine the toxicity of the compound. In addition to the staining for acidification of the FB-MOs, morphology of the germ cells undergoing spermatogenesis as well as DAPI staining allowed for the comparison to *spe* mutants. This novel approach to screening inhibitors of the V-ATPase will facilitate the screening for new therapeutic compounds.

W4170B The calponin family member CHDP-1 promotes membrane expansion and interacts with Rac/CED-10 to regulate protrusion formation. *Y. l. Guan*. Chinese Academy of science, Beijing, CN.

Eukaryotic cells extend a variety of surface protrusions to direct cell motility, which is mediated by coordinative actions between plasma membrane and underlying actin cytoskeleton. Here, we found that with its amphiphilic motif, the single calponin homology (CH) domain-containing protein CHDP-1 anchors on plasma membrane and induces membrane deformation in *C. elegans*. Through its CH domain, CHDP-1 associates with the small GTPase Rac1/CED-10, which is a key regulator for actin cytoskeleton arrangement. CHDP-1 preferably binds to the GTP-bound active form of CED-10 protein and the membrane localized GTP-CED-10 is decreased when CHDP-1 is removed. Thus, by coupling membrane expansion to the Rac1-mediated actin dynamics, CHDP-1 promotes membrane protrusion *in vivo*.

W4171C *Caenorhabditis elegans* extracellular matrix proteins regulate polycystin localization/activity and cilia integrity. *Deanna Michele De Vore*, Maureen Barr. Rutgers University, Piscataway, NJ.

PKD2 encodes a transient receptor potential polycystin (TRPP) channel receptor protein found in primary cilia of mammalian cells and sensory cilia of *C. elegans* neurons. In humans, PKD2 mutations result in Autosomal Dominant Polycystic Kidney Disease (ADPKD). Given the ancient and evolutionarily conserved role for polycystin-2 in cilia, we are using *C. elegans* as a model to identify new genes required for ciliary receptor localization. We recently found that extracellular matrix components are important for *C. elegans* PKD2 localization and function. ECM formation, secretion, and integrity have been shown to be a primary factor in ADPKD (Mangos 2010). Transmembrane and ECM proteins such as cadherins and galectins act in cilium retraction and elongation and also play a role in cell-to-cell junction signaling via the ECM (Seeger 2012, Rondanino 2011).

mec-1, mec-5, and *mec-9* encode ECM components that play a role in mechanosensation and degenerin/epithelial sodium channel (DEG/ENaCs) localization in non-ciliated touch receptor neurons (Du 1996, Emtage 2004). *mec-1* and *mec-9* encode proteins with multiple EGF and Kunitz domains; *mec-5* encodes a collagen (Du1996, Emtage 2004). I found that the ECM encoding genes *mec-1, mec-5,* and *mec-9* also regulate polycystin localization in male-specific ciliated sensory neurons. I further show that these proteins regulate mating behaviors and cilia structure. I am currently exploring their roles in localization of other ciliary proteins and determining the mechanisms by which these ECM proteins. This study may provide insight on how extracellular matrix proteins contribute to ciliary localization of sensory receptors like PKD-2, and advance the understanding and expand the options for treatment of ciliopathies such as ADPKD.

W4172A Intermediate filaments EXC-2/IFC-2 and IFA-4 Maintain Tube Structure of the Excretory Canal of the nematode *C. elegans*. *H. Al Hashimi*[1], M. Buechner[2]. 1) The University of Kansas, Lawrence, KS; 2) The University of Kansas, Lawrence, KS.

Seamless single-celled tubules form the excretory canals of the nematode *Caenorhabditis elegans*. These canals are narrow and extend over the whole length of the worm, and are an attractive model to understand how biological tubes maintain diameter and shape. In *C. elegans*, loss-of-function mutations in any of a set of *exc* genes cause the excretory canal lumen to swell into large fluid-filled cysts. The *exc-2* mutant

worm shows one the most severe phenotypes among the *exc* genes. In order to identify the *exc-2* gene, whole-genome sequencing was performed on *exc-2* mutant allele *rh90*. The results suggested a frameshift mutation in the intermediate filament gene *ifa-4*. Knockdown of *ifa-4* gene mimics the Exc-2 cystic-canal phenotype, and the strain RB1483 (Δ*ifa-4*(*ok1734*)) showed a similar cystic phenotype. Unexpectedly, injection of the wild-type *ifa-4* gene did not rescue the *exc-2* mutant; worms and mutants of the two genes genetically complemented each other, which surprisingly confirmed that *ifa-4* and *exc-2* are not the same gene. Next, whole-genome sequencing was performed on three additional *exc-2* alleles (*rh105*, *rh209*, and *rh247*), which provided greater resolution and confidence in identifying the gene. Results showed that the non-essential cytosolic intermediate filament gene *ifc-2* has mutations in all of the four alleles that were sequenced. The *ifc-2* gene has nonsense mutations in the alleles *rh209* and *rh247*, while alleles *rh90* and *rh105* have deletions among coding regions of the gene. *ifc-2* is a relatively large gene (~13kb), with four isoforms: C and D take up the first and second halves of the gene, respectively, while isoforms A and B each cover almost all of the exons. Knocking down any combination of isoforms containing both A and B showed a phenotype similar to Exc-2 cysts, while knockdown of isoform A by itself showed a much milder phenotype. We have rescued the *exc-2* gene by injecting PCR product contains full length of the *ifc-2* gene into *exc-2* mutant worms.

EXC-2/IFC-2 and IFA-4 join the previously discovered role (Labouesse lab) of IFB-1 in regulating the diameter of a model narrow seamless tube. Intermediate filaments could play important roles in other narrow seamless tubes as well. We are now investigating the time and position of expression of *ifa-4* and *ifc-2* isoforms to determine the interactions that form the distinctive shape of the excretory canals.

W4173B Genetic Analysis in NimA-Related Kinase Pathways in *C. elegans*. *D. S. Fay*, Braveen Joseph, Vladimir Lazetic. Univ Wyoming, Laramie, WY.

The family of NimA-related kinases (NEKs) are highly conserved in eukaryotes where they have been reported to regulate a number of diverse processes including mitosis, cytokinesis, DNA repair, ciliogenesis, and inflammation. Correspondingly, misregulation of NEKs have been linked to a variety of diseases including cancer and renal and cardiac disorders. Nevertheless, the targets of NEKs, as well as the components of NEK signaling pathways, remain largely unknown. In contrast to humans, which encode 11 NEK family members, the *C. elegans* genome encodes 4 family members (NEKL-1/NEK9, NEKL-2/NEK8, NEKL-3/NEK6/7, and NEKL-4/NEK10). We recently reported a novel function for NEKL-2 and NEKL-3 in regulating the completion of *C. elegans* molting during larval development. Our published and recent studies indicate that incomplete molting stems, at least in part, from defects in endocytosis in the apical epidermis of *C. elegans* larvae, thus implicating NEKs in process associated with intracellular trafficking. To gain further insight into the molecular, cellular, and developmental functions of NEK kinases, we have undertaken a number of approaches including genetic analysis. Using CRIPSR/Cas9 methods, we have used an iterative approach to generate a range of loss-of-function (LOF) alleles of *nekl* kinases We find that weak hypomorphic alleles in *nekl-2* and *nekl-3*, which display no defects as single mutants, are synthetically lethal, leading to near uniform larval arrest in *nekl-2; nekl-3* double mutants. We reasoned that *nekl-2; nekl-3* may provide an optimal background for identifying suppressors of NEKL-associated molting defects given that the individual *nekl* alleles are weak LOFs and that suppression of lethality could be incurred by mutations that affect either the NEKL-2 or NEKL-3 pathways or both. Using a semi-clonal F1 screen, we were successful in identifying ~12 suppressor mutations of varying strengths and we will describe progress on their molecular identification. We will also describe a non-clonal screen, that makes use of a counter-selectable marker in *C. elegans*, to identify additional *nekl-2; nekl-3* suppressors. This method could be adapted to any suppressor screen where the lethal phenotype of the parental starting strain is incompletely penetrant. Finally, we will discuss focused RNAi approaches to directly identify protein kinases and protein phosphatases that modulate signaling by NEKL kinases.

W4174C O-GlcNAc cycling and mitochondrial oxygen consumption. *M. P. Mahaffey*, J. L. Sacoman, P. M. Berninsone. University of Nevada, Reno, NV.

O-linked-β-N-acetylglucosamine (O-GlcNAc) modified proteins are critical in myriad cellular processes and functions. Abnormal O-GlcNAcylation is associated with a spectrum of diseases, including Alzheimer's disease, cancer, cardiovascular disease, and diabetes. Mitochondrial protein O-GlcNAcylation is emerging as a key regulator of cellular energetic metabolism, redox signaling and cell survival pathways, but the mechanisms involved are largely unknown. O-GlcNAc transferase (OGT) is the enzyme responsible for the addition of O-GlcNAc to target proteins while O-GlcNAcase (OGA) catalyzes the removal of the modification from target proteins. OGT and OGA are encoded by single genes in *C. elegans* (*ogt-1* and *oga-1*, respectively). Null alleles of *ogt-1* and *oga-1* are viable and fertile, unlike knockouts of OGT in mouse that result in embryonic lethality. We hypothesize that O-GlcNAc cycling mediated by OGT and O-GlcNAcase play a role in regulating mitochondrial metabolism and morphology. To that end, we measured oxygen consumption rate (OCR), a proxy for mitochondrial oxidative phosphorylation function, in N2, *ogt-1* and *oga-1* null mutants. OCR was measured using the Seahorse Bioscience XF^{e} 24 Extracellular Flux Analyzer and normalized by number of worms for each individual well. Our results suggest that altered O-GlcNAc cycling reduces oxygen consumption by negatively impacting mitochondrial oxidative metabolism. It is still unknown if these reductions in OCR are caused by reduction in mitochondria content or reduced mitochondrial function. These results will add to the knowledge of how O-GlcNAcylation modulates mitochondrial health and function.

W4175A Male Chemosensory Pathways that Modulate Sperm Navigation Performance. *H. D. Hoang*, M. A. Miller. University of Alabama at Birmingham, Birmingham, AL.

The molecular mechanisms by which environmental cues influence reproductive success are not well understood. In this study, we identify a genomic cluster of serpentine receptor B (SRB) chemosensory receptors that modulate sperm motility performance within the hermaphrodite reproductive tract. SRB chemoreceptors signal via GOA-1 and EGL-30 G protein pathways in male ciliated amphid sensory neurons, including ASI and ASK. SRB signaling is both necessary and sufficient in amphids to modulate sperm motility performance. The neuropeptide ligands FLP-

21 and FLP-18, and their receptor NPR-1, act together with SRB chemoreceptors to transduce signals to the testis. We show that SRB signaling promotes metabolic and cytoskeletal gene expression during spermatogenesis. Changes in sperm mitochondrial respiratory chain complex subunit mRNA levels affect sperm velocity and reversal frequency, impairing their ability to respond to guidance cues called prostaglandins. These results show that chemosensation has a profound impact on sperm function, with each sex manipulating sperm performance to optimize their individual reproductive success. Current efforts aim to better understand the sensory cues that control SRB pathways and evolution of the SRB circuits.

W4176B Three conserved tetraspanin proteins positively modulate BMP signaling in *C. elegans*. *Zhiyu Liu*, Herong Shi, Jun Liu. Department of Molecular Biology and Genetics, Cornell University, Ithaca, NY 14853.

The bone morphogenetic protein (BMP) signaling pathway plays essential roles in multiple developmental and homeostatic processes in metazoans. While the core BMP pathway members are well studied, much is needed for understanding the mechanisms involved in the spatiotemporal regulation of BMP signaling in vivo. We recently identified three highly conserved tetraspanin proteins, TSP-12, TSP-14 and TSP-21, as positive modulators of the BMP signaling pathway in *C. elegans* (Liu et al., 2015). *tsp-21(0)* single mutants or *tsp-12(0); tsp-14(0)* double mutants exhibit defects caused by reduced BMP signaling, including a small body size, reduced expression of a BMP signaling reporter, the RAD-SMAD reporter, and suppression of the mesodermal patterning defects of mutants in the *C. elegans* Schnurri homolog SMA-9. While all three tetraspanins are expressed and function in the signal-receiving cells to promote BMP signaling, TSP-21 appears to function in parallel with TSP-12 and TSP-14, because *tsp-12(0); tsp-14(0) tsp-21(0)* triple mutants are smaller than either *tsp-21(0)* single mutant or *tsp-12(0); tsp-14(0)* double mutant. We have found that TSP-21 is plasma-membrane localized and that this localization is not affected in *tsp-12(0); tsp-14(0)* double mutants. We are currently further dissecting the functional relationship among these three tetraspanin proteins. TSP-21 is orthologous to human TSPAN4, TSPAN9 and CD53. TSP-12 and TSP-14 are paralogous to each other and homologous to human TSPAN5, TSPAN10, TSPAN14, TSPAN15, TSPAN17 and TSPAN33. We speculate that these human tetraspanin proteins may also function in modulating BMP signaling.

Liu, Z et al. (2015) Promotion of Bone Morphogenetic Protein Signaling by Tetraspanins and Glycosphingolipids. *PLoS Genetics* 11(5):e1005221.

W4177C AMPK-related kinase UNC-82 has genetic and probable physical interactions with paramyosin. *NT. Schiller*, C. Duchesneau, L. Lane, E. Manzon, P. Hoppe. Western Michigan University, Kalamazoo, MI.

C. elegans striated muscle requires the serine/threonine kinase UNC-82 for proper organization of myosin filaments. Little is known about the targets of UNC-82 kinase, and the mechanism that regulates its activity has yet to be determined. Worms homozygous for *unc-82(0)* exhibit bright amorphous birefringent patches that contain the thick filament proteins myosin and paramyosin (Waterston et al., 1980; Hoppe et al., 2010). Our immunohistochemical analysis of *unc-82* mutants that contain missense mutations in the kinase domain revealed distinctive ectopic birefringent paramyosin accumulations at the ends of muscle cells that are not found in the null mutant. Transgenes in which the missense *unc-82(e1220)* mutation is tagged with GFP/RFP show normal localization to the M-line in a wild-type background, but in the *unc-82* null colocalize with birefringent accumulations at the ends of muscle cells. Driving expression of a heat-shock-inducible paramyosin::GFP in young adults showed that newly made paramyosin forms distinctive accumulations at the ends of cells in the missense mutant, consistent with the hypothesis that newly made paramyosin physically associates with UNC-82 protein. Dose-dependent synthetic lethality was observed between UNC-82 and mutations in paramyosin. Expression of UNC-82::GFP in the paramyosin mutant *unc-15(e73)* revealed that UNC-82 was recruited to the ectopic paramyosin-containing aggregates of this mutant, altering aggregate morphology and reducing motility and viability. UNC-82::GFP is recruited to paramyosin-containing aggregates formed in mutants that affect the M-line proteins UNC-89/obscurin, UNC-98/Zn-finger and UNC-96. We further explored physical interactions between UNC-82 and other M-line or thick-filament proteins by analyzing single and double mutant strains in which myosin, paramyosin or UNC-82 is abnormally localized within muscle cells, and determining which proteins are recruited to the aberrant structures. The phenotype of *unc-82; unc-98* double mutants closely resembles that of unc-*82* single mutants, suggesting that the two proteins act in a single pathway to organize paramyosin. The *unc-89(su75);unc-82(e1220)* double mutant is viable, exhibiting an enhanced phenotype compared to either mutant alone while the *unc-89(su75);unc-82(0)* double is not viable, indicating the two proteins are acting in parallel pathways. Our results suggest that UNC-82 physically interacts, either directly or indirectly, with paramyosin, but not myosin A, UNC-89 or the UNC-98/Zn finger protein. Our data are consistent with the model that UNC-82 kinase is epistatic to UNC-98 and is required for regulation, localization and incorporation of paramyosin into the thick filaments of the contractile apparatus.

W4178A A Tale of Two SNPs: Genetic Analysis of the Dopamine Transporter Structure and Function in DAT-1 Coding Variants Derived from the *C. elegans* Million Mutation Project. *Phyllis Freeman*[1], Emmanuel J. Jackson[1], Peace O. Odiase[1], Bailey Monroe[1], Winston W. Jackson[1], Ciara D. Elie[1], Angeline Eugene[1], Chelsea L. Snarrenburg[2], Jane Wright[2,3], Sarah M. Sturgeon[2], Sarah B. Robinson[2], Randy D. Blakely[2,3]. 1) Fisk University, Nashville, TN; 2) Vanderbilt University, Nashville, TN; 3) Vanderbilt University Medical Center, Nashville, TN.

The dopamine (DA) transporter (DAT) is a polytrophic, membrane protein that utilizes the co-transport of Na^+ and Cl^- ions to energize the rapid re-uptake of DA from the synapse in order to terminate extracellular DA signalling and facilitate re-release. As worm synaptic structure in general, and the expression of DAT in particular, are conserved across phyla, studies with the orthologous *Caenorhabditis elegans* protein model provide an ideal opportunity to probe fundamental questions of transporter structure and function in an *in vivo* setting using powerful forward and reverse genetic screens. The Million Mutation Project (MMP, http://genome.sfu.ca/mmp/) represents a library of ~2,000 mutagenized worm strains where sequencing at a depth of 15X genome coverage reveals the presence of, on average, ~9 new non-synonymous alleles per gene,whose characterization can reveal novel links to protein structure and function. Thirteen such coding variants are

present in the MMP. We have initiated the functional characterization of these variants, focusing initially on five lines that bear amino acid changes (D8N, P9L, M20T, P596S, P609S) at highly conserved locations and/or that are associated with regions suspected to confer/support DAT activity or regulation based on mammalian DAT studies. To date, we have confirmed the behavior of four of these lines consistent with DAT-1 loss of function, assessed by the presence of Swimming-induced paralysis (*S*wip). Results from the successful genetic cross of mutant worms with *cat*-2 tyrosine hydroxylase (TH, cat-2) loss of function mutant lines and the introduction of MMP mutations into a GFP-DAT-1 expression construct via site-directed mutagenesis of the wildtype *dat*-1 will be used to determine the impact of *dat*-1 missense alleles on *in vivo* DAT function and distribution in DA neurons. Supported by NIH award MH095055 (RDB) and NSF award 1505176 (PF).

W4179B The *Caenorhabditis elegans* excreted-secreted protein fraction is enriched in innate immunity related proteins. *P. M. Berninsone*, V. Arinze, J. Sacoman, F. Feyertag, D. Alvarez-Ponce. Univ Nevada, Reno, NV.

We have developed a protocol to isolate an excreted-secreted protein (ESP) fraction by collecting and concentrating the spent media from synchronized large-scale *C. elegans* cultures. Using high-throughput liquid chromatography/ mass spectrometry analysis, we discovered that the *C. elegans* ESP fraction contains C-type lectins domain-containing proteins, proteases, antimicrobial proteins and lysozymes. Many ESP protein components have been previously identified as transcriptionally upregulated upon pathogen exposure, which agrees with the innate immune response role assigned to some of these proteins. In addition, many uncharacterized proteins were found in this preparation, including nematode-specific proteins. Ongoing efforts include the analysis of the evolutionary rate of these excreted-secreted proteins. This study will contribute to our understanding of how pathogen recognition and defense mechanisms evolve and provide insight on proteins that could be key players in host-pathogen interactions.

W4180C Investigating the function of intestinal cell-cell communication in peptide secretion. *Lisa Learman*[1], Amy Vashlishan Murray[2], Maureen Peters[1]. 1) Dept. of Biology, Oberlin College, Oberlin OH; 2) Institute for Liberal Arts and Interdisciplinary Studies, Emerson College, Boston MA.

The *C. elegans* intestine acts as a neurosecretory organ, releasing small molecules that affect multiple aspects of physiology, including dauer formation, locomotion and defecation. Dauer formation is cued by intestinal release of IGF-1 in low food situations. When animals are feeding, the intestine undergoes periodic calcium waves that control the motor steps of the defecation cycle; these waves invoke secretion of signaling molecules that regulate defecation. This calcium spike appears to trigger the release of at least one peptide, NLP-40. Recent findings from the Biron lab suggest that an intestinally-derived signal induces a brief locomotory reversal in synch with the calcium wave. We believe that the intestinal calcium wave induces the release of factors affecting social feeding behavior, the tendency for worms to feed in large clumps rather than individually.

Altering intestinal cell-cell communication via mutation of a gap junctional subunit, INX-16, leads to an increase in social feeding. Worms with mutated *inx-16*, have slow, backward, or failed intestinal calcium waves known to affect defecation steps and the defecation associated locomotory reversals. *inx-16* mutants show a modest increase in social feeding (about 10% higher than N2). To determine whether the social feeding phenotype correlated broadly with defecation defects, we analyzed more defecation mutants: *pbo-4*, *pbo-5* and *aex-2*. None of these exhibited a significant social feeding phenotype suggesting that the social feeding in *inx-16* does not result from abnormal defecation in general.

To determine how *inx-16* mutation interacted with the known social feeding pathways we combined *inx-16* mutation with *npr-1* or *daf-7*. Addition of an *inx-16* mutation to a *daf-7* mutant significantly increased social feeding levels, which suggests that these two pathways are at least partly independent. The *npr-1*;*inx-16* double mutant produced a social feeding score similar to that of *npr-1* alone. This suggests that NPR-1 acts in the same pathway as INX-16 to mediate social feeding. NPR-1 can be activated by the neuropeptide FLP-21, which is reportedly expressed in the intestine. We hypothesize that, in *inx-16* mutants, abnormal intestinal calcium waves lead to defective FLP-21 secretion from the intestine and insufficient activation of NPR-1. Deletion of *flp-21* results in enhanced social feeding similar to that of *inx-16* mutation. Double mutants of *inx-16* and *flp-21* do not result in an additive increase in social feeding compared to single mutants. The intestinal calcium wave, itself dependent on feeding, appears to regulate the release FLP-21, thus modulating feeding behavior.

W4181A Understanding the secretion mechanism of VAPB/ALS8 MSP. *H. Zein-Sabatto*, M. Miller. University of Alabama at Birmingham, Birmingham, AL.

Most eukaryotic, secreted proteins travel through the conventional Golgi-ER secretory pathway. However, some proteins are unconventionally secreted independent of this route. We have shown that the major sperm protein (MSP) domain of VAPB/ALS8 is cleaved from the rest of the protein and secreted. MSP can be detected in human blood and cerebrospinal fluid (CSF), and its levels correlate with amyotrophic lateral sclerosis (ALS) pathogenesis. The goal of this project is to understand how VAPB MSP is proteolytically processed, secreted, and regulated. VAPB is a ubiquitously expressed type II membrane protein found anchored into the endoplasmic reticulum with the N-terminal MSP domain extending into the cytosol. The secreted MSP domain does not harbor a signal peptide characteristic of conventionally secreted proteins. *C. elegans* null mutants for *vpr-1*, the *Vapb* homolog, are sterile and have striated muscle mitochondrial abnormalities. Results from our lab provide evidence that the nervous system, germ line, and intestine are cellular sites of VPR-1 MSP secretion. Based on studies of *C. elegans* sperm MSPs, we hypothesize that VAPB MSP is secreted in a regulated fashion via an unconventional mechanism. In order to test our hypothesis, we developed an RNAi screening method using transgenic *C. elegans* to identify genes required for MSP secretion. *vpr-1(tm1411)* null mutants expressing VPR-1 only in the intestine (*pGES-1::vpr-1*) are fertile and can be grown as transgenic homozygotes, presumably because the MSP is secreted into the pseudocoelom. We predicted that RNAi of genes essential for VPR-1 MSP secretion would cause sterility. Using expression data, I have selected a set of 420 genes for a pilot RNAi screen. I have currently screened 210 RNAi clones and identified

10 candidate clones that cause severely reduced fertility in transgenic *vpr-1* mutants, but not in wild-type worms. Genome-editing techniques will be used to further characterize the role of selected candidates. I am also conducting a structure/function analysis to identify regulatory regions within VPR-1 necessary for MSP secretion. Finally, we have been characterizing multiple mouse *Vapb* mutants with skeletal muscle mitochondrial defects, in collaboration with Jin Chen's lab at Vanderbilt. I plan to use western blots of isolated mouse tissues to help define the mammalian cell types that proteolytically process VAPB to liberate MSP. VAPB MSP injections or drugs that improve VAPB MSP secretion could be therapeutic for ALS patients.

W4182B Identification of Conserved MEL-28/ELYS Domains with Essential Roles in Nuclear Assembly and Chromosome Segregation. *P. Askjaer*[1], G. Gómez-Saldivar[1], A. Fernandez[2,3], D. Ritler[4], Y. Hirano[5], A. Lai[2], M. Mauro[2], C. Ayuso[1], T. Haraguchi[5], Y. Hiraoka[5], F. Piano[3], P. Meister[4]. 1) CSIC-Univ. Pablo de Olavide, Seville, ES; 2) Fairfield Univ., Fairfield, CT, US; 3) NYU, New York, NY, US; 4) Univ. of Bern, Bern, CH; 5) Osaka Univ., Suita, JP.

Nucleoporins are the constituents of nuclear pore complexes (NPCs) and are essential regulators of nucleocytoplasmic transport, gene expression and genome stability. The nucleoporin MEL-28/ELYS plays a critical role in post-mitotic NPC reassembly through recruitment of the NUP107-160 subcomplex and is required for correct segregation of mitotic chromosomes. MEL-28 has a dynamic behavior: it localizes to nuclear pore complexes and chromatin during interphase and shuttles to kinetochores during cell division. However, it is unknown how MEL-28 localization and activity is regulated.

Here we present a systematic functional and structural analysis of MEL-28 in *C. elegans* early development and human ELYS in cultured cells. We have identified functional domains responsible for NPC and kinetochore localization, chromatin binding, mitotic spindle matrix association and chromosome segregation. Surprisingly, we found that perturbations to MEL-28's conserved AT-hook domain do not affect MEL-28 localization although they disrupt MEL-28 function and delay cell cycle progression in a DNA damage checkpoint-dependent manner. Our analyses also uncover a novel meiotic role of MEL-28. Together, these results show that MEL-28 has conserved structural domains that are essential for its fundamental roles in NPC assembly and chromosome segregation during meiosis and mitosis.

To understand the function of MEL-28 chromatin binding we have used DamID to identify the chromatin regions with which MEL-28 associates. Interestingly, MEL-28 is enriched at transcribed genes and correlates positively with active histone marks, suggesting that it may be involved in regulation of gene expression. We compared the MEL-28 chromatin profile with the profile of another nucleoporin, NPP-22, which is permanently anchored to the nuclear pore complex. Surprisingly, we found that the chromatin association profile of NPP-22 was more similar to the profile of the nuclear lamina protein LMN-1 than to MEL-28's profile, suggesting that individual NPPs interact with specific chromatin domains. Finally, GO-term analysis reveals that MEL-28-associated genes are related to larval and reproductive development. This suggests that MEL-28 has postembryonic functions that have not yet been studied.

W4183C LIN-10 promotes LET-23 EGFR signalling independently of LIN-2 and LIN-7. *K. Gauthier*[1,2], O. Skorobogata[1,2], C. Rocheleau[1,2]. 1) McGill Univ., Montreal, QC, CA; 2) The Research Institute of the MUHC, Montreal, QC, CA.

The spatial organization of signal transduction cascades is critical for regulating cell signalling and function. This is particularly evident in the polarized epithelia of *Caenorhabditis elegans* vulva precursor cells (VPCs) that give rise to the hermaphrodite vulva. Epidermal Growth Factor Receptor (LET-23 EGFR) signalling from the basolateral membrane is required for vulva cell fate induction. Basolateral localization of LET-23 EGFR is dependent on a ternary complex composed of LIN-2 CASK, LIN-7 Veli, and LIN-10 Mint1. Disruption of this complex results in exclusive apical mislocalization of LET-23 and a vulvaless (Vul) phenotype. This complex has been well-defined biochemically, however the cellular mechanisms by which it regulates LET-23 localization are not understood. We previously identified a pathway consisting of ARF GTPases, AGEF-1 (a putative Arf guanine exchange factor), and the AP-1 clathrin adaptor complex that antagonizes basolateral localization of LET-23 and negatively regulates signalling. Interestingly, mammalian LIN-10 homologue Mint1 binds Arf GTPases and may serve as an adaptor protein analogous to the AP-1 complex. My primary research objective is to discover how the LIN-2/7/10 complex functions with the AGEF-1/ARF/AP-1 ensemble to regulate LET-23 trafficking and signalling in the *C. elegans* VPCs. I found that GFP::LIN-10 localizes to cytoplasmic foci in the VPCs, which may represent Golgi mini-stacks or recycling endosomes. This localization is independent of LIN-2, LIN-7, and ARF GTPases, and is mediated by the C-terminal PTB and PDZ domains of LIN-10 that also mediate Arf binding in mammalian Mint1. Unexpectedly, I found that overexpression of LIN-10 rescues the *lin-2(e1309)* and *lin-7(e1413)* Vul phenotypes, indicating that LIN-10 promotes signalling independently of its complex. This effect is mediated by the C-terminal domains of LIN-10, and is LET-23 dependent. Going forward, I will test the hypothesis that LIN-10 promotes the EGFR signalling pathway by interacting with ARF. I will find if LIN-10 and ARF colocalize and interact in *C. elegans*, and I will test if this interaction is necessary and sufficient for the rescue of the *lin-2(e1309)* and *lin-7(e1413)* Vul phenotypes. Also, I will test if overexpression of LIN-10 can affect the subcellular localization of LET-23::GFP in the VPCs. This will be crucial towards understanding how LIN-10 overexpression is able to rescue the *lin-2(e1309)* and *lin-7(e1413)* Vul phenotypes. The results will offer new insight into how trafficking and scaffolding components work together to carefully regulate cellular events by controlling the spatial organization of signalling proteins in polarized cells.

W4184A Miro and dynein localize mitochondria in the intestine. *T. Inoue*, H. L. Chua, H. Y. Cheng, Y. Shen. National University of Singapore, Singapore, SG.

We are studying the role of Miro, an atypical small GTPase, in localization of intestinal mitochondria. In the wild-type, intestinal mitochondria are enriched near the apical surface of intestinal cells. We found that a mutation in *miro-1* disrupts this localization such that the distribution is more even across the intestinal cell. Using RNAi, we also found that components of the dynein motor protein are involved in this localization. We are carrying out additional experiments to identify other regulators of intestinal mitochondrial localization.

W4185B The liprin protein SYD-2 regulates synaptic vesicle localization in *C. elegans*. *X. Li*, JZ Qin, M. Ding. Chinese Academy of Sciences, Beijing, CN.

Chemical synapses are specialized structures to mediate communication between neurons and their target cells through neurotransmitter release mechanism. The transport, docking and release of neurotransmitters heavily rely on synaptic vesicles. Therefore the control of synaptic vesicle transport and localization is of great importance in the function, development and maintenance of nervous system. Here, we report that the *C. elegans* liprin protein SYD-2 is required for synaptic vesicle transport and localization. Mutations on *syd-2* lead to ectopic synaptic vesicle distribution, especially to the distal axon. *syd-2* regulated synaptic vesicle localization is dependent on kinesin/UNC-104. Previous study showed SYD-2 can physically interact with UNC-104, and UNC-104::GFP retrograde transport is increased in *syd-2* mutants. However, systematic genetic analysis implies that SYD-2 may recruit synaptic vesicles,which is independent from UNC-104-interaction. Overall, our study reveals an important role of active zone protein SYD-2 in synaptic vesicle localization.

W4186C *In vivo* function of the Kinesin-3 motor, KLP-4. *J. Pieczynski*, M. Magaletta. Rollins College, Winter Park, FL.

Proper neuronal function requires a dynamic microtubule network and the directed movement of ATP dependent, cargo binding motor proteins: the mostly plus-end directed kinesins and minus end directed dyneins. The efficient coordination of both microtubules and motors is required for proper structure-function paradigms of neuronal signaling, the establishment of proper morphology during development and then the movement of vesicular cargo to facilitate proper synapse formation and subsequent signal transduction. Failure of neurons to perform any of these functions can lead to multitudes of disease pathologies, including those characterized as cognitive, degenerative, psychiatric, and developmental. The Kinesin-3 superfamily, consisting of *C. elegans* UNC-104, KLP-6, and KLP-4, are all neuronally expressed motor proteins that are evolutionarily conserved between worms and other higher eukaryotes. *In vitro* studies using mammalian homologues of these motors indicate that Kinesin-3 motors exhibit high affinity for microtubules and that these motors possess relatively long run lengths, thus are highly processive. This high degree of processivitiy has been hypothesized as an evolutionary adaptation for the movement of cargo over long distances, such as neuronal axons. Questions still remain as to the exact roles of these motor proteins *in vivo;* how they contribute to intracellular trafficking, protein stability, neuronal morphology, and signal transduction. To address these questions, we have begun a reverse genetic screen focusing on *klp-4*, the *C. elegans* homologue to human KIF13A and KIF13B. Using a combination of commercially available strains produced via large-scale mutagenesis and bioinformatics, we have identified a number potentially deleterious *klp-4* alleles predicted to severely effect motor function. We are specifically interested in how mutation in KLP-4 may effect the paired AVB interneurons, which contain axons that extend the length the ventral nerve cord and are involved in the animal's forward locomotive circuit and behaviors such as spontaneous reversals, social behavior, and the establishment of long term memory. We have determined that mutation in *klp-4* does not appear to effect the development and gross morphology of the AVB interneuron, however different *klp-4* mutant animals appear to have reduced response to nose touch suggesting role for KLP-4 in the establishment of proper distribution of subcellular components in neurons *in vivo*.

W4187A A Search for Novel Presynaptic Determinants of Dopamine Signaling in *C. elegans*. *O. M. Refai*[1], J. A. Hardaway[2], S. Robinson[3], C. L. Snarrenberg[2], S. L. Hardie[3], P. Freeman[3], R. D. Blakely[1]. 1) Florida Atlantic University, Jupiter, FL; 2) Graduate Neuroscience Program, Vanderbilt University, Nashville, TN; 3) Department of Pharmacology, Vanderbilt University, Nashville, TN.

The catecholamine dopamine (DA) is a catecholamine neurotransmitter found in both vertebrates and invertebrates, where it modulates a wide variety of behaviors including movement, attention and reward. In humans, disruption of DA levels and signaling are associated with multiple brain disorders, including Parkinson's disease, Schizophrenia, Attention Hyperactivity Disorder (ADHD) and addiction. In the nematode *C. elegans*, DA supports motor and sensory function, with excess DA transmission triggering Swimming-Induced Paralysis (Swip), a readily visible phenotype that we have shown to be well-suited to forward genetic efforts to identify DA regulatory genes. Here we describe our efforts to characterize two mutant lines, *vt39* and *vt44*, isolated in an EMS-based screen for animals exhibiting Swip. Similar to DA transporter (*dat-1)* mutants, the Swip exhibited by *vt39* and *vt44* is rescued by either treatment of animals with the vesicular monoamine transporter (*cat-1*) inhibitor reserpine or by crossing these lines to animals that lack expression of the D2-type DA receptor DOP-3. Direct genomic sequencing, and complementation tests, indicate that both lines harbor a normal *dat-1* gene. Using a single nucleotide polymorphism-based mapping approach, we find that *vt39* and *vt44* map to chromosomes I and III, respectively. Fine mapping and whole genome sequencing are underway to identify the genes mutated in these lines, efforts to be followed by genomic and cDNA rescue efforts to validate gene identification and to determine cell autonomy with respect to Swip induction. Supported by NIH Award MH095044 (R.D.B.) and MH093102 (J.A.H.).

W4188B A *C. elegans* model for Human Antigen R. *Zhe Yang*, Matthew Buechner. University of Kansas, Lawrence, KS.

Human antigen (Hu) proteins HuB, HuC, HuD, and HuR are a family of RNA-binding protein that stabilize mRNA by binding to AU-rich elements (ARE) in the 3'UTR. HuR is universally expressed in human cells, and stabilizes many tumor-related genes such as *bcl-2*. HuR is upregulated in many cancer cell types involved in breast and colon cancer. EXC-7 is the sole homologue of the Hu proteins in *C. elegans*. EXC-7 maintains the single-cell tubular canals of the excretory cell by stabilizing *sma-1* mRNA, encoding β_H-spectrin. Mutants in *exc-7* exhibit small fluid-filled cysts throughout shortened excretory canals, as well as a misshapen tailspike. Both EXC-7 and HuR contain 3 RNA-recognition motifs (RRMs), with a region between the 2nd and 3rd RRM that appears to be needed for intracellular transport. We are investigating the functional equivalence of these proteins, by determining whether human HuR can functionally replace EXC-7 in *C. elegans*. If so, then *C. elegans* could be developed as a model for studying HuR *in vivo*, especially for screens for chemicals that interfere with HuR function, using excretory canal phenotype as a measure of HuR activity. I have injected the *hur* coding region driven by various promoters to express HuR within the excretory canals. HuR

cDNA appears to rescue partially both the length and diameter of the excretory canal lumen in *exc-7* mutants. Modification of the structure of the injected HuR gene showed better rescue effects. We will further modify the structure of HuR and seek solutions to fully rescue canal defects, and are making worm/human chimeric proteins to investigate domain activity of these proteins and study the binding partners, the mRNA targets of EXC-7.

W4189C A vesicle-intrinsically regulated pathway for apical polarity. *Nan Zhang*[1,2], Hongjie Zhang[1,3], Liakot Khan[1], Gholamali Jafari[1], Yong Eun[1], Edward Membreno[1], Razan El-Daouk[1], Verena Gobel[1]. 1) Mucosal Immunology and Biology Research Center, MGH/Harvard Medical School, Boston, MA, USA; 2) College of Life Sciences, Jilin University, Changchun, Jilin, China; 3) Faculty of Health Sciences/University of Macau, Taipa, Macau, China.

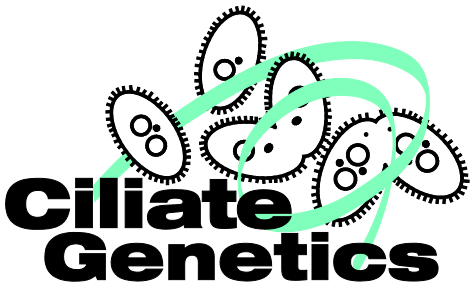
Polarized epithelial membrane domains are thought to be established by membrane- and junction-associated polarity cues (e.g. partitioning-defective PARs), with directional trafficking subsequently maintaining them. Our prior work showed that glycosphingolipids (GSLs), clathrin and its AP-1 adaptor function as vesicle-associated apical polarity cues in *C. elegans* tubular epithelia. Their loss causes intestinal polarity inversion with a full basolateral-to-apical membrane domain conversion and ectopic lateral lumen formation. These and other findings suggested that trafficking itself may define polarized domain identities, in part by targeting polarity determinants (e.g. PARs), but possibly by targeting multiple membrane components.

Here, the GSL-loss-of-function intestinal polarity inversion phenotype was used to identify components and map trajectories of such a putative vesicle-intrinsically regulated apical polarity pathway. We mined three of our unbiased and targeted multi- and unicellular tubulogenesis screens that had examined the asymmetrical placement and function of the apical/lumenal actin linker ERM-1 for genes with predicted roles in trafficking. 49 trafficking genes with a broad range of vesicle-associated functions were identified as required for apical membrane biogenesis, only few of which previously implicated in directional trafficking. We examined the ability of these genes to modify polarity inversion in the GSL-biosynthetic 3-ketoacyl-CoA reductase deficient mutant *let-767*.

These genetic interaction screens identified eleven enhancers implicating secretory/biosynthetic trafficking routes in this pathway, and five suppressors implicating endocytic/recycling routes. In an attempt to map polarized trajectories, three suppressors, DAB-1/Disabled, RAB-7, and VHA-6 (a V-ATPase component), were selected for further analysis. Imaging and loss-of-function studies of expanding intestines revealed unexpected functions in apical and basolateral membrane biogenesis for these endo- and plasma-membrane-associated molecules and placed them on recycling routes. They thereby position suppressors upstream of GSL sorting sites, while in turn suggesting that GSLs may sort beyond the Golgi on biosynthetic trajectories that receive input from recycling routes during plasma membrane biogenesis.

This study identifies multiple vesicle components for polarized trafficking, including novel vesicle-carrier-associated polarity cues, and proposes trajectories for a vesicle-intrinsically regulated trafficking pathway for apical polarity.

2016 CILIATE MOLECULAR BIOLOGY MEETING



Poster Session Abstracts

CILIATES POSTER SESSION ABSTRACTS

C7001A Evolution of gene families in ciliates. *O. A. Pilling*[1], X. X. Maurer-Alcalá[1,2], L. A. Katz[1,2]. 1) Smith College, Northampton, MA; 2) University of Massachusetts Amherst, Amherst, MA.

We use ciliates as a model to gain insight into how genome structure affects patterns of DNA sequence evolution. Previous research has demonstrated that ciliates, a clade of eukaryotes marked by dimorphic nuclei and cilia in at least one stage of their life cycle, have rapid rates of protein evolution associated with highly processed somatic genomes (Katz et al. 2003; Zufall et al. 2006). We are building on this work by investigating the protein evolution of three species of ciliates in the class Heterotrichea, which has previously been understudied. Our focus is on characterizing patterns of divergenes among paralogs (i.e. genes that differ due to an ancient duplication events). For this project, we focus on the ciliates *Blepharisma americanum*, *Stentor sp.* and *Spirostomum ambiguum*, and six genes (Actin, α-tubulin, β-tubulin, Ef1-α, H3 and H4).

We chose to study *B. americanum* because preliminary data suggest they may have elevated rates of protein evolution (Zufall et al. 2006). Unlike the classes Spirotrichea, Armophorea and Phyllopharyngea where rates of protein evolution are associated with extensively processed somatic genomes (e.g. 'gene-sized' chromosomes), members of the Heterotrichea are not known to extensively modify their macronuclear genomes. We are using PCR based approach to analyze protein evolution and are interpreting the resulting data in a molecular evolution framework.

This project has included both wet work and bioinformatics. While the majority of the wet work is completed, we are now beginning to analyze the data by calculating the dN/dS ratio and performing pairwise comparisons. Through this approach, we can start to better understand the impact genome architecture has on molecular evolution.

C7002B Mapping and characterization of DNA replication origins in *Tetrahymena thermophila*. *L. Zhang*, M. Cervantes, G. Kapler. Texas A&M Health Science Center, College Station, TX.

Origins of replication act as sites for the initiation of DNA replication via recruitment of ORC (Origin Recognition Complex). ORC mediates loading of the MCM2-7 helicase to 'license' replication competence. Although ORC is conserved in eukaryotes, the mechanism for origin recognition is not. *S. cerevisiae* ORC binds to a conserved sequence motif present at all origins. *S. pombe* and metazoan ORCs binds non-specifically to AT-rich DNA. Genome-wide studies have uncovered several general features of origins.

We are developing a high throughput DNA sequencing approach to obtain a comprehensive map of replication initiation sites in *Tetrahymena thermophila*. This approach will provide the first comprehensive picture of origin usage in the early diverging Ciliophora lineage and reveal genomic features of replication origins. As part of this project, we have developed a functional assay to validate replication origins. Our data indicate that specific intergenic DNA sequences are required to support DNA replication of episomal plasmids as autonomously replicating sequences (ARSs). ARS assays are being used to map origins and uncover DNA sequences requirements. To identify new origins, nine non-coding segments from a small non-rDNA macronuclear chromosome were introduced into an origin-less vector that confers resistance to paromomycin. These plasmids were introduced into vegetative Tetrahymena by biolistic transformation as a pool. A plasmid containing the well-characterized rDNA origin served as positive control, and an empty vector served as negative control. The non-rDNA pool generated >100 folds more transformants compared to negative controls. After cultured for >100 generations, episomal DNA was recovered by Qiagen columns and re-transformed into *E. coli*. Massive DNA rearrangements were detected in *E. coli* clones. This was not unexpected, as AT-rich Tetrahymena sequence frequently rearrange in *E.coli*. Thus far we have recovered sequences from one 0.8 kb Tetrahymena insert, suggesting that this fragment supports DNA replication in Tetrahymena. We are currently use direct sequencing to identify Tetrahymena origin sequences. As further confirmation, endogenous chromosomal loci are being examined by 2D gel electrophoresis.

Our lab recently discovered an unconventional DNA replication program in Tetrahymena that operates when ORC proteins are dramatically depleted. Known origins are silenced and cryptic origins are activated. This suggests the presence of cryptic origins whose chromosomal replication initiation signal is too weak to be detected in population-based assays. We plan to exploit ARS assays to identify replication determinants under high and low ORC conditions.

C7003C Investigations into the Paramecium iesRNA pathway. *S. Allen*, E. Swart, M. Nowacki. University of Bern, Bern, CH.

The iesRNA pathway is a small RNA pathway involved in the excision of internal eliminated sequences (IESs) during Paramecium development. iesRNAs appear late in development, after IES excision (both scnRNA dependent and independent) has been initiated. Evidence suggests that iesRNAs are formed directly from excised IESs, but the mechanism for this putative transcription is not clear. Many iesRNA-affected IESs are only 27 bp long, and iesRNAs bind perfectly to the ends of the IESs. The transcription of a Dicer cleavage substrate from such a short DNA template seems unlikely.

We wish to investigate the iesRNA pathway in more detail, via a number of approaches. We are examining the robustness of iesRNA-guided IES excision via the introduction of artificial iesRNAs, and by inducing the removal of both endogenous and cryptic IESs via the introduction of IES-like dsDNAs. Of particular interest are iesRNA precursors, the identity of which has proven elusive. We investigate the possibility of IES concatamer formation, which would provide a mechanistic explanation for the formation of iesRNAs from excised IESs.

CILIATES POSTER SESSION ABSTRACTS

C7004A Multiple Layers of Nested Genes in the Complex Genome of *O. trifallax*. *J. Braun*, N. Jonoska, M. Saito. Univ. of South Florida, Tampa, FL.

Massive genome rearrangement processes are known to occur during the sexual reproduction of the ciliate *Oxytricha trifallax* making it an ideal model organism to study gene rearrangements. During these processes a transcriptionally active somatic nucleus (macronucleus) is developed from a copy of its germline nucleus (micronucleus). In the micronucleus, macronuclear genes are found divided into potentially scrambled and inverted segments. Some regions between consecutive macronuclear destined segments of one gene contain multiple layers of segments from other genes. This nesting of gene segments significantly contributes to the complexity of the DNA recombination. Mathematical notions to measure the nesting of gene segments have been developed. Through computational analysis, we have identified all occurrences of interleaving segments and 137 instances of 2 to 4 levels of nested genes have been detected in the recently sequenced genome of *O. trifallax*.

C7005B Environmental temperature and its impact on the process of programmed DNA elimination in *Paramecium*. *F. Catania*, G. Churakov. Institute for Evolution and Biodiversity, Muenster, DE.

In ciliates the process of programmed DNA elimination is crucial for the formation of viable sexual offspring. The elimination of thousands of Internal Eliminated Sequences (IESs) from the germline genome occurs at each sexual event and enables the regeneration of a functional somatic nucleus.

Given how critical it is, one may expect that IES excision is virtually insusceptible to mild environmental stress. The impacts of environmental conditions on the accuracy of IES elimination remain an open question, however. We attempted to address this question by exposing self-fertilizing clonal *Paramecium* lines to different environmental temperatures and then by screening these lines' somatic genome for IES retention. Our observations provide insights on the extent to which the fidelity of genome rearrangements in *Paramecium* varies in response to environmental changes.

C7006C Complex Rearrangements in the Highly Scrambled Genome of O. trifallax. *Lukas Nabergall*, Natasha Jonoska, Masahico Saito. Univ. of South Florida, Tampa, FL.

Certain species of ciliates undergo massive genome rearrangements during the development of a somatic macronucleus from a germline micronucleus, and are used as model organisms to study DNA rearrangement. Recent sequencing of the *O. trifallax* germline genome allows for the detailed study of scrambled patterns genome-wide. We present a mathematical framework to describe the order and orientation of scrambled segments (the macronuclear-destined sequences, or MDSs). For example, we catalog all germline loci with odd/even patterns that partition MDSs (an example would be 1-3-4-2-4-6, etc.) and many elaborate variations. We have observed that occurrences of such patterns can explain approximately 82% of all scrambled loci. We also study the complexity of the remaining highly scrambled cases, some of which contain nested occurrences of such patterns.

C7007A Identification and Characterization of the SIRT4/5 Homologs in *Tetrahymena thermophila*. *Emily Nischwitz*, Joshua Trammell, Joshua Smith. Missouri State University, Springfield, MO.

Tetrahymena thermophila contains 18 putative histone deacetylases (HDACs) homologs. Eleven of these homologs are in the Sirtuins subfamily (NAD-dependent Histone Deacetylases). Sirtuins plays a key role in many functions in the cell such as cellular metabolism, removing acetyl groups on histones as well as other proteins in the cell, and have been show to have a role in cancer, neurodegeneration and cardiovascular disease. The scope of this research is to study the localization and expression levels of Tetrahymena Histone Deacetylases 10, 17, and 18 (*THD10, THD17,* and *THD18*), which are homologs of SIRT4 and SIRT5 in humans. To characterize these genes bioinformatic analysis was conducted and then PCR was performed to amplify the gene. The gene product was cloned into the pENTR-TOPO-D plasmid, transformed into E. coli, and ultimately to study the localization tagged with GFP and other epitope tags to study the function within the cell. The expression of these genes has been analyzed under various damaging agents at various time points through qRT-PCR. The damaging agents used in these studies are hydrogen peroxide, methyl methanesulfonate, ultraviolet light that creates distinctive DNA damage and DNA repair responses. This research will better elucidate if there is a possible function of the Tetrahymena SIRT4 and SIRT5-like homologs (*THD10, THD17*, and *THD18*) within DNA damage repair by studying both the localization and expression levels under different conditions.

C7008B A nuclear RNAi-dependent *Polycomb* repression pathway is required for transcriptional silencing of transposable elements. *L. Feng*[1], J. Xiong[1,2], S. Gao[1,3], W. Dui[1], W. Yang[2], A. Kapusta[4], C. Feschotte[4], R. Coyne[5], W. Miao[2], Y. Liu[1]. 1) University of Michigan, Ann Arbor, MI; 2) Institute of Hydrobiology, Chinese Academy of Sciences, Wuhan, China; 3) Ocean University of China, Qingdao , China; 4) the University of Utah School of Medicine, Salt Lake City, UT; 5) J. Craig Venter Institute, Rockville, MD.

Studies of developmentally regulated heterochromatin formation and DNA elimination in the unicellular eukaryote *Tetrahymena thermophila* have revealed a pathway requiring both nuclear RNA interference (RNAi) and PcG proteins, providing a unique opportunity to dissect the interaction between them. Internal eliminated sequences (IES) in *Tetrahymena* are derived from transposable elements (TE). A wide array of potential TE are revealed in the recently sequenced *Tetrahymena* MIC genome. Recent transposition in *Tetrahymena* population is supported by TE insertion polymorphism in IES, as well as purifying selection in coding sequences of many potential TE. Nonetheless, the molecular mechanism underlying transcriptional silencing and reactivation of TE remains elusive.

RNAi and *Polycomb* repression play evolutionarily conserved and often coordinated roles in transcriptional silencing. Here we show transcription reactivation of IES in mutants deficient in nuclear RNAi and *Polycomb* repression. Importantly, transcriptional silencing and reactivation of TE-related sequences are contingent upon shunting between the noncoding RNA (ncRNA) and mRNA production pathways,

which can be affected by co-transcriptional processing, nuclear RNAi, and *Polycomb* repression. We propose that interplay between the nuclear RNAi and *Polycomb* repression pathways may be a widespread phenomenon, whose ancestral role is epigenetic silencing of TE.

C7009C Regulation of *Tetrahymena* germline transcription in meiotic prophase by three novel proteins. *M. Tian*[1], K. Woolcock[2], K. Mochizuki[2], J. Loidl[1]. 1) Max F. Perutz Laboratories, Vienna, AT; 2) Institute of Molecular Biotechnology of the Austrian Academy of Sciences, Vienna, AT.

Nuclear dimorphism is a characteristic feature of the ciliated protists. The macronucleus (MAC) is transcriptionally active during vegetative growth, whereas the germline micronucleus (MIC) is completely transcriptionally silent during vegetative growth. However, the active transcription of the MIC genome is essential for sexual reproduction.

During the sexual reproduction of ciliated protist *Tetrahymena*, its MIC undergoes meiosis, at the same time, the RNA polymerase II (RNAPII) is recruited to the MIC, and then double stranded non-coding RNAs are generated by bi-directional transcription of the germline genome. The double stranded non-coding RNAs are further processed into small RNAs (called scnRNAs) by Dicer homolog Dcl1, and are guiding the deletion of one-third of the genome from the developing progeny MAC. Although the molecular mechanisms underlying the small RNA-directed DNA elimination event during the sexual process of conjugation have been intensively studied, the activation and regulation of germline transcription is still a mystery. By deleting genes that are specifically expressed in meiotic prophase of *Tetrahymena*, we have identified three (*RIB1, MIP1, MIP2*) genes that are involved in regulation of germline transcription. Knockout of any of them blocks the accumulation of non-coding RNAs from the germline nucleus and prevents the DNA elimination process, indicating that these three genes are essential for germline transcription. Rib1 and Mip1 proteins are specifically localized in the MIC during meiosis. Interestingly, the localization of Rib1 is similar to that of the RNAPII specific subunit Rpb3 in the meiotic prophase MIC. However, the localization of Rpb3 is not affected by the deletion of *RIB1*, indicating that Rib1 might be critical for activating RNAPII transcription but not required for the localization of RNAPII. The deletion of *MIP1* disrupted the localization of Rib1 and Rpb3 to chromatin, suggesting that Mip1 plays a role in the recruitment of RNAPII and possibly its auxiliary factors, such as Rib1, to the MIC. Also in a *mip2* deletion, Rib1 and Rpb3 are mislocalized. Therefore, the Mip2 protein is possibly required for micronuclear import of Rib1 and the proper distribution of RNAPII within the MIC.

Finally, we noticed that the knockout of *MIP1* and *MIP2* lead to the extension of meiotic prophase, which might suggest delayed repair of meiotic DNA double-strand breaks in *mip1*Δ and *mip2*Δ cells.

C7010A Cas9 localization in the binucleated ciliate *Tetrahymena thermophila*. *K. Fryer*, D. Cassidy-Hanley, D. Kolbin, T. Clark. Cornell University, Ithaca, NY.

CRISPR-Cas9 is quickly becoming a standard genome editing tool and has been used in various model organisms. It has yet to be implemented or optimized for use in *Tetrahymena* or ciliates in general despite the implications it has in facilitating germline modifications in binucleate systems. Cas9 has been shown to localize to the nucleus and gain access to DNA in other organisms without any nuclear localization sequence modifications. While this is standard in most systems, the presence of both a transcriptionally active macronucleus and a transcriptionally silent, germinal micronucleus, which has very different membrane characteristics, presents a unique question for ciliates: is Cas9 targeted to one or both nuclei? To answer this question we transformed *Tetrahymena thermophila* with an expression cassette, provided by Dr. Douglas Chalker and Dr. Robert Coyne, containing Cas9 fused to a micronucleus specific linker histone (MLH) and YFP under the inducible MTT1 promoter. We looked at Cas9 expression in induced transgenic cells during vegetative growth, starvation, early conjugation, and late conjugation. No observable signal was seen in the micronucleus or the macronucleus using either YFP fluorescence or anti-Cas9 antibody immunofluorescence, although some punctate staining was observed in the cytoplasm. Western blots of total cell protein extracted from induced cells probed with anti-Cas9 antibodies also showed no detectable signal corresponding to Cas9. Based on these observations, we hypothesized that the very large fusion protein containing Cas9, MLH, and YFP might be unstable or unable to enter the nuclei and may be rapidly degraded by the cell. To test this hypothesis we constructed two vectors, one containing just Cas9 fused only to YFP and one containing just Cas9. Using these smaller constructs, we intend to determine if Cas9 successfully enters either the micronucleus or the macronucleus during vegetative growth or conjugation. This work will help to establish and optimize conditions for Cas9 localization in *Tetrahymena*, and is an important first step in implementing CRISPR technology in this system.

C7011B Epigenetic control of DNA replication revealed in *Tetrahymena thermophila* TXR1 knockout mutants. *Miguel F. Gonzales*[1], Chunxiao Ge[1], Xianzhou Meng[1], Yin Liu[2], Geoffrey M. Kapler[1]. 1) Texas A&M, College Station, TX; 2) University of Michigan, Ann Harbor, MI.

DNA replication initiates at specific sites in chromosomes termed Origins of Replication (ORI). In eukaryotes, these sites are chosen by the binding of the Origin Recognition Complex (ORC) and subsequent recruitment of the MCM2-7 helicase to generate the pre-replicative complex during the G1 phase of the cell cycle. The relative contributions of the DNA sequence (cis-acting determinants) and chromatin context (histone modifications) to ORI function vary widely in eukaryotes, and are the subject of considerable debate. Previous studies revealed a role for the monomethylation of histone H3 on the 27th lysine residue (H3K27) in the control of DNA replication in the polyploid macronucleus of the model eukaryote, *Tetrahymena thermophila* (Gao et al., Genes Dev. 2013). H3K27 monomethylation appears to be restricted to the ciliate lineage and plants, and is mediated in *Tetrahymena* by TXR1 - a homologue of *Arabidopsis thaliana* ATXR5/ATXR6. TXR1 contains a SET-domain enabling the monomethylation of H3K27, and harbors a PCNA-interacting-protein (PIP) box. Taken together, the features of TXR1 suggest a role in DNA replication and/or DNA damage repair.

Using 2D gel electrophoresis of DNA replication intermediates (RIs), we provide evidence for the role of TXR1 in replication initiation in the ribosomal DNA (rDNA) minichromosome. Aberrantly migrating RIs emanate from the rDNA 5' non-transcribed spacer (5' NTS), but not from the

rRNA coding region which is consistent with TXR1-dependent modification of intergenic histone H3 subunits. The novel properties of these RIs are unprecedented suggesting an unconventional nucleic-acid structure. To unveil the structure and nucleic acid content of aberrant RIs, we are employing different nuclease digestions and using the RNA-DNA hybrid-specific S9.6 monoclonal antibody to assess whether non-coding transcripts are involved. Finally, DNA fiber imaging of non-rDNA chromosomes revealed a global effect on replication initiation illustrated by the firing of fewer origins resulting in increased inter-origin distances in TXR1 knockout strains. The average rate for replication fork elongation in TXR1 mutants is indistinguishable from wild type; however, our data suggests that a subpopulation of forks either stall, collapse, or move slower in a TXR1 knockout background. We surmise two possibilities to explain the data: (1) TXR1-dependent modification of the *Tetrahymena* epigenome determines replication initiation sites, and (2) TXR1 is required to re-start stalled replication forks near origin initiation sites.

C7012C ***Gene expression in Paramecium as a response to DNA damage*****.** *R. Stewart*[1*], T. Doak[1,2], L. Bright[1], M. Lynch[1]. 1) Indiana University Bloomington, Bloomington, IN; 2) NCGAS, Bloomington, IN.

Many environmental assaults damage DNA—an organism's genetic identity—but mechanisms have evolved to repair this damage. Oxidative damage, induced by reactive oxygen species such as hydrogen peroxide, is an example of these assaults. The consequences of DNA damaging agents are directly related to the cell's ability to appropriately respond to and repair DNA damage (Sobol et al 2002), using pathways appropriate to each type of damage. But these processes can't be initiated without the expression of genes coding for the repair enzymes. These processes have yet to be fully studied for ciliated protozoa, single-celled eukaryotes, but a few studies exist for *Tetrahymena thermophila*, using several damage mechanisms. These studies have confirmed that a number of repair genes known from other model systems are also induced in ciliates (Smith et al 2004). But these studies have been limited to candidate genes—homologs to repair enzymes known in other systems. To look for additional genes and to provide complementary data sets, several species of the related ciliate *Paramecium*, including *Paramecium caudatum* and *Paramecium tetraurelia*, were examined for their responses to oxidative damage, using protocols published on the treatments of Tetrahymena. Paramecium were treated to .3% hydrogen peroxide (after verifying that the Tetrahymena dose was appropriate for Paramecium) and RNA were collected after zero, one, two, three and four hours. The next stage is to turn these RNAs into next generation sequencing RNAseq libraries. After these libraries are sequenced at the IU Center for Genomics and Bioinformatics (CGG), I will examine the levels of mRNA transcripts produced for each gene after DNA damage, compared to its normal level of expression. Based on this comparison I should be able to determine which genes are expressed at higher levels after DNA damage. I expect to see a high level of mRNA transcripts for known repair genes, such as those known to be associated with DNA repair in Tetrahymena thermophila. However, it is also possible that I might discover genes that are not yet known to be associated with DNA repair, unique to ciliates.

C7013A Identification and Investigation of the Function of Rad23 in DNA Repair and Proteosomal Degradation in *Tetrahymena thermophila*. *Evan Wilson*, Joshua Smith. Missouri State University, Springfield, MO.

Rad23 is a protein involved in both nucleotide excision repair (NER) and proteasome-mediated degradation, and has been suggested to facilitate interactions between these two pathways. Until recently, Rad23-related research has been conducted using *Saccharomyces cerevisiae*. By instead using *Tetrahymena thermophila,* which has a transcriptionally silent micronucleus, the role of Rad23 in global genome NER (ggNER) can be better understood. The *T. thermophila* homolog for RAD23 was identified through bioinformatics analysis. Expression levels and ubiquitination of Rad23 before and after multiple genotoxic stressors was assessed using qRT-PCR and western blot analysis, respectively. Additionally, interacting partners of Rad23 in both the proteasome and the NER pathway will be analyzed using fluorescent co-localization and co-immunoprecipitation. Finally, survival assays of knockdown strains will be used to determine the roles of Rad23 and other interacting partners. An advantage of this research is that tagging and knockdown constructs will be created by using an endogenous tagging vector. Inserting a tagged gene into its natural locus under its own promoter prevents aberrant expression and phenotypes from an inducible promoter that can result from certain experimental conditions.

C7014B The investigation of *Caedibacter taeniospiralis* Reb-related genetic elements in paramecia using fluorescent and phylogentic methodologies. *David Johnson*. Samford University, Birmingham, AL.

The paramecium bacterial endosymbiont *Caedibacter taeniospiralis* produces a protein R-body with four Reb subunits. Recently, a homolog of the gene responsible for the RebB subunit has been discovered as a trichocyst gene in the nuclear genome of a cryptomonad. Here we present our progress on developing a novel *in situ* methodology for detection of the RebB gene and a preliminary phylogenetic analysis of cryptomonad trichocysts genes found in freshwater and marine water samples.

C7015C On the evolution of a family of cis-acting elements for programmed somatic chromosome fragmentation. *E. Orias*. UC Santa Barbara, Santa Barbara, CA.

Ciliates segregate germline and somatic function to two separate nuclei within a single cell. During the development of a new somatic nucleus in *Tetrahymena thermophila*, site-specific fragmentation of the 5 chromosomes derived from the germline (micronucleus or MIC) generates ~200 somatic (macronuclear or MAC) chromosomes. The 15-bp Cbs (Chromosome breakage sequence) family is the necessary and sufficient cis-acting DNA element for programmed chromosome fragmentation. Roughly half of the Cbs's in the MIC genome (109/225) have the consensus sequence, TAAACCAACCTCTTT, with T at each of the only 5 variable positions. No Cbs known to be functional contains substitutions at >2 variable positions. Only at variable positions 1 & 11 have the nucleotide frequencies achieved the maximum diversity expected if all isoforms are functionally equivalent. *Cbs-mediated* chromosome breakage is limited to Tetrahymenine ciliates, raising the possibility that not enough evolutionary time has elapsed to achieve maximal diversity at Cbs positions 13-15.

The letter preceding the number is the community. A, B, C after the number is presentation time.
W – *C. elegans*, C – Ciliates, D – Drosophila, M – Mouse, P – PEQG, Y – Yeast, Z – Zebrafish

To better understand how the current *T. thermophila* Cbs family evolved, a computer simulation has been undertaken. Random mutations at natural rates are allowed in DNA segments that contain the 15-bp Cbs, while 15-bp segments of unconstrained sequence flanking the Cbs on either side act as controls. Simulation results include the following:

1) Simulations starting with the current Cbs complement have reproduced the finding, by calculation, that diversity is currently maximal at positions 1 & 11, but not at positions 13-15.

2) In simulations starting with an all-consensus full Cbs complement, the consensus Cbs frequency decreases from 100% to its current value (~50%) well before maximal diversity is approached at positions 1 & 11 – seemingly inconsistent with the maximum diversity currently observed as these 2 positions.

3) A and T are the only nucleotides allowed at positions 1 & 15. The observed asymmetry in the A:T frequency ratio at positions 1 (32% A) and 15 (9% A) is not reproduced by these simulations, which generate equal relative frequencies at both positions.

The results are informative, as they suggest refinement of particular null assumptions made in the initial simulations. Additional results and hypotheses will be discussed. Sequencing additional Tetrahymenine germline genomes should generate valuable relevant data and additional evolutionary insights.

C7016A Hemp seed extract enhances excystation and survival across genetically diverse ciliates. *S. Phadke*. J Craig Venter Institute, La Jolla, CA.

Starvation triggers various morphological and physiological responses in ciliates. One of the common responses is the formation of dormant structures such as cysts, which have highly reduced metabolic activity that allows survival of the individuals until optimum environmental conditions return. Dormancy represents an adaptive strategy for the ciliates and is also ecologically important for maintenance of microbial diversity. We investigated the diversity of cyst forming ciliates in 42 dried soil samples collected across the continental United States. Together, the samples represent 11 soil types and 5 climate zones. The soils were hydrated with or without hemp seed extract and ~10-50 single cells representing various ciliate morphospecies were isolated from each sample at ~48 hours after hydration. We analyzed the species diversity using 18s rRNA sequences of the isolates and found significant differences in species composition across the samples collected in different soil types. Also, hydration in the presence of hemp seed extract allowed excystation of a higher diversity of species and also allowed longer survival of the ciliates. It is unclear if addition of hemp seed extract simply provided higher nutrients allowing denser growth of bacteria that in turn supported the higher diversity of ciliates. Alternatively, hemp seed extract may directly provide complex nutrients required for excystation of certain ciliate species without significantly affecting bacterial growth. Our results emphasize the need to investigate how nutrient sensing pathways have diversified across cyst-forming ciliates.

C7017B Phylogenetic framework of the systematically confused *Anteholosticha-Holosticha* complex (Ciliophora, Hypotricha) based on multigene analysis. *X. Zhao*[1,2], S. Gao[2], Y. Fan[2], M. Strueder-Kypke[3], J. Huang[1,2]. 1) Key Laboratory of Aquatic Biodiversity and Conservation of Chinese Academy of Sciences, Institute of Hydrobiology, Chinese Academy of Sciences, Wuhan 430072, China; 2) Laboratory of Protozoology, Institute of Evolution and Marine Biodiversity, Ocean University of China, Qingdao 266003, China; 3) Department of Zoology, University of Guelph, Guelph, Ontario, N1G 2W1, Canada.

The *Anteholosticha–Holosticha* complex is an extremely divergent group within the urostylids, especially because the genus characterization lacks suitable synapomorphies. Previous studies have shown that morphological classification of species within this group often conflicts with SSU-rDNA data, that is this complex is not recovered as a monophyletic group and *Anteholosticha* spp. are widely dispersed throughout the urostylid assemblage in SSU-rDNA trees. In this study, we provided 38 new sequences (including the type species of *Anteholosticha*) of SSU-rDNA, ITS1-5.8S-ITS2 and LSU-rDNA genes to infer molecular phylogenies of all available taxa in the *Anteholosticha–Holosticha* complex. The results show that: (1) *Holosticha* is monophyletic in all trees, suggesting it is a well-defined genus; (2) *Anteholosticha* is polyphyletic and distinctly separated from *Holosticha* in all single-gene based and concatenated phylogenies; (3) the monophyly of *Arcuseries*, a recently established genus split from *Anteholosticha*, is strongly supported by all molecular data; (4) *Anteholosticha multicirrata*, *Anteholosticha manca*, *Anteholosticha paramanca* and *Bakuella subtropica* may share a most recent common ancestor; (5) multi-gene analyses receive higher support values than the single-gene analyses.

C7018C Genetic analysis of the molecular properties underlying centriole stability. *N. E. DeVaul*, K. F. O'Connell. National Institutes of Health , Bethesda, MD.

Centrioles are barrel shaped organelles that play a central role in microtubule organization; in dividing cells, centrioles direct the formation of the mitotic spindle, and in differentiated cells, centrioles organize the formation of cilia and flagella. Centrioles typically exist in pairs, and to properly execute centriole-dependent processes, cells must possess one or two pairs of centrioles. Three properties of centrioles contribute to the strict copy number control: a precise duplication event that occurs once per cell cycle, equal partitioning of centriole pairs to daughter cells at division, and the long–term stability of centrioles once formed. While much is known about centriole duplication and segregation, relatively little is understood about the molecular basis of centriole stability. Five highly conserved factors required for centriole assembly have been identified in the nematode *C. elegans*. This includes SAS-6, a coiled-coil containing protein that forms a central scaffold for centriole assembly. Down regulation of any of the centriole assembly factors blocks formation of new centrioles but does not affect existing centrioles. We have recently identified a new mutant allele of the *sas-6* gene that contains a missense mutation (D9V) affecting the globular N-terminal domain. This domain directs the formation of higher order oligomers of SAS-6 and the assembly of a centriole scaffold. Animals homozygous for this mutation exhibit an embryonic lethal phenotype marked by the presence of monopolar spindles, a phenotype consistent

with a defect in centriole assembly. However, these mutants also exhibit an additional unexpected phenotype. In the male germ line of such mutants, centrioles duplicate normally during the early stages of spermatogenesis but appear to disassemble following the meiotic divisions. As a result, sperm lack detectable levels of centriole proteins including SAS-6, SAS-4 and SPD-2. Thus in the male germ line, centrioles appear to duplicate normally but the long-term stability of these structures is compromised. Our results thus indicate that SAS-6 does not just serve as a scaffold for centriole assembly but also plays a key role in maintaining the structural integrity of these organelles. Future studies will be directed toward identifying how this mutant version of SAS-6 affects the critical protein-protein contacts that underlie centriole longevity.

C7019A Characterization of the Striated Rootlet Proteins of the *Paramecium* Basal Body. *A. Nabi*[1], T. Picariello[2], MS Valentine[1], J. Yano[1], J. Van Houten[1]. 1) University of Vermont, Burlington, VT; 2) UMass Medical School,Worcester, MA.

In *Paramecium,* the ciliary basal body is connected to three rootlets (Post ciliary rootlet (PCR), Transverse rootlet (TR) and Striated rootlet (SR)). The *Paramecium* cell surface is divided into units each of which has one or two basal bodies. The SR projects from the basal body toward the anterior in straight rows for several units. In *Tetrahymena*, a full-length SR is required to resist ciliary beating forces that cause the basal bodies to move out of alignment (Galati *et al*., 2014). We previously found that the depletion of the transition zone protein Meckelin results in the misaligned SR and disorganized basal bodies, reminiscent of the phenotype of the *Tetrahymena* mutant *DisA*. This mutant shows shortened SR and disorganized basal body rows. We wished to study the SR in *Paramecium* to determine its connection to Meckelin. To do so, we identified the genes for potential SR proteins. Through the expression of epitope tagged proteins, we found 9 proteins located in the SR. All of these proteins have the predicted domains of SF-assemblin protein which form the SR of *Chlamydomonas*. Proteins without this domain are not found in the *Paramecium* SR.

Immunoprecipitation (IP) of epitope tagged SR proteins followed by LC-MS/MS showed that SR family members co-IP. We purified the intact SRs and found that the epitope tagged proteins co-purify with the intact SR. LC-MS/MS analyses of the fraction of density gradients in which the SR resides show that all SR family member (SR-D, -E, -F and –G) are found together. Other proteins that co-purify are Centrin, Actin, α-, β-, and g- tubulin, Rab/Ras small GTPase.

SR-B and SR-C family members by homology but lacking the domains of SF-assemblin proteins are not located in the SR as shown by immunofluorescence, but both of are identified in the purified SR sample by LC-MS/MS.

RNAi for one of the SR family members (SR-F) showed a phenotype similar to that of the *Tetrahymena* mutant *DisA:* shortening of the SR and misaligned basal bodies rows all over the cells from the posterior to the anterior pole as compared to control cells. However, this phenotype is not found for RNAi depletion of a second SR protein SR-D4.

Acknowledgement:

LC-MS/MS analysis was supported by an Institutional Development Award (IDeA) from the National Institute of General Medical Sciences of the National Institutes of Health under grant number P20GM103449.

C7020B A NIMA-related kinase CNK4 regulates ciliary stability and length. *J. Pan*[1,2], Dan Meng[1]. 1) Tsinghua University, Beijing, Beijing, CN; 2) Qingdao National Laboratory for Marine Science and Technology, Qingdao, CN.

NIMA-related kinases (Nrks or Neks) have emerged as key regulators of ciliogenesis. In human, mutations in *Nek1* and *Nek8* cause cilia-related disorders. The ciliary functions of Nrks are mostly revealed by genetic studies, however, the underlying mechanisms are not well understood. Here we show that a *Chlamydomonas* Nrk, CNK4 that is closely related to Nek1, regulates ciliary stability and length. CNK4 is localized to the basal body region and the flagella. *cnk4* null mutant exhibited long flagella with formation of flagellar bulges. The flagella gradually became curled at the bulge formation site leading to flagellar loss. Electron microscopy shows that the curled flagella involved curling and degeneration of axonemal microtubules. *cnk4* mutation resulted in flagellar increases of IFT trains as well as its accumulation at the flagellar bulges. IFT speeds were not affected, however, IFT trains frequently stalled leading to reduced IFT frequencies. These data are consistent with a model that CNK regulates microtubule dynamics and IFT to control flagellar stability and length.

C7021C Plasma Membrane Calcium ATPase Regulates Ciliary Calcium in *Paramecium tetraurelia*. *J. Yano*, J. Van Houten. University of Vermont, Burlington, VT.

Paramecium tetraurelia, which is a cell covered in cilia*,* responds to sensory stimuli with changes in swimming behavior. Membrane potential controls beat frequency, hence speed, and graded Ca^{2+} action potentials cause the cell to turn. The physiology of the action potentials caused by activation of ciliary voltage-gated Ca^{2+} (Ca_v) channels has been known for 50 or more years. It has also been known that the Ca_v channels which are necessary for the action potential are found exclusively in the cilia. The Ca^{2+} entering the cilium through these Ca_v channels affects the ciliary beating, reversing the power stroke and transiently sending the cell swimming backward. As ciliary Ca^{2+} levels return to normal, the cell pivots in place and then swims forward in a new direction. Thus, the activation of the ciliary Ca_v channels causes cells to swim backward transiently and make a turn in their swimming paths. The pore-forming subunit proteins ($Ca_v\alpha1$) were not identified until recently when we determined the *P. tetraurelia* ciliary membrane proteome. Three $Ca_v\alpha1$ subunits were subsequently cloned and confirmed to be expressed in the cilia. We also demonstrated using interference RNA (RNAi) that these channels function as the ciliary Ca_v channels that are responsible for the reversal of ciliary beating. The ciliary membrane proteome included plasma membrane Ca^{2+} ATPases (PMCAs) that are in high abundance. RNAi for these PMCAs (PMCA 18/19) increased the duration of backward swimming, suggesting that these calcium pumps play a role in controlling the ciliary Ca^{2+} levels following the activation of the Ca_v channels. These PMCAs can be reciprocally co-precipitated with the $Ca_v\alpha1$, and can be found in the same lipid raft fractions as the $Ca_v\alpha1$. Therefore, we postulate that an important mechanism for the immediate

removal of Ca^{2+} upon activation of the Ca_v channels is the physical proximity and interaction of the ciliary calcium pumps with the channels.
Acknowledge P20GM103449.

C7022A Depletion of SUMO-conjugating enzyme Ubc9p causes nuclear defects during the vegetative and sexual life cycles of *Tetrahymena thermophila*. . *J. Forney*[1], Q. Yang[1], A. Nasir[1], R. Coyne[2]. 1) Purdue University, West Lafayette, IN; 2) J. Craig Venter Institute, Rockville, MD.

Ubc9p is the sole E2-conjugating enzyme for SUMOylation and its proper function is required for regulating key nuclear events such as transcription, DNA repair and mitosis. In *Tetrahymena thermophila* the genome is separated into a diploid germline micronucleus (MIC) that divides by mitosis and a polyploid somatic macronucleus (MAC) that divides amitotically. This unusual nuclear organization provides novel opportunities for the study of SUMOylation and Ubc9p function. We identified the *UBC9* gene and demonstrated that its complete deletion from both the MIC and MAC genome is lethal. Rescue of the lethal phenotype with a *GFP-UBC9* fusion gene driven by a metallothionein promoter generated a cell line with $CdCl_2$-dependent expression of GFP-Ubc9p. Depletion of Ubc9p in vegetative cells resulted in the loss of MICs but MACs continued to divide. Unequal partitioning of MIC DNA was observed in cells undergoing mitosis. Interestingly, expression of a catalytically inactive Ubc9p resulted in the accumulation of multiple MICs but no defect in cytokinesis was observed. During sexual reproduction endogenously tagged Ubc9p localized in the parental MAC at early stages of conjugation and later accumulated in the developing MAC. The timing and localization is consistent with our previous observations that a large increase in SUMOylation occurs in the developing MAC between 7-10 hours post mixing. Similar to Uba2p (SUMO-activating enzyme) depleted cell lines, Ubc9p depleted cell lines cannot form cell pairs after nutrient starvation and fail to mate. To analyze the function of Ubc9p during sexual reproduction we expressed the catalytically inactive Ubc9p in mating cells. A large fraction of mating pairs (42%) arrested at an early stage of macronuclear development prior to the elimination of the parental MAC. This arrest was dependent on induced expression of the mutant Ubc9p and is consistent with our observation that Ubc9p is localized in the developing macronucleus. The results demonstrate the importance of Ubc9p and the SUMO pathway in the sexual life cycle of *Tetrahymena*.

C7023B Proteinases and phagocytosis in *Tetrahymena thermophila*. *J.William. Straus*[1], Fiona Chen[1], Neila Kline[1]. 1) Vassar College, Poughkeepsie, NY; 2) Vassar College, Poughkeepsie, NY; 3) Vassar College, Poughkeepsie, NY.

Papain family cysteine proteinases have long been associated with lysosomal and phagosomal compartments. Aqueous extracts of *Tetrahymena* contain a variety of proteinases, predominantly papain family cysteine proteinases sensitive to E64 and other broad spectrum cysteine proteinase inhibitors. While there are 114 candidate cysteine proteinase genes in the *Tetrahymena* genome, few have been characterized with regard to expression, localization, and function. Membrane permeable and non-permeable fluorogenic proteinase substrates and fluorescent inhibitors localize primarily to small (≤1 μm) vesicles, usually on the surface or interior of phagosomes. Non-permeable fluorogenic substrates are taken up through the oral apparatus and incorporated into vesicles that initially align with the postoral microtubule system (detected by antibody staining), and subsequently with discrete phagosomes in transit toward the cell posterior. Zymographic analyses of aqueous cell extracts reveal 11 - 16 discrete cysteine proteinases ranging in size from about 25 kDa to over 150 kDa. A proteomic approach was used to determine which of the 114 candidate proteinases were present in aqueous and detergent homogenates. Briefly, homogenates were partially purified by affinity chromatography against immobilized inhibitor, then subjected to reduction, alkylation, and trypsin digestion.. Resulting peptides were further purified by HPLC coupled to tandem mass spectrometry and SpectrumMill analytical software. We identified 12 valid papain family cysteine proteinase sequences were detected. Future efforts will focus on additional proteomics as well as determining cellular localization, function, and gene structure of these enzymes.

57TH ANNUAL DROSOPHILA RESEARCH CONFERENCE

Poster Session Abstracts

D1001A Quantitative analysis of myosin-driven apical constriction in delaminating neuroblasts. *Yanru AN*[1,2], Guosheng XUE[1], Toyotaka ISHIBASHI[1], Chris DOE[3], Yan YAN[1,2]. 1) HKUST, Division of Life Science, Hong Kong, China; 2) HKUST, Center for Systems Biology and Human Health, Hong Kong, China; 3) University of Oregon, Institute of Neuroscience, Eugene, OR, United States.

The epithelial to mesenchymal transition (EMT) is a process important for organ formation, tissue homeostasis and tumor metastasis. We use *Drosophila* embryonic ventral nerve cord neural stem cells, the neuroblasts, as a model to study EMT events. In the neuroectoderm, for each proneural cluster of cells, one cell undergoes EMT, delaminates from the epithelium and becomes the neuroblast, while the surrounding cells remain as epithelial cells. Apical constriction is one of the key events during EMT, and in our project we aim at dissecting how the actin-myosin network drives apical constriction in a single cell delamination event.

Through imaging live embryos, we noticed that dynamic myosin loci and fibers are present across the apical surface of the delaminating neuroblasts as well as the neighboring non-delaminating cells. Quantitative analysis showed that medial myosin contractions correlate with apical cell area changes. Although the medial myosin contractile pulses are present in both delaminating neuroblasts and their non-delaminating neighbors, the medial pulses exhibit higher amplitudes and appear at higher frequency in the delaminating cells than their non-delaminating neighbors. Interestingly, when the embryos are injected with low-dose CytoD to deplete the medial myosin pulses, we noticed that the single presumptive neuroblasts still undergo pulsatile apical constriction but fail to maintain the cell area, reflex back and fail to effectively decrease their apical area over time. In these cells, the junctional myosin intensity increase precedes apical area decrease in one round of apical constriction, indicating that the junctional myosin plays a role in initiating apical constriction and the medial myosin might function to stabilize the cell shape in the delaminating neuroblasts.

D1002B An acentrosomal perinuclear microtubule-organizing center in *Drosophila* fat body cells maintains cell shape and organelle positioning. *R. Buchwalter*, Y. Zheng, J. Chen, B. Dietrick, L. R. Kao, T. Megraw. Department of Biomedical Sciences, College of Medicine, Florida State University, Tallahassee, FL 32306, USA.

While the centrosome is generally considered the main microtubule-organizing center (MTOC) in animal cells, acentrosomal MTOCs are found in diverse contexts in differentiated cells. Acentrosomal MTOCs can assemble in the cytoplasm, at the plasma membrane, nuclear periphery, adherens junction, golgi, and mitochondrion. These varied MTOCs serve roles such as nuclear positioning, establishing planar cell polarity, sperm morphogenesis, and neuron dendrite branching, depending on the cell types where they assemble. However, little is known about the assembly and molecular makeup of acentrosomal MTOCs. We have discovered an MTOC located at the nuclear periphery in larval fat body cells. Similar to adipose tissue and liver in mammals, *Drosophila* fat bodies have high metabolic activity and mobilize lipid stores and other sources to provide energy for the organism during development and under stress conditions such as starvation. We show that the fat body MTOC is comprised of at least 9 proteins that are also components of the centrosome. Specifically, a subset of centrosomal proteins that are components of the pericentriolar material (PCM) of the centrosome constitute the fat body perinuclear MTOC. We will present these components and their requirements for MTOC function and their link to the intranuclear cytoskeleton through the Linker of Nucleoskeleton and Cytoskeleton (LINC) complex. Mutations in at least two components impair nuclear position and cell shape. We also show that the MTs at this MTOC are rich in posttranslational modifications and may be unusually stable. Finally, we aim to connect the function of the fat body MTOC to the regulation of autophagy: a function we show belongs to several of the PCM proteins at the MTOC and likely a key function of the fat body to regulate metabolism (see poster by Y. Zheng *et al.* for study of the centrosome's role in autophagy).

D1003C A tissue-specific regulation of Myosin II dynamics during tube formation. *S. Chung*, S. Kim, C. Hanlon, D. Andrew. Johns Hopkins Univ, Baltimore, MD.

During embryogenesis, the salivary gland (SG) primordia change geometry from two-dimensional epithelial sheets on the embryo surface into fully internalized, three-dimensional tubes. Invagination of the SG absolutely depends on the FoxA transcription factor Fork Head (Fkh). Here, we show the temporal and spatial regulation of myosin cytoskeleton during SG invagination and reveal the tissue-specific signaling pathway that regulates it. Myosin re-localizes from cortical to apicomedial region of the SG cells prior to invagination, which is dependent on Fkh. Using both live and fixed sample imaging, we revealed that these apicomedial myosin cables are pulsatile and that they provide motive forces for cell deformation and subsequent apical constriction. We also show similar temporal and spatial re-distribution of Rho kinase (Rok), which also requires the Fkh function. We further discovered that Fkh regulates the SG expression of a secreted ligand *folded gastrulation* (*fog*) and that apicomedial localization of Rok and myosin is defected in *fog* mutant SGs, which have a range of invagination defects. Surprisingly, unlike mesodermal tissue invagination, blocking apical constriction does not prevent the SG cells from internalizing. Instead, SGs with genetic manipulation to block apical constriction still invaginate but show abnormal tissue geometry. We also provide evidence on the putative G protein coupled receptor(s) that appear to mediate the Fog signals to the Rok and myosin.

D1004A Characterization of Garz Function during Epithelial Morphogenesis. *J. Gates*, S. Andrews, R. Franz, J. Korn. Bucknell Univ, Lewisburg, PA.

Regulation of actin dynamics is essential during epithelial morphogenesis to allow cells to change shape, rearrange and migrate. Numerous proteins have been identified that influence actin dynamics including the Abelson (Abl) non-receptor tyrosine kinase and one of its targets Enabled (Ena). Previous work has shown that both Abl and Ena are required during epithelial morphogenesis in the embryo, including during the processes of dorsal closure and head involution. Furthermore, Abl appears to negatively regulate Ena during dorsal closure by reducing the levels of Ena available to assist with the formation of filopodia by the leading edge epithelial cells. To identify additional proteins that may function with Abl and/or Ena during epithelial morphogenesis, we are collaborating with Traci Stevens' lab at Randolph-Macon College. The

Stevens lab has carried out a genetic screen to identify mutations in genes that dominantly enhance or suppress the epithelial defects caused by overexpressing a constitutively active form of Abl called BCR-Abl. One of the genes they identified is *gartenzwerg* (*garz*), an ARF-GEF. We have found that mutations in *garz* dominantly enhance the head involution phenotype of *ena* homozygous mutants, but appear to have essentially no effect on the dorsal closure phenotype of these mutants. Interestingly, examination of the levels and localization of Ena and actin in *garz* mutant embryos has not yet revealed head involution defects, but has revealed dorsal closure defects that are consistent with a potential role for Garz in regulating contraction of the leading edge actin/myosin cable. To examine whether Garz may be functioning as a canonical ARF-GEF during epithelial morphogenesis we are currently testing whether mutations in *ArfGAP1* or *Arf79F* also dominantly modify the *ena* homozygous mutant phenotype. The continued examination of the roles of these proteins during dorsal closure may reveal novel roles for the Arf family of small GTPases during epithelial morphogenesis.

D1005B Characterization of a novel actin regulator, HtsRC. *J. Gerdes*, A. Hudson, K. Mannix, L. Cooley. Yale University, New Haven, CT.

Cell division of germline cells throughout the animal kingdom is characterized by incomplete cytokinesis resulting in clusters of sibling cells connected by intercellular bridges called ring canals (RC). In the *Drosophila melanogaster* female germline, ring canals acquire a robust actin cytoskeleton that supports the dramatic increase in ring canal lumen diameter over the course of egg chamber development. Genetic studies show that the *hts* gene is involved in the accumulation of ring canal F-actin, and a product of this gene, HtsRC, could be the substrate of the Kelch-Cullin3 RING ubiquitin ligase, whose function is also essential for ring canal growth. We demonstrate that HtsRC, produced by a germline-specific *hts* transcript, is necessary for actin accumulation. Using CRISPR/Cas9 directed mutagenesis of HtsRC, we obtained a series of alleles in the HtsRC coding region that block accumulation of F-actin to RCs and cause a dramatic reduction in RC size. Homozygous mutant females have severely reduced fertility. Ectopic expression of HtsRC in somatic follicle cells results in accumulation of filamentous actin aggregates. These results support the conclusion that HtsRC is necessary and sufficient for recruiting F-actin assemblies. We are now carrying out biochemical and functional analyses of the HtsRC protein in order to determine how it affects actin organization. The predicted protein contains no known functional domains and is conserved only in the Drosophila family. Therefore studying HtsRC should enhance our understanding of existing actin regulatory mechanisms, and provide new insights into the regulation of F-actin structures.

D1006C *Drosophila* myosin 7a in Phagocytosis and Eye Development. *Amy Hong*, James Sellers. NIH, Bethesda, MD, USA.

Drosophila myosin 7a (Dm7a) is an unconventional myosin required for the maintenance of the Johnston's organ (the auditory center in *Drosophila*) and the morphology of the bristle structures on the thorax. Both of these structures are formed by bundled arrays of actin. Here we show that Dm7a is involved in the process of engulfment of bacteria particles in the *Drosophila* larval hemocytes. Using the UAS/GAL4 system, we express GFP-Dm7a in the larval hemocytes where it localizes to the cortical regions of the cell and induces the formation of filopodia that are also enriched in Dm7a. We imaged the phagocytosis of fluorescently-tagged bacteria by hemocytes expressing GFP-Dm7a . When a bacterium contacts the cell surface of a hemocyte, the latter sends out a filopodium which wraps around the bacterium followed by engulfment. Occasionally an extended filopodia was seen to contact a bacterium and transport it back to the cell surface. Phagocytosis assays revealed that hemocytes from Dm7a mutant flies are defective in their ability to engulf bacteria compared to wildtype hemocytes, although bacteria do bind to their cell surface. Additionally, a lethality assay whereby larvae were challenged with bacteria show that 21% of wildtype larvae eclosed into adult flies, but less than 10% of Dm7a mutant larvae eclosed under these conditions. These results suggest a role for Dm7a in phagocytosis and in the defense mechanism of the fly. Additionally, we found that in electron microscopy sections of the adult eyes of Dm7a mutants showed missing pigment granules around the primary pigment cells and at the base of the rhabdomeres of the photoreceptor cells.

We have also identified a binding partner of Dm7a using the MyTH7 as a bait in a yeast two hybrid system and named it *Myosin 7a Binding Protein* (M7BP). M7BP protein has a potential Rab-binding domain in the N-terminus. Immunoprecipitation experiments using M7BP antibody pulled down several *Drosophila* Rab proteins. Dm7a, M7BP and Rab11 are expressed in the larval eye disc in the lens-secreting cone cells. We are in the process of investigating the functions of Dm7a and M7BP in the development of the eye.

D1007A Zasp52 is a core Z-disc scaffold protein mediating myofibril assembly by dimerizing and binding F-actin. *K. Liao*, F. Schöck. Department of Biology, McGill University, Montreal, QC, Canada.

Zasp family proteins Zasp52 and Zasp66 directly interact with alpha-actinin (Actn), colocalize at the Z-disc, and play a crucial role in myofibril assembly, the last step of muscle development. In live imaging, GFP-Zasp52 forms steadily growing Z-bodies initially evenly dispersed in myotubes, which sort out to future Z-disc locations and eventually fuse to form a contiguous Z-disc. Here we show the molecular mechanism of Zasp function. Genetic experiments demonstrate that *Zasp52* and *Actn* are both haploinsufficient genes whose gene products are required at similar stoichiometry at the Z-disc. Next, pull-down and chemical crosslinking assays show that Zasp52 dimerizes and heterodimerizes with Zasp66, likely explaining the cooperation of Zasp52 and Zasp66 and the steady growth of Z-bodies during myofibril assembly. Finally, we demonstrate through pull-down and cosedimentation assays as well as direct visualization that Zasp52 binds and bundles F-actin. Genetic interaction data indicate that binding of Zasp52 to actin thin filaments is crucial for indirect flight muscle development.

D1008B Remodeling the actin cytoskeleton by ubiquitin-dependent proteolysis. *Katelynn M. Mannix,* Juli Gerdes, Andrew Hudson, Ronit Kaufman, Lynn Cooley. Yale University, New Haven, CT.

In order for cells to perform their various functions, they must assemble and continually regulate specialized actin-based structures and networks. Remodeling of actin networks is critical to allow cells to respond to external stimuli and carry out important processes during development. In the *Drosophila* germline, ring canals (RCs) are specialized actin-based structures that function as intercellular bridges and

connect germline cells to support growth of the oocyte. RCs grow from 1 µm to 10 µm in diameter during development of the egg chamber, and their growth is driven by a robust and dynamic actin cytoskeleton. We previously found that mutations in – or inhibition of – components of a Cullin3-RING E3 ubiquitin ligase complex ($CRL3^{Kelch}$) caused aberrant accumulation of F-actin in the lumen of the RC – referred to as a *kelch*-like phenotype. Inhibition of the proteasome in the female germline also caused a *kelch*-like RC phenotype, and loss of one copy of *kelch* (the substrate recognition subunit of the ubiquitin ligase complex) enhanced the *kelch*-like phenotype, suggesting that Kelch and the proteasome function in a common pathway. We hypothesize that $CRL3^{Kelch}$ functions to target a ring canal-specific substrate for ubiquitination and proteasomal degradation, a process required for proper regulation and remodeling of the RC actin cytoskeleton during development. We are currently investigating HtsRC, a novel ring canal protein, as the substrate based on the following genetic evidence: (1) overexpression of HtsRC induces *kelch*-like RCs; (2) downregulation of HtsRC suppresses the *kelch*-like phenotype; and (3) HtsRC protein levels are dependent on Kelch protein levels. We are currently performing biochemical assays to validate HtsRC as the substrate. Specifically, we are testing if HtsRC is ubiquitinated, and if its ubiquitination is dependent on $CRL3^{Kelch}$. Further, we have made a non-degradable HtsRC by mutating all 18 lysine residues (sites of ubiquitination) to arginine, and we are testing if expression of non-degradable HtsRC induces *kelch*-like RCs. Lastly, we are performing co-IP binding assays to see if HtsRC and Kelch physically interact. Given the role HtsRC may be playing in the crucial remodeling and organization of the RC actin cytoskeleton during development, we are now interested in identifying its binding partners. To this end, we fused HtsRC to the APEX enzyme to achieve proximity-dependent biotinylation of HtsRC-interacting proteins in egg chambers. These biotinylated proteins can be captured by streptavidin beads and identified by mass spectrometry (MS). Excitingly, HtsRC::APEX MS hits include known ring canal proteins and are unique compared to Pav::APEX (another RC-specific fusion) hits, indicating that this technique can be used to identify interacting proteins with high spatial specificity.

D1009C A splice variant of Centrosomin converts mitochondria to MTOCs to facilitate sperm tail elongation in *Drosophila*. *T. L. Megraw*, J. V. Chen, L. R. Kao. Florida State University, Tallahassee, FL.

In *Drosophila* spermatids, the giant mitochondrion (nebenkern) provides a structural platform for microtubule (MT) organization to support sperm tail elongation. *centrosomin* (*cnn*) expresses several variants that fall into two major forms: a ubiquitously expressed centrosomal form (CnnC) and a non-centrosomal form in testes (CnnT). CnnC is essential for functional centrosomes, the major microtubule-organizing centers (MTOCs) in animal cells. We found that CnnT is expressed exclusively in testes and localizes to nebenkerns in spermatids. When expressed ectopically in flies or in mammalian cell culture, CnnT localizes to mitochondria in those cells too. We show that CnnT targets to the mitochondrial surface and recruits the γ-TuRC MT-nucleating complex to assemble MTs on mitochondria, converting mitochondria to MTOCs. We have mapped two separate domains on CnnT that are necessary and sufficient to 1) target it to mitochondria, and 2) to recruit the γ-TuRC and nucleate MTs, respectively. Disrupting the conserved CM1 domain in CnnT (which is shared with CnnC) abolishes the MT-nucleating function but does not block γ-TuRC recruitment, indicating that CM1 is essential for the activation of bound γ-TuRCs independent from their recruitment to MTOCs. *In vivo*, CnnT forms speckles on the surface of the nebenkern in spermatids, where it is required to recruit γ-tubulin. c*nnT* mutant males have significantly smaller seminal vesicles, shorter mature sperm tails, and reduced fertility. CnnT therefore assembles unique non-centrosomal MTOCs on nebenkerns to facilitate the morphogenesis of the extremely long sperm that are found in Drosophila.

D1010A The *Drosophila* Ninein homolog *bsg25D* cooperates with *ensconsin* in myonuclear positioning. *J. N. Rosen*, M. M. Azevedo, D. Soffar, M. K. Baylies. Sloan Kettering Institute, New York, NY.

In fruit flies as in humans, skeletal muscle cells are multinucleated with nuclei evenly spaced throughout the cell. The mechanisms by which myonuclei are correctly positioned and the consequences of mispositioning are poorly understood. In *Drosophila*, myonuclei are initially grouped together in immature muscle cells, prior to moving to the locations that they occupy in fully differentiated muscle. Our group has previously demonstrated that the conserved microtubule (MT) associated protein Ensconsin (Ens) is essential for myonuclear movement in the embryo. Recently, through a yeast two-hybrid screen, we identified Bsg25D (human ortholog: Ninein), a MT-anchoring protein, as an Ens binding partner. Muscle-specific overexpression of Bsg25D causes a complete block in myonuclear movement in the embryo, recapitulating the *ens* null phenotype. Genetic interaction and rescue experiments combined with colocalization studies suggest that exogenous Bsg25D exerts its effect by sequestering Ens away from MTs where it normally functions. Later in development, Bsg25D-overexpressing larval muscles exhibit severely mispositioned nuclei and dramatic alterations in MT organization; larval motility is reduced, demonstrating a loss of muscle activity. To complement our overexpression studies, we generated a *bsg25D* null mutant. Even though *bsg25D* mutant muscles are normal, loss of *bsg25D* enhances myonuclear positioning defects in *ens* heterozygotes. Similarly, *bsg25D* mutant flies have nearly wildtype viability, but loss of *bsg25D* in an *ens*-compromised background causes embryonic lethality. We are currently investigating the hypothesis that an Ens-Bsg25D interaction regulates MT dynamics at the myonuclear envelope, a critical MT organizing center in muscle cells (which lack centrosomes). The functions of centrosomal proteins in muscle are unknown, and this is the first evidence for a centrosomal protein participating in myonuclear positioning. As certain muscular dystrophies characteristically feature mispositioned myonuclei, our results will shed light on human disease.

D1011B Regulation Of Actomyosin Network By Homophilic Cell Adhesion Molecule Echinoid During Epithelial Morphogenesis. *Rahul Rote*, Arsida Noçka, Laura Nilson. Department of Biology, McGill University, Montreal, Quebec, CA.

Cell shape changes during epithelial morphogenesis are driven by differential distribution of cell adhesion molecules, cytoskeletal components and polarity factors. Echinoid (Ed) is a homophilic cell adhesion molecule required in normal epithelial morphogenesis during embryonic dorsal closure and ovarian follicular epithelium development. Both of these processes are characterized by loss of Ed from a defined group of cells, which leads to the formation of a supracellular actomyosin cable and smooth contour at the interface of Ed-positive (Ed) and Ed-

negative (no-Ed) cells. Ed is also lost from the Ed-positive cells at this interface, due to the absence of a homophilic binding partner in the adjacent cells, resulting in a planar polarized distribution of Ed in these cells. We are testing two alternate hypotheses to explain this phenotype. The first is that planar polarized distribution of Ed guides the formation of actomyosin cable at the interface devoid of Ed. The second hypothesis is that Ed simply functions as a negative regulator of the actomyosin network and absence of Ed at an interface leads to actomyosin enrichment at that particular interface.

Quantification of actin using fluorescently-labeled phalloidin, and myosin using fluorescently labeled heavy or light chain of Myosin II, revealed that significant enrichment of actin and myosin occurs at interfaces between Ed/no-Ed cells as well as no-Ed/no-Ed cells. Cells lacking Ed are also apically constricted, consistent with higher actomyosin contractility. These observations seem to support the negative regulator hypothesis. However, Ed/no-Ed interfaces exclusively display a smooth border, loss/disruption of the polarity protein Par3/Bazooka and enrichment of the actomyosin contractility regulator Rho-Kinase. We also studied distribution of myosin tagged with GFP and RFP–in adjacent wild type (WT) and ed mutant cells respectively. We observed that myosin polarization is stronger in the WT cells at the ed clone border than in the adjacent ed mutant cells, indicating that polarization of Ed has a stronger effect on myosin than the global absence of it. These observations are consistent with the planar polarization hypothesis. Thus, the regulation of actomyosin network by Ed may encompass a variety of interactions between downstream effector molecules involved in cell polarity and cytoskeletal dynamics.

D1012C Novel mechanisms of phosphoregulation of Moesin by Clic in *Drosophila* rhabodomere formation. *S. Tanda*, R. Hikida, M. Berryman. Ohio Univ, Athens, OH.

Moesin (Moe) is a key component to link the actin cytoskeleton to the plasma membrane for stable surface structures such as microvilli. Moe function depends on phosphorylation in its actin binding domain. Phosphorylated Moe (p-Moe) is an active form that binds to both actin filaments and membrane proteins to tether them together. Levels of p-Moe are regulated by a kinase, Slik, and a phosphatase, Pp1-87B, which work antagonistically. Clic (Chloride Intracellular Channel) is proposed to interact with Moe and regulate levels of p-Moe. For example, loss of Clic function results in increased levels of p-Moe in the larval salivary gland. To elucidate how Clic regulates p-Moe levels in cell types rich in actin-based surface structures, we chose the rhabdomeres of photoreceptors in the compound eyes of *Drosophila melanogaster*. The rhabdomeres are a cylinder like surface structure consisting of ~60,000 microvilli. As we observed in the larval salivary gland, p-Moe levels were elevated in Clic-deficient clones in the pupal retina. The rhabodomeres are extremely sensitive to levels of Moe phosphoregulators like Slik. We examined rhabodomere structures in different genetic backgrounds using transmission electron microscopy. We changed expression of Slik and Pp1-87B in a wild-type as well as Clic-deficient background. We also examined rhabdomere structures in loss-of-function as well as gain-of-function of Moe in the presence or absence of Clic. We found that Clic suppresses Slik and Pp1-87B functions. Effects of Clic on these Moe phosphoregulators also depend on the level of Moe. Clic showed more pronounced effects on Slik than Pp1-87B when less Moe was available in photoreceptors, while Pp1-87B activity was more suppressed by Clic when Moe is more abundant. Based on these findings, we propose that Clic plays a critical role in maintaining a proper level of p-Moe in photoreceptors in the compound eye.

D1013A Investigating patterns of cell interactions during epithelial folding. *Hannah G. Yevick*[1], Norbert Stoop[2], Jörn Dunkel[2], Adam Martin[1]. 1) MIT Biology, Cambridge, MA; 2) MIT Mathematics, Cambridge, MA.

Correct tissue shape is essential for proper tissue function. How groups of hundreds or even thousands of cells coordinate to yield stereotypic shape change through large-scale movements is still poorly understood. One way for cells to interact is through direct mechanical coupling. In fact, largescale networks of actomyosin connections, linking across neighboring cells are present in a wide range of developing tissues across various model organisms. The *Drosophila* ventral furrow represents one such system for studying supracellular networks. During furrow formation cells coordinate constrictions to yield tissue-wide bending. The tissue possesses a dynamic myosin network which fully forms prior to folding. Little is known, however, how mechanical information in the network guides reproducible tissue constriction. We have developed a novel approach, integrating mathematical concepts from topological feature analysis and network theory to map the previously unquantifiable myosin network across hundreds of cells in the developing ventral furrow tissue. Our approach aims to identify a novel unit of cooperation between the cell and the tissue scale over which cells synchronize. We have identified an initial growth phase and a subsequent contractile phase in the network. Our framework allows us to explore how geometric and topological patterns in the myosin network inform tissue-level constriction.

D1014B Syncytial embryo cleavage through an actomyosin Goldilocks effect set by Rho kinase and myosin phosphatase. *Y. Zhang*, T. Jiang, C. Yu, T. Harris. University of Toronto, Toronto, Ontario, CA.

For cytokinesis, the physical division of two nascent cells, actomyosin networks drive cleavage furrow ingression. During this process, network contractility is promoted through myosin phosphorylation mediated by Rho kinase (Rok) and reversed by myosin phosphatase. Cleavage of the early *Drosophila* embryo involves incomplete cytokinesis to maintain syncytial organization. Furrows ingress as lateral membranes, but actomyosin networks at their basal tips do not constrict to close the base of the cells. How myosin activity affects membrane ingression remains unclear. Previous work suggested that myosin is not essential for furrow ingression, whereas other studies indicated that actomyosin networks are actively inhibited to prevent full cell division. To investigate whether myosin is involved in furrow ingression, we perturbed Rok by RNAi. We found that myosin is lost from furrow membranes and furrows failed to ingress when Rok was severely depleted. Myosin regulatory light chain (MRLC) RNAi mimics the defects seen with Rok-RNAi, indicating myosin is required for proper furrow organization. To test the role of myosin de-phosphorylation, we targeted the myosin binding subunit of myosin phosphatase (Mbs) by RNAi. Loss of Mbs increased myosin accumulation at the base of furrows and induced constriction at these sites. As a result, basal membranes closed abnormally and impinged on

nuclei. To confirm the effects were due to excessive myosin activity, we also overexpressed Rok or phosphomimetic-MRLC and observed similar basal membrane closure, indicating Mbs keeps myosin activity in check during furrow ingression. To dissect how myosin activity is controlled by this phosphor-regulation, we compared the furrow localization of myosin, Rok, and the catalytic subunit of myosin phosphatase, Flapwing (Flw). The cortical level of all three proteins changed over the cell cycle. As new cleavage furrows formed, levels of all three protein gradually increased on the furrow membrane, with enrichment at their basal tips Together, these data suggest that syncytial embryo cleavage depends on myosin activity that is not too low or too high, a Goldilocks effect, and that the proper range of activity is set locally by the counteracting activities of Rok and myosin phosphatase.

D1015C The Role of Retromer-Dependant Recycling in Epithelial Polarity and Morphogenesis. *K. Al Kakouni*[1], K. Harris[2], U. Tepass[1]. 1) University of Toronto, Toronto, ON, CA; 2) MIT, Cambridge, MA, USA.

Epithelial sheets are barriers that subdivide the body into physiologically distinct compartments. To achieve this, epithelial cells acquire apical-basal polarity. Polarity regulators associated with the apical membrane include atypical protein kinase C (aPKC), Cdc42, and the transmembrane protein Crumbs. Moreover, the vesicle trafficking machinery contributes to epithelial polarization by facilitating the transport of proteins and lipids to apical and basolateral domains. The mechanisms by which polarity proteins interact with the trafficking machinery remain unclear. Our previous work showed that the regulation of Crumbs endocytosis or recycling by Cdc42 and its downstream effector aPKC is important for epithelial integrity This led us to hypothesize that aPKC has phosphorylation targets in the vesicle trafficking machinery.

Bioinformatic analysis suggests that aPKC may have several phosphorylation targets in the trafficking machinery, including the retromer component Vps26. The retromer retrieves proteins from endosomes and transports them back to the Golgi or to the plasma membrane. Our data suggest that aPKC, when activated by Cdc42, phosphorylates Vps26, and as a result increases the activity of the retromer complex. We generated Vps26 mutations and found that *Vps26* maternal/zygotic mutants show loss of epithelial integrity and defects that resemble those observed in *crumbs* or other polarity mutants. Normal, phosphomimic and non-phosphorylatable isoforms of Vps26 form a complex with aPKC *in vivo*, and, expression of phosphomimic Vps26 suppresses the Cdc42 loss-of-function phenotype. Furthermore, Cdc42 or aPKC compromised embryos show loss of Crumbs from the plasma membrane, and its accumulation in Vps26 positive endosomes. These findings suggest that the retromer is recruited to endosomes in order to recycle Crumbs but is unable to do so in the absence of aPKC phosphorylation of Vps26. We propose therefore that aPKC phosphorylation of the retromer is essential mechanism for maintaining epithelial polarity.

D1016A Investigating the Role of Rab Proteins in Drosophila Photoreceptor Apical Vesicle Trafficking. *A. Laffafian*, U. Tepass. University of Toronto, Toronto, Canada.

Protein trafficking is an essential cellular process and required, for example, for cell signaling and membrane polarization. Problems in protein trafficking have been linked to many human diseases such as cancer and Alzheimer's disease. We investigate the mechanisms of vesicle trafficking of apical proteins in Drosophila photoreceptor cells (PRCs). Individual ommatidia in the Drosophila compound eye house 8 PRCs that surround a matrix filled lumen. Our goal is to investigate the role of Rab proteins in vesicle trafficking of apical proteins including the photopigment Rhodopsin (Rh), which localizes to the rhabdomere, the apical determinant Crumbs (Crb), which is enriched in the stalk membrane, and the proteoglycan Eyes shut (Eys), which is secreted into the interrhabdomeral space. Rab proteins are universal regulators of vesicle transport and more than 30 Rab proteins are found in Drosophila. Rab11, for example, is important in the delivery of rhabdomere bound proteins like Rh (Satoh et al., 2005, Development. 132: 1487-1497). We have examined the localization of Eys, Crb, and Rh, in animals with compromised Rab proteins using available RNAi and dominant negative (DN) lines. One example is expression of RabX5-DN, which leads to the cytoplasmic accumulation of Rh. We are currently in the process of determining the subcellular localization and producing CRISPR mutants for select Rabs that show interesting trafficking defects.

D1017B Cell chirality is a novel and evolutionarily conserved cell polarity that drives left-right asymmetric morphogenesis. *K. Matsuno*, A. Okubo, S. Utsunomiya, M. Inaki, T. Sasamura. Osaka University, Toyonaka, Osaka, JP.

Most macromolecules found in cells are chiral (an object is chiral if it is distinguishable from its mirror image). However, chirality of cells has not been noticed until very recently. In our attempt to understand the mechanisms of left-right (LR) asymmetric development in *Drosophila*, we revealed that cells have intrinsic chirality in their structure.

Mechanisms of LR asymmetric development are evolutionarily diverged and remain elusive in invertebrates. *Drosophila* has various organs, such as the gut, testes, and male genitalia, which show stereotypic LR asymmetry. Our research focused on the LR asymmetric development of the embryonic gut that is first organ to show LR asymmetry during *Drosophila* development. The embryonic hindgut rotates counterclockwise 90 degree during its LR asymmetric morphogenesis. The active force driving this rotation originates from hindgut epithelium without any contribution of cell proliferation or apoptosis. Our three dimensional analysis of hindgut epithelium structure revealed that epithelial cells show chirality in their shape, which is the first demonstration of cell chirality *in vivo*. Our computer simulation analysis suggested that cell chirality drives the LR asymmetric rotation of the hindgut, so demonstrating the biological function of cell chirality for the first time. Similar cell chirality was found in other fly organs showing LR asymmetry, and its contributions to the LR asymmetric morphogenesis of these organs were similarly indicated.

To identify genes involved in LR asymmetric development, we have conducted genetic screens covering most of fly genome. We identified *Myosin31DF* (*Myo31DF*), encoding *Drosophila* Myosin ID, as mutants in which LR asymmetry becomes sinistral (mirror image of wild-type counterpart). These results suggest that the default state of handedness is sinistral in *Drosophila*, and the default handedness is reversed by Myo31DF in wild type. Interestingly, cell chirality also becomes mirror image in these mutants. Our mosaic analyses involving *Myo31DF*

mutant revealed that cell chirality is intrinsically formed in individual cells.

Recently, cell chirality was reported in various vertebrate cultured cells, and these analyses suggested evolutionarily conservation of cell chirality. However, biological roles of cell chirality remain unknown in vertebrates. Thus, the *Drosophila* system may provide important insights into the functions of cell chirality and the genetic mechanisms of its formation.

D1018C Tension-dependent junction remodeling repositions polarity proteins and coordinates EMT progression. *M. Weng*[1,2], E. Wieschaus[1,2]. 1) Princeton University, Princeton, NJ; 2) The Howard Hughes Medical Institute.

Although Snail (Sna) is the driving factor of epithelial-mesenchymal-transition (EMT), loss of adherens junctions and polarity in *Drosophila* gastrula is delayed until mesoderm is internalized, despite the early expression of Sna in that primordium. By combining live imaging and quantitative image analysis, we show that contractile myosin on the apical surface of the epithelia that triggers the internalization of the tissue, also strengthens and repositions the adherens junctions, which in turn repositions and delays the complete loss of the polarity proteins until the completion of tissue morphogenesis. We found that before the initiation of mesoderm internalization, expression of Sna in mesodermal epithelia leads to a series of changes that resembles partial EMT: decreased localization of polarity proteins such as Bazooka (Baz) and aPKC, downregulation of cortical actin, and disassembly of adherens junctions. Similar phenotypes can be induced by ectopic expression of Sna in ectoderm. Such Snail-dependent junction loss appears to be mediated by loss of Baz, as Baz knockdown leads to a similar loss of adherens junctions whereas Baz localization maintains in the absence of junctions. The decrease in junction level however is reversed upon the activation of apical myosin despite the continued Sna expression. Adherens junctions then are shifted from subapical position to apical position and strengthened in a myosin-dependent manner. Although Baz is not recovered as much as the junctions and results in decreased ratio between Baz and junctions, its level is maintained until tissue internalization. By tracking individual junction and Baz clusters, we found that as the junction clusters shift apically, Baz is often left behind to diminish but is quickly restored in the newly positioned junction clusters. This junction-directed polarity redistribution can override the polarity protein redistribution mechanism that drives basal junction shift during dorsal folds formation, as ectopic activation of myosin in those cells can induce apical repositioning of junctions and Baz and abolishes the dorsal folds. In summary, to prepare timely EMT of mesodermal tissue early expression of Snail induces partial EMT meanwhile to ensure proper folding of the tissue preceding EMT, the contractile actomyosin, the same machinery that drives the morphogenic event, is used to pause the partial EMT by reorganizing adherens junctions followed by the redistribution of polarity proteins.

D1019A Differential Subcellular Trafficking of Membrane Proteins in Secondary Cells of the *Drosophila* male Accessory Glands. *Felix Castellanos*, Benjamin Kroeger, Shih-Jung Fan, Mark Wainwright, Siamak Redhai, Carina Gandy, Clive Wilson. University of Oxford, Oxford, GB.

The male accessory glands of *D. melanogaster* are paired structures whose secretory products constitute an essential fraction of the seminal fluid and play a critical role in reproduction. Two morphologically different populations of secretory cells form a monolayered epithelium in the accessory glands. The less abundant (~5%) and larger spherical cells, collectively known as secondary cells (SCs), localise at the distal ends of each lobe.

A number of different subcellular compartments can be identified in SCs by assessing acidity and other biochemical properties such as the differential Rab GTPase localisation. For example, Rab7 localises to the surface of large acidic late endosomes and lysosomes, while Rab11 localises to the limiting membrane of non-acidic secretory vacuoles that contain dense-core granules (DCGs).

We are currently investigating how secretory compartments and different populations of intraluminal vesicles (ILVs) are formed in adult SCs. Many cells secrete vesicles that are thought to be formed in the late endosomal multivesicular body (MVB) and are ultimately released by compartment fusion to the cell surface. These so-called exosomes can fuse with target cells, transferring a broad range of biomolecules.

Using state-of-the art imaging and pulse-chase analysis of membrane proteins tagged with fluorescent markers, we have characterised the selective trafficking routes taken by different fusion proteins to reach their final subcellular destinations. These proteins localise to the plasma membrane, in addition to non-acidic vacuolar limiting membranes, their DCGs and ILVs. Using a fusion protein that traffics to DCGs, we are currently testing several molecules for putative roles in DCG biogenesis (e.g. lipid modifying enzymes, as well as the ESCRT genes). Based on these experiments, we have started to develop a mechanistic model to explain cargo trafficking to DCGs, which unexpectedly implicates ILVs. Our results contrast with other data using a previously characterised human CD63-GFP exosome marker, which traffics to other compartments and is loaded on to a different subset of ILVs.

This work sheds new light on the mechanisms regulating DCG compartment biogenesis and the different trafficking routes taken by cargos to reach these compartments. Ultimately, it may inform our understanding of DCG regulation in processes controlling homeostasis, such as glucose-dependent insulin secretion by pancreatic beta cells.

D1020B RPTPs mediate the temporal control of *Drosophila* airway maturation through an interaction with the non-receptor tyrosine kinase Btk29A and its effector WASH. *V. Tsarouhas*[1], D. Liu[1], G. Tsikala[1], K. Zinn[2], C. Samakovlis[1]. 1) Stockholm University, Stockholm, Sweden; 2) California Institute of Technology, Pasadena, CA, USA.

The respiratory tubes of mammalian lungs and the *Drosophila* tracheal system undergo a series of maturation events at the end of embryogenesis. An important transition during *Drosophila* airway maturation is the clearance of the solid luminal material before the replacement of luminal liquid by gas. We had shown earlier that luminal protein clearance depends on a wave of apical endocytosis but its regulation is largely unknown. Here we show that *Drosophila* type III receptor tyrosine phosphatases (RPTPs), Ptp4E and Ptp10D restrict tube growth and apical endocytosis during embryonic airway maturation. Live imaging of mutant embryos lacking both RPTP genes revealed an earlier clearance of GFP-tagged luminal proteins compared to wild type embryos. Genetic alterations in endocytosis by the generation of

ptp4E10D and *rab5* or *vps45* triple mutants could ameliorate luminal clearance phenotypes suggesting elevated endocytic levels in *ptp4E10D* mutants. Quantifications of the intercellular vesicles through an established endocytic Dextran assay in live embryos revealed a direct role of RPTPs in the temporal control of luminal endocytosis. Endo-lysosomal analysis showed an enhanced endocytic trafficking oriented towards the degradation pathway in *ptp4E10D* mutants. Following a short scale genetic screen we identified the non-receptor tyrosine kinase Btk29A as a downstream target of RPTPs with *ptp4E10D;btk29A* triple mutants showing rescue in tube size and premature luminal clearance. Immuno-precipitation experiments from embryo extracts confirmed a physical interaction between Ptp10D and Btk29A and revealed binding of Btk29A to actin nucleator protein WASH. Single mutant analysis showed that both Btk29A and WASH proteins are required for the endocytic clearance of luminal material. Interestingly, loss of *wash* in *ptp4E10D* mutants suppressed the tube size defects suggesting an antagonistic role of RPTPs in Btk29A/WASH pathway. In summary, we show that RPTPs and Btk29A have antagonistic functions on WASH mediated actin polymerization to control the timing of luminal protein clearance in *Drosophila* airways.

D1021C Fat2 and Lar define a planar signaling system controlling collective cell migration. *Kari Barlan*, Maureen Cetera, Sally Horne-Badovinac. THE UNIVERSITY OF CHICAGO, CHICAGO, IL.

Collective migration of cells in an epithelial sheet underlies tissue remodeling events associated with morphogenesis, wound repair, and the metastatic cascade. Similar to individually migrating cells, each epithelial cell forms actin-based protrusions at its leading edge that form new adhesions to the extracellular matrix (ECM). Each cell also releases cell-ECM adhesions at its rear to allow the trailing edge to retract and cell body to advance. These migratory behaviors must be coordinated with outstanding precision to allow sheet migration to occur. Each cell's protrusions extend beneath the trailing edges of the cells in front, similar to overlapping shingles on a roof. Thus trailing edge retraction in the leading cell must be coordinated with protrusion formation in the trailing cell so that the two cells don't compete to adhere to the same region of ECM. Studying the migration of the follicular epithelium, we find that the cadherin Fat2 and the receptor phosphatase Lar form the core of a planar signaling system that coordinates leading edge protrusion and trailing edge retraction between neighboring cells. Fat2/Lar signaling is similar to the Frizzled/VanGogh and Fat/Dachsous planar cell polarity (PCP) signaling that is used to organize many epithelial tissues, in that Fat2 and Lar localize to opposite sides of each cell and mediate communication across cell-cell boundaries. However, whereas the PCP systems operate near the apical surface to transmit long-range information across the tissue, the Fat2/Lar system operates near the basal surface to transmit short-range information between adjacent cells. Previously, Fat2 was shown to localize to the trailing edge of each migrating cell. Our analysis in mosaic epithelia reveals that Fat2 signals from the trailing edge to non-cell-autonomously induce leading edge protrusions in the cell directly behind. Conversely, we find that Lar localizes to the leading edge, and is cell-autonomously required for protrusions. We also observe a trailing edge retraction defect in both *Lar* and *fat2* mosaics. In this process, however, Fat2 plays a cell-autonomous role, while Lar plays a non-cell-autonomous signaling role. Further, we provide evidence suggesting that Fat2 and Lar participate in a protein complex that spans cell-cell boundaries. Together our data suggest that bidirectional signaling between Fat2 and Lar across cell-cell interfaces coordinates leading and trailing edge behaviors between neighboring cells to promote collective cell migration.

D1022A Analysis of chiral cellular dynamics in left-right asymmetric rotation of *Drosophila* hindgut. *M. Inaki*[1], H. Honda[2], K. Matsuno[1]. 1) Osaka Univ., Toyonaka, Osaka, JP; 2) Kobe Univ., Kobe, Hyogo, JP.

Although most of organisms appear bilaterally symmetric in their body shapes, many of their internal organs show left-right (LR) asymmetry. To understand mechanisms underlying LR asymmetry formation of internal organs, we are using *Drosophila* embryonic hindgut as a model system. The *Drosophila* hindgut is first formed as a bilaterally symmetric structure consisting of columnar epithelial cells, rotates 90 degree in counter clockwise direction, and eventually exhibits an LR asymmetric morphology. It has been shown that before rotation, hindgut cells have chirality with LR asymmetric apical surfaces and that the cell chirality is involved in the LR asymmetric rotation of the hindgut. However, it is unclear how cellular chirality contributes to whole organ rotation. The cellular dynamics during rotation is also unknown since previous studies were based on observations of fixed hindgut samples. In this study, we tried to clarify cellular dynamics during LR asymmetric rotation and relationships between the dynamics and the cell chirality. First, we performed computer simulations of hindgut epithelium using a vertex model. Based on predictions from the simulations, we carried out live-imaging of hindgut epithelial cells during rotation. As results, we found that hindgut cells change their relative positions to their subjacent cells, as sliding leftwards (in rotation direction) against subjacent cells. In *Myosin31DF* mutants, in which the cell chirality and the direction of rotation are inverted, cells slide in opposite direction. These results suggested that "cell-sliding" contributes to the LR asymmetric rotation of the hindgut and the cell chirality is reflected by the direction of the cell-sliding. In this study, we found a novel cellular dynamics, chiral cell-sliding, which drives LR asymmetric morphogenesis.

D1023B Out-of-Step is a novel serine/threonine kinase that directs myotube pathfinding. *Aaron N. Johnson*, Brenna Clay. Univ Colorado Denver, Denver, CO.

Skeletal muscles attach to the skeleton via tendons, and skeletal movement requires a tight physical interaction between skeletal muscles and tendon cells. Myotubes are the skeletal muscle precursors, and nascent myotubes are guided to tendon cells through largely unknown mechanisms. In a genetic screen for regulators of embryonic body wall muscle development, we identified the Out-of-step (*ofs*) phenotype in which nascent myotubes failed to extend toward tendon cells in a synchronized manner. The *ofs* allele mapped to a previously uncharacterized serine/threonine kinase that is orthologous to mammalian Vaccinia Related Kinase (VRK), and neither VRK nor Ofs have been studied in the context of myogenesis. Using LifeAct.GFP, we found that *ofs* myotubes failed to extend filopodia during pathfinding. The leading edges of *ofs* myotubes initiate outgrowth but are unable to reach and attach to tendon cells. By RNA-seq, we found that Notch target genes in the Enhancer of Split Complex [E(Spl)-C] are enriched in *ofs* embryos. We are testing the hypothesis that contact dependent Notch signals inhibit

myotube outgrowth, and that Ofs modulates the intracellular response to Notch. This study is the first to identify a protein kinase that directs myotube pathfinding, and will provide essential insights into the mechanisms by which filopodia probe the extracellular environment during cell migration.

D1024C Twinstar/cofilin is required for regulation of epithelial integrity and tissue growth in *Drosophila*. *C. Ko*, Y. G. Kim, T. P. Le, K. W. Choi. KAIST, Yuseong-gu, Daejeon, KR.

Regulation of actin assembly and depolymerization is important for the organization of epithelia. Recent studies have shown that the actin-capping proteins are required to prevent cell extrusion and inappropriate activation of Yorkie (Yki) activity in *Drosophila*, implicating the importance of actin regulation for epithelial integrity and Yki-dependent tissue growth. However, the role of Twinstar (Tsr), the *Drosophila* homolog for cofilin/actin depolymerization factor (ADF), in epithelial integrity and Hippo signaling is unknown. Both capping proteins and Tsr are crucial components of actin depolymerization process. Therefore, like capping proteins, Tsr may participate in epithelial integrity and tissue growth. Hence we investigated the consequence of Tsr reduction on epithelial integrity and development in wing imaginal disc, using GAL4-UAS and FRT-FLP methods. We show that reduction of Tsr in wing imaginal disc induces not only F-actin accumulation but also ectopic expression of Wingless (Wg) and Yki target gene expanded (ex). Knockdown of Yki in Tsr-depleted cells reduced the level of ectopic Wg expression. Reduced Tsr also led to downregulation of cell junction proteins and extrusion of affected cells from the basal part of the epithelium. Rho GTPase 1, a known actin modifier protein, was upregulated in Tsr-depleted tissue, supporting the Tsr function in the inhibition of cell extrusion from the epithelium. Tsr is also required for blocking cell death and c-Jun N-terminal kinase (JNK) signaling, as loss of Tsr induced both apoptotic features and upregulation of JNK downstream target genes. Ectopic JNK activation induced caspase activation but did not cause cell extrusion in this case, hence JNK activation is not sufficient condition for invasive cell movement. Further, the invasiveness of Tsr-depleted cells was not suppressed by inhibition of cell death or JNK signaling, and it was enhanced in Tsr knockdown cells with cell death inhibitor P35, indicating a critical role of Tsr in cell migration control. In contrast, Yki upregulation was significantly suppressed by cell death inhibition. Taken together, our data suggest that Tsr is required for cell survival and tissue growth by regulating JNK and Yki signaling while maintaining the epithelial integrity by controlling cell junctions. This study provides an insight into potential roles of ADF/cofilin in invasive cell migration and tumor suppression in higher animals.

D1025A Inhibition of Protein Phosphatase 1 activity switches border cells from a collective to single cell mode of migration. *J. A. McDonald*[1], D. Ramel[2], G. Aranjuez[3], A. Burtscher[3], K. Sawant[1], X. Wang[2]. 1) Division of Biology, Kansas State University, Manhattan, KS; 2) LBCMCP, Centre de Biologie Intégrative (CBI), Université de Toulouse, CNRS, UPS, France; 3) Lerner Research Institute, Cleveland Clinic, Cleveland, OH.

Cells often migrate in distinctly organized groups, or 'collectives', to form, remodel and sculpt tissues and organs. The mechanisms underlying how cells in collectives stay together and coordinate their movement rather than migrate as individual cells are still poorly understood. *Drosophila* border cells undergo collective cell migration during oogenesis. Border cells travel as a cohesive cluster of 6-10 cells between the large nurse cells to reach the oocyte. While several serine-threonine kinases and their target proteins have known roles in border cell migration, the functions of serine-threonine phosphatases are unknown. Here we show that Protein Phosphatase 1 (PP1) maintains the collective cohesion and migration of border cells. Inhibition of PP1 activity, either through the endogenous inhibitor NiPP1 or by knockdown of multiple PP1 catalytic subunits, causes border cells to round up and completely dissociate from the cluster while they are migrating. These individual border cells have altered motility, with protrusion formation between cells, and slower movement. Rac activity is still enriched in the leading border cell, showing that guidance signaling and directionality are not affected. However, levels of E-cadherin between cells are strongly reduced. Moreover, myosin localization is altered and F-actin becomes enriched around individual border cells rather than at the periphery of the entire border cell cluster. Together, these cellular alterations contribute to the inability of PP1-inhibited border cells to adhere tightly to each other and move as a group. Thus, PP1 activity promotes a collective rather than individual cell migration mode.

D1026B The vesicle fusion regulator α-SNAP is required for STAT pathway activation and induction of cell motility. *A. Saadin*, M. Starz-Gaiano. University of Maryland Baltimore County, Baltimore, MD.

Cell migration is a fundamental and precisely regulated event during animal development, immune response and wound healing. It can also lead to detrimental outcomes such as tumor metastasis and atherosclerosis. Hence, unraveling the detailed mechanism of this process is crucial to advance our understanding of development and to improve therapeutics. A cluster of cells termed the border cells in Drosophila egg chambers provides a well-founded and genetically tractable system to study cell migration *in vivo*. The border cell cluster, originating from the follicular epithelium, is composed of four to six migratory border cells and a pair of non-motile polar cells. Polar cells induce the specification of border cells by secreting the Unpaired (Upd) ligand, which activates the well-conserved Janus Kinase/Signal Transducer and Activator of Transcription (JAK/STAT) signaling pathway in the neighboring follicle cells. Border cells then wrap around polar cells and migrate between nurse cells toward the developing oocyte. In an RNAi screen to identify novel regulators of cell migration, we uncovered a requirement for *α-Soluble NSF Attachment Protein* (*α-SNAP*) in border cell cluster specification. α-SNAP is known to function in synaptic transmission, membrane fusion, and vesicle trafficking by facilitating association of N-ethylmalemide-Sensitive Factor (NSF) and SNAP Receptor (SNARE) during vesicle fusion. RNAi-mediated depletion of *α-SNAP* in the anterior follicle cells, including the polar cells, results in egg chambers that lack both polar

and border cells. Mosaic mutant analysis for *α-SNAP* supports these results, and over-expression of *α-SNAP* rescues the knockdown phenotype, confirming the specificity of the RNAi reagents. Immunofluorescent labeling reveals the localization of α-SNAP at the periphery of both the polar and border cells. Over-expression of viral anti-apoptotic gene, *p35*, in the *α-SNAP* depleted egg chamber verifies that the lack of a border cell cluster is due to impaired signaling, not apoptosis. Through suppression/enhancement assays with various regulators of the STAT signaling pathway and *α-SNAP* RNAi, we found that *α-SNAP* functions upstream of *upd* in the polar cells to regulate the JAK/STAT signaling pathway during border cell cluster formation. Among several SNAREs we examined, only *syntaxin 1A* recapitulates the lack of border cell cluster phenotype when depleted in the anterior follicle cells, indicating that it likely functions with *α-SNAP* during border cell cluster formation. Therefore our study identified a specific new role for *α-SNAP* in STAT-mediated motile cell specification.

D1027C *Drosophila* Fondue is a critical extracellular matrix organizer during muscle attachment and coagulation. *Nicole M. Green*[1], Nadia Odell[2], Cheryl Clark[1], Mitch Dushay[3], Erika R. Geisbrecht[1]. 1) Kansas State University, Manhattan, KS; 2) University of Missouri-Kansas City, Kansas City, MO; 3) Cornell University, Ithaca, NY.

The orchestration of cells to form and maintain larger structures is a complex and dynamic process reiterated throughout organismal development. Connective extracellular matrix (ECM) provides structural integrity and flexibility to allow for stresses associated with movement and mechanical force transmission in epithelial and muscle tissues. In *Drosophila*, perturbation of ECM results in weakened or malformed muscle attachment sites (MASs) that detach, making the MAS an excellent model for studying this phenomenon. We have identified a new role for a secreted hemolymph protein called Fondue (Fon) in *Drosophila* muscle attachment. Previous studies of Fon focused on its role in clot stability and innate immune response. However, early pupal lethality and abnormal pupal morphology in unchallenged individuals indicated that Fon had a developmental role. Transgenic flies containing a tagged Fon construct revealed that Fon-GFP accumulates at both indirect and direct attachment sites in L3 larvae. Both *fon* mutants and *fon* RNAi fillets contained body wall muscles that detach with large gaps between subsets of muscles across hemisegments. Using TEM to analyze MAS ultrastructure, we found that *fon* mutants had disrupted cuticle and tendon architectures, a lack of muscle-tendon interdigitation, and a loss of electron-dense matrix accumulation. Together, the TEM data and abnormal muscle morphologies observed in L3 fillets indicate that Fon is a critical regulator of ECM organization and overall MAS integrity. In a *fon* mutant sensitized background, we identified both *tig* and *tsp* as candidate interactors of Fon at the MAS. RNAi knockdown of either transcript increased detachment phenotypes compared to *fon* heterozygotes or candidate RNAi fillets alone. Tig has also been identified as a component of the hemolymph clot. We were able to identify one other secreted hemolymph protein, Lsp1γ, that results in muscle detachment upon RNAi knockdown. Using an Lsp1γ-GFP construct, we observed Lsp1γ-GFP localizing in a tendon-associated pattern at the MAS. From this data we can conclude that the analogous structures of the hemolymph clot and the muscle attachment site require a unique and overlapping set of secreted proteins in *Drosophila melanogaster*, identifying a connection between innate immune and muscle development processes.

D1028A implication of the basement membrane and adhesion complexes during leg morphogenesis in drosophila. *A. ARNAUD*, B. Monier, T. Mangeat, M. Suzanne. LBCMCP, TOULOUSE, FR.

Mechanical signals are key players in morphogenetic events.

Indeed mechanical signaling has been implicated in numerous cellular processes, such as migration or differentiation and number of studies, over the past years, had also pointed out the role of forces during morphogenesis.

Recently the team unveiled the implication of mechanical forces as initiators of fold formation, in the morphogenesis of the distal part of the drosophila leg. Furthermore they have shown that, fold -inducing forces are generated initially by apoptotic cells. Following this exiting discovery, the team now wants to focus on the basal consequences of fold formation. Indeed, ours model allow clear observation of the apical and the basal side of epithelial cells.

This offers the possibilities to study the role of basal attachment and basement membrane in the fold formation process which is particularly interesting since until now the folding process has been mainly described from an apical view.

Using confocal imaging on live and fixed tissue with fusion proteins, we manage to follow the dynamic of the basal side of the leg epithelium (ECM and adhesions). We were also able to access the role of these basal side components during leg morphogenesis thanks to the genetic tools available in drosophila.

Our results shown that the basal components of the leg disc epithelium are highly dynamic and that they are required during the fold formation process.

The aim of my work is to get one step further in the comprehension of mechanical forces and their influence during morphogenetic events such as fold formation and also get a “new” basal side view of this phenomenon.

D1029B Investigating the regulation of the imaginal disc epithelial barrier during regeneration. *Danielle DaCrema*, Ryunosuke Yano, Rajan Bhandari, Adrian Halme. University of Virginia, Charlottesville, VA.

The epithelial barrier, formed by septate junctions in invertebrates, compartmentalizes the body and provides a barrier to pathogens. To sustain distinct compartment environments, the epithelial barrier must be stably maintained. Therefore, we are interested in how epithelia regulate barrier function during tissue regeneration. To address this, we have been examining the dynamics of the epithelial barrier during regeneration in the *Drosophila* wing imaginal disc. Following X-irradiation, we observed a temporary depletion and/or mislocalization of septate junction components in wing discs. Normal localization of these septate junction components is recovered prior to pupation. To determine if the epithelial barrier is also functionally impaired following damage, we examined whether the imaginal disc epithelia of irradiated discs is permeable to a fluorescently-labeled dextran. We observed infiltration of labeled dextran into the lumen of irradiated discs, but not

control discs, indicating that the epithelial barrier is compromised following damage. To determine if this disruption of barrier function in irradiated discs is a physical response to apoptotic damage or a regulated process during regeneration, we irradiated larvae late in larval development after a point when they can no longer initiate regenerative repair on imaginal discs, and examined the localization of septate junction components. Following late irradiation, we observed that septate junction components of imaginal discs are not disrupted or mislocalized; suggesting that septate junction disruption following damage is a regulated process, and dependent on the regenerative activity of the imaginal disc.

We also observed that septate junction disruption causes a synergistic increase in *Drosophila* insulin-like peptide 8 (*dilp8*)-mediated developmental delay. This suggests that the epithelial barrier limits *dilp8* signaling. Dilp8 is upregulated following damage and accumulates in the imaginal disc lumen following expression, but acts on the brain and ring-gland. Therefore, we hypothesize that damage-induced Dilp8 is produced and apically secreted into the lumen of wing imaginal discs, then leaks through disrupted septate junctions to enter the hemolymph and travel to the brain and ring-gland where it signals to regulate developmental timing and growth. It is possible that the subsequent recovery of the epithelial barrier following damage serves as a method to covey the time course of regeneration to the brain and other organs by controlling the release of Dilp8.

D1030C Assembly of septate junctions and midbody displacement during epithelial cytokinesis. *Z. Wang*[1,2], F. Bosveld[1], Y. Bellaiche[1]. 1) Institut Curie, Paris, FR; 2) Sorbonne Universités, UPMC, Paris, FR.

Epithelial cell cytokinesis is coupled to the formation of a new septate junction between the daughter cells, thereby preserving the integrity of the permeability barrier function during proliferation. Here, using live confocal imaging, we studied the formation of bicellular and tricelluar septate junctions during cytokinesis in the notum of Drosophila pupa. We found that the septate junctions are maintained during cytokinesis, and the assembly of the new septate junctions relies on neighboring epithelial cells ingressing in between the two daughter cells, binding and following the movement of the midbody. The detachment of the neighboring cells from the midbody coincides with the maturation of the bicellular and tricellular septate junctions. Our studies reveal how epithelial cells establish new septate junctions during cytokinesis while maintaining septate junctional seals.

D1031A Polo kinase mediates the phosphorylation and cellular localization of Nuf/FIP3, a Rab11 effector. *L. Brose*[1], J. Crest[1,2], L. Tao[1,3], W. Sullivan[1]. 1) University of California, Santa Cruz, Santa Cruz, CA; 2) University of California, Berkeley, Berkeley, CA; 3) University of Hawai'i at Hilo, Hilo, HI.

To understand the mechanisms underlying the cell cycle regulation of vesicle-mediated membrane addition to the cytokinesis furrow, this study follows the localization and regulation of Nuf, a Rab11 effector, in the early *Drosophila* embryo. Nuf, and its mammalian homolog FIP3, is required for activating recycling endosome-based membrane delivery to the cytokinesis furrow. We used molecular genetic, biochemical, cell biological, and fluorescent confocal imaging techniques to determine that Nuf/FIP3 is a phosphoprotein whose pericentrosomal localization is regulated throughout the cell cycle. We show that Polo kinase directly phosphorylates two residues of Nuf, Ser225 and Thr227, and that phosphorylation of these sites correlates with Nuf being driven off the centrosome and into the cytoplasm during prophase, after furrow formation is complete. Further, reduced *polo* expression results in prolonged maintenance of Nuf at the centrosome. Conversely, increased *polo* expression limits Nuf association at the centrosome during interphase.

D1032B A Genetic Dissection of the *Drosophila* Larval Salivary Gland: A Model for Exocrine Gland Physiology. *K. M. Lantz*, M. Al-Karawi, V. Zhitny, A. J. Andres. University of Nevada, Las Vegas, LAS VEGAS, NV.

Exocrine glands are important secretory organs that store specialized cargoes in a limited luminal space until they are released later to the exterior of the animal. The bilobed salivary gland of the *Drosophila* larva is an excellent model for exocrine tissue physiology because each lobe secretes a mix of highly glycosylated glue proteins into a lumen that is connected to a centralized duct. The glue will later be expelled from the animal at puparium formation so that the prepupa can cement itself to a solid surface above the food as it completes it metamorphic stages of development. The stimulus for secretion is a high titer of the insect steroid molting hormone, 20 hydroxyecdysone (20E). Thus, the hormone sets in motion multiple molecular pathways that connect steroid signaling to calcium signaling and cargo activation. This results in a polarized coordinated movement and exocytosis of glue granules at the apical membrane as the tissue undergoes dramatic changes in cell shape. While it is understood that 20E is the cause of cargo exocytosis, little is known about these processes at the molecular level. Using live imaging techniques on cultured dissected tissues compromised for specific genes in the salivary gland, we have begun to identify key components that are 20E regulated. As expected, these proteins are needed to change intracellular Ca^{2+} levels and reorganize the cytoskeleton for long- and short-range movement of glue granules during this important aspect of exocrine physiology.

D1033C Fascin regulates nuclear actin during *Drosophila* oogenesis. *D. J. Kelpsch*[1], C. M. Groen[1,2], T. N. Fagan[1], S. Sudhir[1], T. L. Tootle[1]. 1) University of Iowa, Iowa City, IA; 2) Mayo Clinic, Rochester, MN.

Drosophila oogenesis provides a developmental system to study nuclear actin. During Stages 5-9, nuclear actin levels are high in the oocyte and exhibit dynamic variation within the nurse cells. Cofilin and Profilin, which regulate the nuclear import and export of actin, also localize to the nuclei. Expression of GFP-tagged Actin results in nuclear actin filaments. These findings indicate that nuclear actin must be tightly regulated during oogenesis. One factor mediating this regulation is Fascin. Overexpression of Fascin enhances nuclear GFP-Actin filament formation, and Fascin colocalizes with the filaments. Loss of Fascin reduces, while overexpression of Fascin increases, the frequency of nurse cells with high levels of nuclear actin, but neither alters the overall nuclear level of actin. These data suggest that Fascin regulates nuclear actin dynamics,

allowing specific cells to accumulate nuclear actin. Evidence indicates Fascin positively regulates nuclear actin through Cofilin. Loss of Fascin results in decreased nuclear Cofilin. Additionally, Fascin and Cofilin genetically interact, as double heterozygotes exhibit a reduction in the number of nurse cells with high nuclear actin levels. These findings are likely applicable beyond *Drosophila* follicle development, as the localization and functions of Fascin, and the mechanisms regulating nuclear actin, are widely conserved.

D1034A Hedgehog promotes the production and release of PI(4)P to interact and activate Smoothened. *K. Jiang*, Y. Liu, J. Jia. Univ of Kentucky, Lexington, KY.

The Hedgehog (Hh) signaling pathway plays important roles in both embryonic development and adult tissue regeneration and homeostasis. Inappropriate activation of the Hh pathway has been linked to malignancies such as basal cell carcinoma and medulloblastoma. In *Drosophila*, the Hh signal is transduced through a receptor system at the plasma membrane, which includes the receptor complex Patched-Interference Hh (Ptc-Ihog) and the signal transducer Smo. Binding of Hh to Ptc-Ihog relieves the Ptc-mediated inhibition of Smo, which allows Smo to activate the cubitus interruptus (Ci)/Gli family of zinc finger transcription factors and thereby induce the expression of Hh target genes such as *decapentaplegic* (*dpp*), *patched* (*ptc*), *collier* (*col*) and *engrailed* (*en*). Though Hh signal transduction has been widely studied, it is still unclear how Ptc inhibits Smo to block the activation of the Hh pathway and how Ptc inhibition of Smo is relieved by Hh stimulation. We report here that Hh elevates the production of phosphatidylinositol 4-phosphate (PI(4)P), a specific phospholipid that directly interacts with Smo through an arginine motif in the Smo C-terminal tail and promotes Smo phosphorylation, activation, and ciliary localization. Ptc also interacts with PI(4)P, which is inhibited by Hh stimulation, indicating that Hh triggers the release of PI(4)P from Ptc. We further uncover that Hh induces the production of PI(4)P, likely by regulating PI(4)P kinase and phosphatase. Finally, in addition to the direct role in regulating Smo phosphorylation, G protein-coupled receptor kinase 2 (Gprk2) facilitates PI(4)P interaction with Smo. This study suggest that PI(4)P acts as a special small molecule shuttling between Ptc and Smo to modulate Hh responses.

D1035B Regulation of Smo phosphorylation and high-level Hh signaling activity by a plasma membrane associated kinase. *Shuangxi Li*[1,2], Shuang Li[1,2], Yuhong Han[1,2], Chao Tong[2,5], Bing Wang[1,2], Yongbin Chen[2,4], Jin Jiang[1,2,3]. 1) Department of Molecular Biology,University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 2) Department of Developmental Biology,University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 3) Department of Pharmacology, University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 4) Kunming Institute of Zoology, Chinese Academy of Sciences, Kunming, Yunnan, China; 5) Life Sciences Institute and Innovation Center for Cell Biology, Zhejiang University, Hangzhou, China.

Hedgehog (Hh) signaling controls embryonic development and adult tissue homeostasis through the GPCR-family protein Smoothened (Smo). Upon stimulation, Smo accumulates on the cell surface in *Drosophila* or primary cilia in vertebrates, which is thought to be essential for its activation and function, but the underlying mechanisms remain poorly understood. Here we show that Hh stimulates the binding of Smo to a plasma membrane-associated kinase Gilgamesh (Gish)/CK1γ, and that Gish promotes high level Hh pathway activity by phosphorylating a Ser/Thr cluster (CL-II) in the juxtamembrane region of Smo carboxyl-terminal intracellular tail (C-tail). We find that CL-II phosphorylation is promoted by PKA-mediated phosphorylation of Smo C-tail and depends on cell surface localization of both Gish and Smo. Consistent with CL-II being critical for high threshold Hh target gene expression, its phosphorylation appears to require higher levels of Hh or longer exposure to the same level of Hh than PKA-site phosphorylation on Smo. Furthermore, we find that vertebrate CK1γ is localized at the primary cilium to promote Smo phosphorylation and Shh pathway activation. Our study reveals a conserved mechanism whereby Hh induces a change in Smo subcellular localization to promote its association with and activation by a plasma membrane localized kinase, and provides new insight into how Hh morphogen progressively activates Smo.

D1036C The PARP enzyme Tankyrase antagonizes activity of the βcatenin destruction complex through ADP-ribosylation of Axin and APC2. *H. An*, C. Powers, J. Tran, H. Croy, C. Fuller, J. Giannotti, P. Robinson, A. Foley, R. Yamulla, S. Cosgriff, B. Greaves, R. von Kleeck, A. Tocker, K. Jacob, B. Davis, D. Roberts. Franklin and Marshall College, Lancaster, PA.

Most colon cancer cases are initiated by truncating mutations in the tumor suppressor, Adenomatous Polyposis Coli (APC). APC is a critical negative regulator of the Wnt signaling pathway that participates in a multi-protein "destruction complex" to target the key effector protein βcatenin for ubiquitin-mediated proteolysis. Prior work has established that the Poly ADP ribose Polymerase (PARP) enzyme Tankyrase (TNKS) antagonizes destruction complex activity by promoting degradation of the scaffold protein Axin, and recent work suggests that TNKS inhibition is a promising cancer therapy. We performed a yeast two-hybrid (Y2H) screen and uncovered TNKS as a putative binding partner of Drosophila APC2, suggesting that TNKS may play multiple roles in destruction complex regulation. We find that TNKS binds a C-terminal RPQPSG motif in Drosophila APC2, and that this motif is conserved in human APC2, but not human APC1. In addition, we find that APC2 can recruit TNKS into the βcatenin destruction complex, placing the APC2/TNKS interaction at the correct intracellular location to regulate βcatenin proteolysis. We further show that TNKS directly PARylates both Drosophila Axin and APC2, but that PARylation does not globally regulate APC2 protein levels as it does for Axin. Moreover, TNKS inhibition in colon cancer cells decreases βcatenin signaling, which we find cannot be explained solely through Axin stabilization. Instead, our findings suggest that TNKS regulates destruction complex activity at the level of both Axin and APC2, providing further mechanistic insight into TNKS inhibition as a potential Wnt pathway cancer therapy.

D1037A Proteomic analysis reveals APC-dependent post-translational modifications and identifies a novel regulator of β-catenin. *M. A. Blundon*, D. R. Schlesinger, A. Parthasarathy, S. L. Smith, H. M. Kolev, D. A. Vinson, E. Kunttas-Tatli, B. M. McCartney, J. S. Minden. Carnegie Mellon University, Pittsburgh, PA.

Wnt signaling generates patterns in all embryos, from flies to humans, and controls cell fate, proliferation, and metabolic homeostasis. Inappropriate Wnt pathway activation results in diseases, including colorectal cancer. The *Adenomatous polyposis coli* (*APC*) tumor suppressor gene encodes a multifunctional protein that is an essential regulator of Wnt signaling and cytoskeletal organization. While progress has been made in defining the role of APC in a normal cellular context, there are still significant gaps in our understanding of APC-dependent cellular function and dysfunction. We expanded the APC-associated protein network using a combination of genetics and a proteomic technique called Two-dimensional Difference Gel Electrophoresis (2D-DIGE). We show that loss of *APC2* causes protein isoform changes reflecting misregulation of post-translational modifications (PTMs), which are not dependent on β-catenin transcriptional activity. Mass spectrometry revealed that proteins involved in metabolic and biosynthetic pathways, protein synthesis and degradation, and cell signaling are affected by the loss of *APC2*. We demonstrate that changes in phosphorylation partially account for the altered PTMs in *APC* mutants, suggesting that *APC* mutants also affect other types of PTM. Finally, through this approach Aminopeptidase P was identified as a new regulator of β-catenin abundance in *Drosophila* embryos. This study provides new perspectives on APC's cellular effects that may lead to a richer understanding of APC's role in development and disease.

D1038B Activation of Sona requires furin cleavage and autocatalysis. *S.-S. Lee*, J.-H. Won, G.-W. Kim, K.-O. Cho. KAIST, DAEJEON, KR.

ADAMTS (a disintegrin and metalloproteases with thrombospondin motif) family consists of secreted proteases, and is shown to cleave extracellular matrix proteins. Their malfunctions result in cancers and disorders in connective tissues. We have previously reported that a *Drosophila* ADAMTS named Sol narae (Sona) promotes Wnt/Wingless (Wg) signaling by modifying the activity and diffusion of Wg. Thus, spatiotemporal regulation of Wg signaling may be linked to the regulation of Sona activity. To become an active Sona, the prodomain of Sona has to be cleaved by furin, a proprotein convertase. To understand which processes are important for Sona activation, we generated mutations in five putative furin cleavage sites, three N-glycosylation sites, and carboxyl terminal region, and then examined which mutations affect the activation of Sona. We found that one of the five furin sites is essential for the activation of Sona, and N-glycosylation sites are not important for activation of Sona but for targeting Sona to the destined place. Interestingly, Sona has an autocatalytic site in the prodomain whose cleavage is prerequisite to the cleavage at the furin cleavage site. In addition, the carboxyl terminal region was also important for Sona processing. Taken together, the generation of active Sona requires sequential processing at the autocatalytic site and the furin site.

D1039C The extracellular protease *AdamTS-B* negatively regulates wing vein patterning through BMP signaling. *Afshan Ismat*[1], Minh Pham[2], Mark Schuweiler[1]. 1) University of St. Thomas, St. Paul, MN; 2) Franklin and Marshall College, Lancaster, PA.

Vein patterning in the Drosophila wing provides a powerful tool to study regulation of BMP signaling. Altering levels of BMP effectors can induce major defects in the cross veins and longitudinal veins of wings. The extracellular protease *AdamTS-B* (*CG4096*) encodes an ADAMTS protease expressed in the embryonic trachea and wing imaginal disc precursor cells. The absence of *AdamTS-B* displayed an extra PCV vein, and a branched or incomplete distal tip of the longitudinal L5 vein. These defects were similar to over-expression of BMP agonist *crossveinless* (*cv*), and down-regulation of the BMP inhibitor *short gastrulation* (*sog*). The defects observed in over-expression of *AdamTS-B* were also similar to those of *sog* up-regulation and *cv* knock-down mutations; PCV were not formed completely. Furthermore, the downstream effector of BMP signaling, pMad, showed altered expression levels consistent with the PCV defects seen in the loss and over-expression of *AdamTS-B*. These findings suggest that *AdamTS-B* might be a BMP antagonist, modifying BMP agonists or receptors to alter BMP signals. Further study needs to be undertaken to fully unravel interactions between *AdamTS-B* and BMP signaling.

D1040A Interplay of BMP and JAK/STAT in Developmentally Related Apoptosis. *A. R. Mascaro*, A. Borensztejn, K. A. Wharton. Brown University, Providence, RI.

In the *Drosophila melanogaster* ovary, somatic follicle cells are critical to multiple aspects of oocyte development. The specification of different sets of follicle cells establish signaling centers that not only impact the formation of the micropyle, vitelline envelope, and specific chorion structures, but also play important roles in initiation of the future A/P and D/V axes. A crucial somatic cell type, the stalk cells, form a linear structure that separates consecutive egg chambers as they are produced and continue to develop through each stage of oogenesis. Without stalk cells, egg chambers, composed of a highly organized arrangement of 16 germline cells surrounded by hundreds of specialized somatic follicle cells, can merge. Such merged or 'fused' egg chambers lack organization required for proper patterning and fail to produce a viable oocyte. Thus, the maintenance of stalk cells is critical for *Drosophila* oogenesis. We found that during normal oogenesis the stalk cells comprising a single stalk, or the connection between two egg chambers, are produced in excess and reduce in number as oogenesis proceeds and they bridge increasingly developed egg chambers. We find that this reduction arises as a result of apoptosis, a process critical in many developmental events requiring defined numbers of cells or involved in sculpting organs. Interestingly, while establishing stalks during normal development involves the eliminating of some stalk cells through apoptosis, mechanisms are clearly in place to prevent excessive loss of these cells. We have found that excessive apoptosis is prevented by JAK/STAT signaling, distinct from its proapototic role in defining exactly two polar cells at the anterior and posterior poles of each egg chamber. In addition to JAK/STAT signaling, we find that BMP signaling is also required to inhibit abnormal loss of stalk cells through apoptosis. If either JAK/STAT signaling or BMP signaling is specifically reduced in the stalk cells, we observe a more significant loss of stalk cells, such that the complete fusion of egg chambers may occur. The converse is true when JAK/STAT signaling or BMP signaling is increased. The reduced numbers of stalk cells observed when knocking down JAK/STAT signaling can be rescued through the overexpression of the BMP 5/6/7 ortholog Gbb. Similarly, the 'long' stalks produced by overactivation of JAK/STAT signaling can be suppressed by downregulation of gbb, supporting an intimate relationship between these two signaling pathways in defining the precise number of stalk cells that make up interfollicular stalks.

D1041B The Notch-mediated hyperplasia circuitry in *Drosophila*. *D. M. Ho*[1], S. K. Pallavi[2], S. Artavanis-Tsakonas[1,3]. 1) Harvard Medical School, Boston, MA; 2) Translational Health Science and Technology Institute, Faridabad, India; 3) Biogen Inc., Cambridge, MA.

Notch signaling controls a wide range of cell fate decisions during development and disease via synergistic interactions with other signaling pathways. We performed a genome-wide genetic screen in *Drosophila* and uncovered a highly complex Notch-dependent genetic circuitry that profoundly affects proliferation and consequently hyperplasia. We further examined two novel synergistic relationships, between Notch and either of the non-receptor tyrosine kinases Src42A and Src64B, and between Notch and the transcription factor Mef2. Both interactions promote hyperplasia and tissue disorganization, largely via activation of the JNK pathway, indicating that there are commonalities within the Notch-dependent proliferation circuitry; however, they differ in how they access and interpret the JNK signal. Most notably, whereas Notch-Src causes high levels of apoptosis, Notch-Mef2 does not display this phenotype, thus resulting in a comparatively higher degree of hyperplasia. We examined differential targets of the two synergies to identify downstream anti- or pro-apoptotic factors in Notch-Mef2 or Notch-Src respectively, and identified the transcription factor disco as a potential suppressor of apoptosis in Notch-Mef2 tissues. These findings underscore the complexity and specificity of the Notch signaling network and have potential implications for Notch-related cancers.

D1042C CG9650: A novel regulator of patterning of the Indirect Flight Muscles of *Drosophila melanogaster*. *S. Jawkar*[1], U. Nongthomba[1]. 1) Indian Institute of Science, Bangalore, Bangalore,560012- INDIA; 2) Indian Institute of Science, Bangalore, Bangalore,560012-INDIA.

Myoblasts housed on the notum region of the wing disc undergo cell-lineage dependant specification, proliferation, migration and differentiation to finally generate the two groups of Indirect Flight Muscles (IFMs), i.e. the Dorsal Longitudinal Muscles (DLMs) and Dorsal Ventral Muscles (DVMs). Defects in any of these highly synchronised processes lead to abnormal patterning of the IFMs. CG9650, a gene predicted to be involved in neural development, was found to be highly expressed in proliferating and migrating myoblasts. Tissue specific knockdown of CG9650 led to a defect in the pattern of the IFMs. The function of CG9650 was found to be important in the founder cell population of the myoblasts. Immunostaining for known regulators of IFM patterning indicated a role of CG9650 in regulating the expression of Notch, and subsequently Twist in proliferating and migrating myoblasts. Knockdown of CG9650 also led to an accumulation of Wingless levels. In this study, we provide evidence implicating CG9650 as an important regulator of Notch expression during early IFM development.

D1043A Functional investigation of a late-onset Alzheimer's disease associated variant in TM2D3. *J. L. Salazar*[1], D. Li-Kroeger[1], H. J. Bellen[1,2,3], J. M. Shulman[1,3], J. Jakobsdottir[4], S. Yamamoto[1,3], CHARGE (Cohorts for Heart and Aging Research in Genomic Epidemiology) Consortium. 1) Baylor College of Medicine, Houston, TX; 2) Howard Hughes Medical Institute, Houston, TX; 3) Texas Children's Hospital, Houston, TX; 4) The Icelandic Heart Association, Kopavogur, Iceland.

Alzheimer's disease (AD) is a major cause of dementia that affects more than 44 million people worldwide. Mutations in *APP* and catalytic subunits of the γ-secretase complex (*PSEN1*, *PSEN2*) have been identified as major causes of familial early-onset AD. However, genetic factors that contribute to late-onset AD (LOAD) are mostly unknown. Through an exome-wide genotyping microarray approach, the CHARGE (Cohorts for Heart and Aging Research in Genomic Epidemiology) Consortium identified a novel LOAD-associated risk variant in the *TM2D3* locus within an Icelandic population. Interestingly in *Drosophila*, mutations in *almondex* (*amx*), the fly homolog of *TM2D3*, cause a maternal effect neurogenic phenotype that phenocopy loss-of-function phenotypes of *Notch* and *Presenillin*. However, multiple bioinformatics programs (PolyPhen, SIFT, CADD) predicted that this LOAD associated variant in *TM2D3* is not damaging, raising the question of whether or not this is a true functional variant.

To determine if the LOAD-associated variant in *TM2D3* is functional, we "humanized" the *amx* gene by rescuing the *Drosophila amx* mutants with a genomic rescue construct that encodes human *TM2D3*. Interestingly, while a genomic rescue construct of *amx* that expresses wild-type human *TM2D3* can significantly suppress the maternal effect neurogenic phenotype, the LOAD-variant failed to do so. These results suggest that the LOAD-associated variant in *TM2D3* acts as a loss-of-function mutation in the context of embryonic Notch signaling. Considering that *amx* has been previously implicated to function at the γ-secretase mediated activation step of Notch, we hypothesize that *TM2D3* plays a role in AD through modulation of the β-amyloid pathway.

D1044B The cell-type specific functions of an ER modulating factor, Pecanex in Notch and Wnt signaling pathways. *T. Yamakawa*, P. Das, A. Yamagishi, N. Liu, K. Matsuno. Osaka Univ, Osaka, JP.

Notch (N) signaling is an evolutionarily conserved mechanism that regulates a broad spectrum of cell-specification through local cell-cell interaction. *Drosophila pecanex* (*pcx*) encodes an evolutionarily conserved multi-pass transmembrane protein that is a component of N signaling. We previously suggested that Pcx localizes to the endoplasmic reticulum (ER) and is required for the maturation of N receptor in there. However, the functions of *pcx* in N signaling appears to be context-dependent. Therefore, in this study, we examined the tissue-specific roles of *pcx* in N and other signaling pathways.

First, we examined various cell-fate decision that requires N signaling activity in *pcx* mutant embryos. We found that *pcx* mutant embryos showed abnormalities in the tracheal system, as found in *N* mutant embryos, suggesting that *pcx* is required for N signaling in tracheal development. However, *pcx* was not required for N signaling in the border cells specification of the hindgut and the invagination of the esophagus to the proventriculus.

Unexpectedly, however, the visceral mesodermal cells were missing in *pcx* mutant embryos, whereas *N* mutant embryos showed an increase in them as compared with wild-type. These results suggested that *pcx* is required for a different signaling pathway, besides N signaling. Because mutant embryos of *wingless*, which encodes a ligand of Wnt signaling, showed the missing of visceral mesodermal cells, it is likely that *pcx* may

be required for Wnt signaling in the visceral mesoderm. In addition, we found that the ER of phagocyte was enlarged in *pcx* mutant embryos. However, N signaling is not required for the phagocytic development during embryogenesis, and *N* mutant embryos did not show the ER enlargement phenotype. Thus, we speculated that *pcx* may function independently of N signaling in phagocytic development. From these results, we concluded that *pcx* plays cell-type specific functions in N and Wnt signaling pathways.

D1045C An *in vivo* screen for novel small molecule inhibitors of PLCγ. *Chitra Naidu*, Michelle Latino, Claire Rosenwasser, Todd Rosenberg, Justin Thackeray. Clark University, Worcester, MA.

PLCγ is a key signaling molecule that regulates pathways required for cell proliferation, differentiation and apoptosis. Various studies have reported PLCγ overexpression to be a key factor in transforming primary tumors to metastatic by affecting these very pathways. A PLCγ-specific inhibitor could therefore be an invaluable tool not only for basic research but also for anti-cancer studies.

Small wing (*sl*), the *Drosophila* homolog of *PLCγ*, plays a dual role. It negatively regulates the EGFR pathway controlling photoreceptor and wing vein differentiation while positively regulating the Insulin pathway affecting growth. An *sl* null mutant (sl^9/sl^9) shows a reduced wing size, ectopic veins and rough eyes as a result of extra R7 photoreceptors in ~60% ommatidia. Our objective is to identify a novel small molecule inhibitor of PLCγ using *Drosophila* as a model system.

In a primary screen, we looked at vein differentiation patterns to identify molecules that alter EGFR signaling. Argos, an inhibitor of EGFR, when overexpressed in wings causes severe loss of venation which is significantly rescued in L3 by a partial loss of Sl function. Thus, drug fed MS1096>Aos flies were used as a sensitive model system to detect potential Sl inhibition by looking for L3 vein recovery. 37 of the 1,596 small molecules, provided by the NCI, showed significant results.

We are currently in the process of performing secondary screens to confirm EGFR inhibition by looking at photoreceptor differentiation in the eye in an sl^7 mutant. sl^7 is a missense mutation that results in 5-10% ommatidia with extra R7 photoreceptors. Further inhibition of Sl or the EGFR pathway would result in a higher percentage of R7 recruitment. So far, we have identified 7 small molecules as potential inhibitors. In conjunction, these molecules are also being tested on homozygous *rolled* (rl^1) mutants. rl^1 flies have a disrupted EGFR pathway and exhibit ~22% ommatidia without R7's. Amplification of the EGFR pathway, potentially through Sl inhibition would result in a recovery of photoreceptor numbers. Subsequent experiments will try to determine whether any of the small molecules identified do in fact inhibit Sl.

D1046A The COP9 signalosome regulates EGFR signaling by stabilizing Capicua. *A. Y. T. Suisse*, D. Q. He, K. Legent, J. E. Treisman. Skirball Institute of Biomolecular Medicine, NYU, New York, NY.

Post-translational modifications that alter protein activity are essential for signal transduction in many signaling pathways. The Epidermal Growth Factor Receptor (EGFR) pathway uses a kinase cascade to activate Mitogen-Activated Protein Kinase (MAPK) by phosphorylation. Phosphorylated MAPK can translocate into the nucleus and activate the transcription of target genes. In the *Drosophila* wing disc, the effect of MAPK on its target gene *argos* (*aos*) is mediated by phosphorylation and inactivation of the transcriptional repressor Capicua (Cic). Phosphorylated Cic can be exported from the nucleus and/or degraded.

In a genetic screen for regulators of EGFR signaling, we found two mutations in the *csn1b* gene. Loss of *CSN1b* leads to ectopic activation of the EGFR target gene *aos* in the wing disc. *csn1b* encodes a subunit of the COP9 signalosome (CSN), a complex that removes Nedd8 (a Ubiquitin-like protein) from substrates. The best characterized substrates for the CSN are Cullins (scaffold subunits of E3 ubiquitin ligases), which are active in their neddylated state. *aos* is also misexpressed in the absence of other CSN subunits, and this misexpression requires a basal level of EGFR signaling.

We have traced the effect of the CSN on *aos* to its positive regulation of Cic stability. Cic levels are reduced in cells lacking CSN subunits, and the expression of other Cic target genes, including *cyclin E* and an artificial reporter, is increased. Interestingly, removing the MAPK docking site from Cic protects it from degradation in *csn5* mutant cells, but not in *csn1b* mutant cells, suggesting the existence of two separate degradation mechanisms.

We are now investigating the mechanisms by which the CSN regulates Cic levels. The activity of Cullin-based ubiquitin ligases appears to be increased in *CSN* mutant cells, suggesting that a Cullin complex could ubiquitinate Cic and send it to 26S proteasome-mediated degradation. Alternatively, another type of ubiquitin ligase, or Cic itself, could be a substrate for deneddylation by CSN. As human Cic is a tumor suppressor gene, these results may shed light on the role of the CSN in cancer.

D1047B Yki interacts with the JNK pathway to regulate epidermal wound healing in *Drosophila* larvae. *C. Tsai*[1,2], A. Anderson[2], S. Burra[2], M. Galko[2]. 1) Baylor College of Medicine, Houston, TX; 2) MD Anderson Cancer Center, Houston, TX.

To cope with inevitable injury, organisms possess efficient wound healing mechanisms to maintain tissue integrity and guard against infection. However, the cellular and molecular details by which wound healing is accomplished remain poorly defined. *Drosophila* melanogaster serves as a great model organism to study wound healing because of the versatile genetic tools available and the simple anatomy of the epidermal barrier. Upon larval epidermal wounding, epidermal cells around the wound elongate and migrate in the absence of cell division to ultimately close the wound. Using the wound closure assay we established, we found the Hippo downstream transcriptional regulator, Yorkie (Yki) and its TEAD binding partner Scalloped (Sd) to be required for epidermal wound healing. Intriguingly, unlike in other regenerative contexts, Yki does not regulate the balance of mitosis or apoptosis in the healing larval epidermis. Rather, it seems to regulate actin polymerization in the migrating wound-edge epidermal cells. Moreover, with a series of genetic analyses, we found that Yki has a strong genetic interaction with another wound closure signaling, the Jun N-terminal Kinase (JNK) pathway. Our results suggest that there is a positive feedback loop between these two pathways to facilitate proper epidermal wound healing.

D1048C Identification and characterization of novel epidermal growth factor receptor target genes implicated in *Drosophila* development. *Michael Warkala*, John Nawrocki, Sergey Svintozelskiy, Sean Thomas, Lisa Kadlec. Wilkes University, Wilkes-Barre, PA.

Signaling by the *Drosophila* epidermal growth factor receptor (Egfr) plays an important role in many aspects of development, including oogenesis, embryogenesis and proper development of both the eye and the wing. In the ovary, the Egfr pathway is known to play a key role in the establishment of the body axes during oogenesis. In the wing, Egfr signaling plays an important role in vein tissue specification, and in the eye it has been found to be important for photoreceptor cell differentiation. Microarray screens by our lab and others have been used to identify potential downstream transcriptional targets of the Egf receptor using the *Drosophila* ovary as a model system. Our initial work compared gene expression using fly ovaries in which the activity of the Egfr-pathway was reduced (*grk* mutant), normal (OreR), or constitutively active (CY2/λTop). We have employed a number of approaches to further investigate the expression, biological function, and mechanism of action of an initial set of putative genes of interest, focusing primarily on genes of previously unknown function. Several of these targets exhibit developmentally regulated expression in the ovary. UAS-RNAi was used to knock down expression of various target genes in either specific tissues or ubiquitously via a tubulin driver. Gene knockdown phenotypes include abnormal wing morphology, decreased eggshell integrity, and, in at least one case, lethality. We are currently extending our studies by utilizing the UAS/Gal4 system to perform a functional screen of previously identified, but untested, target genes whose expression is highly upregulated in response to constitutive Egf receptor activity. In particular, the available libraries of UAS-RNAi transgenic flies are being used in concert with ovarian and wing disc Gal4 driver lines to identify additional genes with roles in *Drosophila* developmental events. We have identified several additional genes which may have roles in normal eggshell formation. RT-PCR has confirmed the up-regulation of some of our newly identified targets, and we are further investigating gene expression patterns via *in situ* hybridization.

D1049A The Rap Guanine Nucleotide Exchange Factor (GEF) C3G is required for nephrocyte function in *Drosophila melanogaster*. *C. Picciotto*[1], C. P. Dlugos[1,2], A. Jeibmann[3], M. Krahn[4], R. Wedlich-Söldner[2], H. Pavenstädt[1], C. Klämbt[5], B. George[1]. 1) Medizinische Klinik D, University Hospital Münster, Germany; 2) Institute of Cell Dynamics and Imaging, University of Münster, Germany; 3) Institute of Neuropathology, University Hospital Münster, Germany; 4) Institute of Molecular and Cellular Anatomy, University of Regensburg, Germany; 5) Institute of Neurobiology, Westfälische-Wilhelms University Münster, Germany.

Introduction and Aim: Glomerular epithelial cells (podocytes) are essential for kidney filter function. Podocyte defects are central to many chronic glomerular diseases and are characterized by aberrant intercellular junctions (slit diaphragms) and actin cytoskeletal dynamics. Patients expressing mutated variants of the slit diaphragm protein Nephrin fail to develop functional slit diaphragms, due to signaling defects to the podocyte actin cytoskeleton. *Drosophila* nephrocytes form a filtration barrier, express the Nephrin orthologue Sticks and stones (Sns), and serve as a genetically tractable model for mammalian podocytes. The aim of our study is to analyze Nephrin signal transduction.
